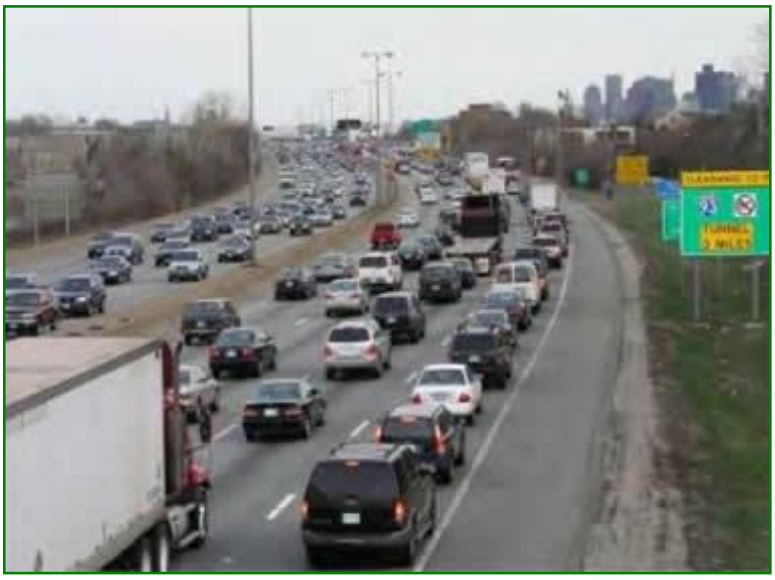
Executive Summary

Background



Lessening severe traffic along the highways connecting New Hampshire and Massachusetts is a main project goal

The need for this Capitol Corridor Rail and Transit Alternatives Analysis (AA) along the 73-mile stretch from Concord, New Hampshire to Boston, Massachusetts has been growing for decades. While the Massachusetts Bay Transportation Authority (MBTA) commuter rail service currently operates between Boston and Lowell, commuter rail passenger service north of Lowell ceased in 1967. Since then, however, the Boston commuter-shed steadily expanded north into Nashua and Salem, and is continuing even further northward into Manchester and Concord. Sprawl-type suburban residential development patterns, which rely heavily on auto travel, have emerged, yet business development and job creation, especially in high-technology sectors, have been stagnant in the corridor's northern half. The Capitol Corridor's robust transportation network includes roadways, highways, transit services, intercity passenger rail service, freight railroads, airport, and pedestrian and bicyclist facilities. Despite the dense, multi-modal nature of this transportation network, demand is exceeding capacity – particularly within the highway network.

As Boston stands strong as the region's largest economic hub, people living north of Lowell and working in metropolitan Boston are singularly reliant on roadways to commute to work. The result is severe traffic congestion along limited access highways connecting New Hampshire's major population centers to metropolitan Boston – I-93, Route 3/Everett Turnpike, Route 128/ I-95, I-293, and I-495. During peak morning hours, southbound travel speeds average less than 30 miles per hour (mph), traffic volumes exceed roadway capacity by more than 25 percent, and average speeds within eight miles of Boston dip to as low as 12 mph. Based on historical data, traffic volumes are projected to continually increase and additional highway expansion is unlikely due to financial and environmental constraints.

Project Goals and Objectives

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life led New Hampshire and Massachusetts citizens and officials to explore options to improve transit service along the Capitol Corridor's northern end.

Early in 2013, the New Hampshire Department of Transportation (NHDOT), working in concert with its counterparts in Massachusetts, started this 21-month Capitol Corridor AA with support and funding from the Federal Railroad Administration (FRA) and Federal Transit Administration (FTA). The Study evaluated a diverse set of rail and bus options for improving connectivity in the corridor by leveraging existing transportation infrastructure and integrating transportation and land use planning.

AA Study goals and objectives (Figure 1 on the next page) reflect an understanding of how this integrated planning can support economically, environmentally, and socially sustainable communities within the corridor.

Project Organization and Funding

This 21-month AA Study was supported and funded by the FTA and FRA so the broadest possible set of alternatives (bus- or rail-based transit service and intercity passenger rail service) was considered to meet corridor transportation needs. While these two funding streams support the one AA Study, each agency designated use of their funds for specific tasks and geographies:

1. **FTA** funding was limited to AA tasks related to transit service in the Concord-Boston corridor and included developing a range of alternatives for travel from Concord, Manchester, and Nashua to Boston; soliciting and evaluating public outreach and input on those alternatives; and developing recommended strategies along with an Environmental Assessment (EA) of those alternatives.

2. To fully evaluate the intercity rail alternative, **FRA** funding was used to develop and screen alternatives, identify and analyze travel markets, and review existing services for the full 73-mile corridor. Tasks were limited to examining intercity rail alternatives in the corridor between Boston and Concord and included developing a Service Development Plan (SDP) and an EA, both of which require FRA approval.

Figure 1 – AA Goals and Objectives

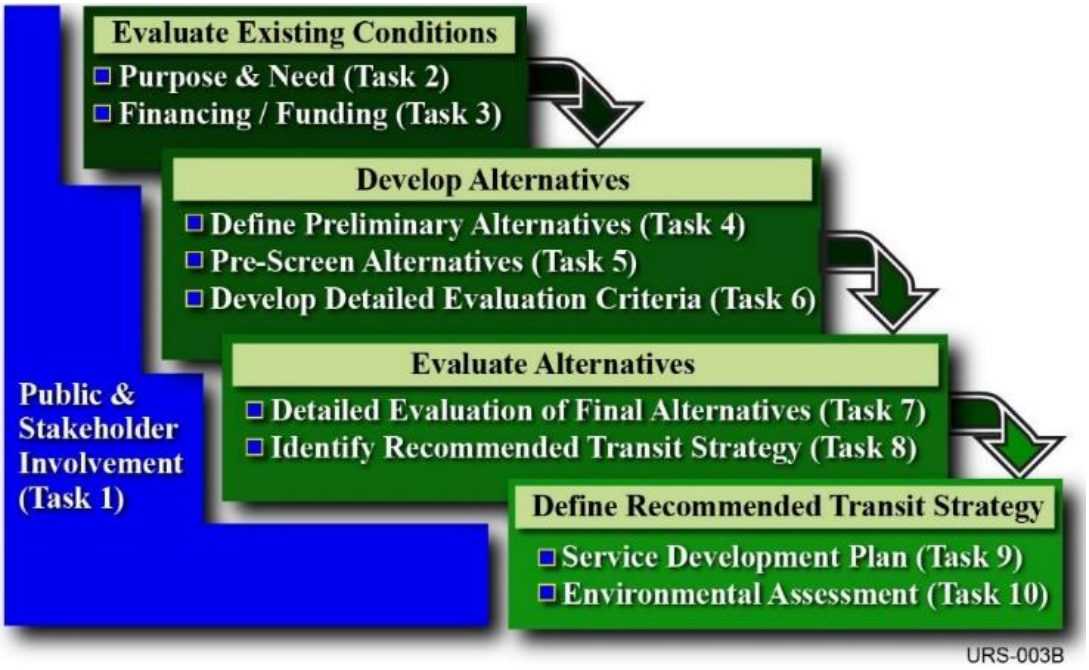
Goals	Objectives
Transportation and Mobility *Leverage the existing transportation network to improve access and mobility within the corridor and throughout the region*	▪ Provide alternatives to address congestion within the Study corridor ▪ Expand transit network capacity ▪ Increase transit ridership/mode-share by expanding existing rider base and attracting new riders ▪ Provide travel time savings ▪ Improve transit service efficiency, convenience, and reliability
System Integration *Invest in transportation improvements that complement the existing multi-modal transportation network*	▪ Increase corridor modal connectivity ▪ Provide connections to other corridors within the region ▪ Increase access to Manchester-Boston Regional Airport (Manchester Airport) through additional transit service ▪ Balance system capacity (MBTA, Boston Express [BX], Concord Coach) ▪ Ensure operating efficiency
Economic Development and Land Use *Support the vision for growth laid out in local/regional development plans*	▪ Improve access to higher-paying jobs in greater Boston ▪ Support development patterns/lifestyle choices that attract younger, highly educated professionals to New Hampshire ▪ Leverage younger, highly educated employee base to attract new businesses/grow existing ones ▪ Promote Transit-Oriented Development (TOD) to mitigate sprawl development patterns ▪ Improve the potential for additional freight rail business through infrastructure upgrades
Sustainability *Support transportation investments that contribute to an environmentally, economically, and socially sustainable community*	▪ Leverage existing infrastructure to qualify for federal transportation investment dollars ▪ Mitigate potential adverse environmental impacts resulting from anticipated development ▪ Support growth patterns that attract/retain residents from childhood through retirement ▪ Improve access to other tourism, recreation, and cultural attractions in greater Boston and New Hampshire

Project Process

To develop a preferred transit investment strategy for the Capitol Corridor, the Study team and NHDOT conducted 10 tasks in four phases (Figure 2):

1. Evaluate Existing Conditions
2. Develop Alternatives
3. Evaluate Alternatives
4. Define Recommended Transit Strategy

Figure 2 – AA Study Process



Task 1, Public and Stakeholder Involvement, spanned all four phases.

Each task is briefly described below, in more detail in sections of this Final Report, and in greater detail in all Appendices.

1. **Task 1 Public and Stakeholder Involvement** – As is typical with transit alternative studies, the Capitol Corridor AA attracted significant interest from public and private stakeholders throughout the region; members of the general public; and federal, state, and local regulatory agencies. The stakeholder outreach process was proactive and consistent over the 21-month Study. NHDOT and the Study team conducted 91 stakeholder meetings, three Project Advisory Committee (PAC) meetings, and three public meetings (in Concord, Manchester, and Nashua); developed a project website; and held frequent informal discussions to solicit input from all stakeholders.

2. **Task 2 Purpose and Need Statement** – To meet FTA/FRA expectations and as a foundation for eventual National Environmental Policy Act (NEPA) documentation, the Study team developed a clear, defensible definition of transportation and related problems that transit alternatives would address. Past forecasting studies were reviewed, the existing transportation network was defined and documented, demographic data was compiled, and surveys of existing corridor bus and rail service were conducted (market analysis).

3. **Task 3 Financial Plan** – The corridor investment financial plan identified realistic sources of federal and non-federal funding for capital and operations and maintenance (O&M) costs. The plan satisfies FTA requirements for a New Starts submittal and FRA requirements for a SDP, and is politically realistic in terms of existing and future conditions at state and local levels.

4. **Task 4 Initial Conceptual Transit Alternatives** – Conceptual alternatives build upon previous work, including the *Nashua Commuter Rail Study*, the *I-93 Transit Investment Study*, and several Manchester passenger rail studies. The team analyzed rail and highway/bus infrastructure upgrades to address the conditions, problems, and goals and objectives described in the Purpose and Need Statement, and developed 12 initial bus and rail alternatives.

5. **Task 5 Evaluation of Conceptual Alternatives and Recommended Alternatives for Detailed Evaluation** – The 12 initial alternatives were rated against several criteria: capital and O&M costs, ridership, land use and economic development impacts, environmental fatal flaws, and a cost-benefit ratio (i.e., how successfully an alternative delivers greater benefits at a comparatively low cost); this evaluation formed the basis for refinement and advancement into seven intermediate alternatives that would undergo a more detailed evaluation.

6. **Task 6 Evaluation Criteria and Methodology** – To evaluate the seven intermediate alternatives, five criteria categories were identified and defined: economic impacts, land use (including environmental impacts), equity impacts, financial considerations (costs and feasibility of a financial plan/public support of that plan), and mobility impacts (including ridership forecasts).

7. **Task 7 Detailed Evaluation of Alternatives** – Seven of the strongest alternatives were ranked, compared, and assessed against the refined evaluation criteria defined in Task 6.

8. **Task 8 Identification of the Recommended Strategy** – The logical, sequential, analytical selection process (Tasks 4 through 7) culminated in selection of a corridor transit investment strategy that meets NHDOT and stakeholder objectives, is likely to receive state and local financial support, and is likely to qualify for federal capital funding.

9. **Task 9 Service Development Plan (SDP)** – Based on the preferred corridor transit investment strategy, the Study team integrated results of previous tasks into an FRA SDP that complements the AA report. The SDP summarizes AA Study rationale, existing conditions, preliminary and final alternatives analysis, the rationale for selecting the intercity rail option, and an operations strategy and implementation plan.

10. **Task 10 Environmental Assessments (EAs)** – Two EAs were prepared: one to satisfy FRA funding requirements to develop an intercity preferred option and the other to satisfy FTA funding requirements in narrowing transit alternatives.

    Both EAs accomplish four objectives:

    1. Provide for preparation of required NEPA documentation for submission by NHDOT to determine which aspects of transit and intercity rail alternatives have potential for social, economic, or environmental impact
    2. Identify measures that might mitigate adverse environmental impacts
    3. Identify other environmental review and consultation requirements that should be performed concurrently with the EA
    4. Summarize public involvement and the results of agency coordination

Summary of Recommended Strategies

As the Study progressed, 12 conceptual transit alternatives were reduced to seven, and then to five – No Build, Manchester Regional Commuter Rail, Nashua Minimum Commuter Rail, Intercity 8, and Bus on Shoulder (for existing intercity bus service) – which represent the recommended potential transit investment strategies (see Figure 3).

Figure 3 – Rationale for Alternatives Recommended for Further Review and Analysis

Alternative	Rationale for Selection
No Build	Maintenance of the status quo, including existing intercity bus service, is the lowest-cost (in terms of new investment dollars) alternative of all those considered.
Manchester Regional Commuter Rail	Considering the complete range of benefits, this option is the strongest alternative: Manchester Regional Commuter Rail performs very well in terms of ridership, economic development, and land-use impact; however, it is one of the most expensive options.
Nashua Minimum Commuter Rail	Lowest-cost commuter rail option: while it does not stand out in terms of ridership and economic or land-use impacts, Nashua Minimum Commuter Rail could serve as the first phase of Manchester Regional Commuter Rail service implementation.
Intercity 8	Lowest-cost intercity rail option; if implemented, Intercity 8 could serve as the first phase of more robust service similar to the original Amtrak Portland-Boston *Downeaster* service. As a relatively expensive alternative, Intercity 8 would require federal support for capital costs; while there is currently no source for such funds, if that situation changes, then Intercity 8 may be feasible.
Bus on Shoulder	Low on cost, low on benefits, and dependent on a decision by Massachusetts – as construction of any required Bus on Shoulder lanes on I-93 would be close to Boston. The possibility of New Hampshire financial support and reducing existing bus service if rail is implemented should be part of future policy discussions.

These recommended options do not have to be considered as singular investment packages. Bus on Shoulder could be implemented without movement on passenger rail, and rail could be recommended without Bus on Shoulder action. Similarly, Nashua Minimum Commuter Rail could be adopted as the first phase of the Manchester Regional Commuter Rail service – or as an independent project, and Nashua Minimum could be recommended with or without phasing.

Satisfying Regulatory Requirements and Project Stakeholders

A broad spectrum of federal and state regulatory requirements and/or guidance were considered and addressed during development of the Financial Plan (Task 3), SDP (Task 9), and EAs (Tasks 10a and 10b).

For example, to prepare EAs for build and no-build alternatives for intercity rail services (FRA) between Boston and Concord and commuter rail services (FTA) between Boston and Manchester, the Study team followed the Council on Environmental Quality's (CEQ) regulations for *Implementing the Procedural Provisions of NEPA* (40 CFR 1500-1508); the FRA's *Procedures for Considering Environmental Impacts*, 64 FR 28545 (May 26, 1999); and the FRA's guidance on compliance with Service-level NEPA in *Implementing the High-Speed Intercity Passenger Rail Program*, issued August 13, 2009.

Service-level NEPA "typically addresses the broader questions relating to the type of service(s) being proposed, including cities and stations served, route alternatives, service levels, types of operations (speed, electric, or diesel powered, etc.), ridership projections, and major infrastructure components."

The EAs were further prepared in accordance with these requirements:

Examples of Regulatory Requirements and Guidance Reviewed / Followed Throughout the AA Study

- ✓ FTA 5309 Capital Investment Grant (CIG) (New and Small Starts) Program
- ✓ FTA 5337 State of Good Repair (SGR) Grants
- ✓ Federal Highway Administration (FHWA) National Highway Performance Program (NHPP)
- ✓ FHWA Congestion Mitigation and Air Quality Improvement Program (CMAQ)
- ✓ FRA High-Speed Intercity Passenger Rail Program (HSIPR)
- ✓ FRA Railroad Rehabilitation and Improvement Financing (RRIF)
- ✓ U.S. Department of Transportation (USDOT) Transportation Investment Generating Economic Recovery (TIGER)
- ✓ NEPA and NHPA
- ✓ CAA and CWA
- ✓ National Ambient Air Quality Standards
- ✓ Various state regulations (e.g., New Hampshire Department of Environmental Services (NHDES) Env-Wq 1700 and Massachusetts Surface Water Quality Standards, 314 CMR 4.00)

- Section 106 of the National Historic Preservation Act of 1966 (NHPA), as revised in 36 CFR Part 800 (August 5, 2004)
- Section 4(f) of the Department of Transportation Act
- The Clean Air Act (CAA)
- The Endangered Species Act
- The Clean Water Act (CWA)

- Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority and Low Income Populations*
- Executive Order 11990, *Protection of Wetlands*; Executive Order 11988, *Floodplain Management*
- Other relevant requirements for the protection and stewardship of the environment

The project selected for advancement (i.e., either intercity or commuter rail) may undergo additional analysis, which may be an Environmental Impact Statement (EIS), EA, or Categorical Exclusion (CE), depending on project details and the significance of the impact.

Public and stakeholder outreach began at Study initiation and was proactive, consistent, and timely over the 21-month Study lifecycle to fully engage the public and key stakeholders.

In addition to satisfying regulatory requirements, the AA Study sought to inform project stakeholders, and keep them informed. Due to the Capitol Corridor's geographic span (73 miles between Boston and Concord, New Hampshire), the Study attracted significant interest from public and private stakeholders throughout the region, as well as members of the general public. Federal, state, and local agencies with regulatory authority were contacted throughout the process to provide input and comment. In addition, NHDOT identified quasi- and non-governmental stakeholders, and solicited comments through public information meetings, Project Advisory Committee (PAC) meetings, a project website, and other outreach activities.

Next Steps

Based on the analysis completed for this Study and on progress made in the decision-making process in New Hampshire, the Study team concluded that additional discussion, debate, and input by state policymakers is required before a definitive decision on a recommended strategy is made.

In the context of moving toward and making that recommendation, it is especially important that further progress be made on a financial plan, or plans, that could include federal, state (New Hampshire and Massachusetts), and local support. Specific project development actions will emerge as policymakers get closer to a recommended strategy, since alternative strategies can have very different requirements for engineering and project development/management, including identification of governance entities to lead implementation activities and operations.

Report Organization

This New Hampshire Capitol Corridor Rail and Transit AA (Parts A & B) Final Report is a summary of research and analysis conducted over the last 21 months.

Eleven individual technical reports, reflecting 10 project tasks (2 EAs), were produced during that time; therefore, cost and other estimates provided in the technical reports reflect the date they were calculated (see Figure 4).

Each Final Report Section corresponds to each task and technical report, and complete technical reports are provided in corresponding Final Report Appendices as summarized in Figure 4.

Figure 4 – Final Report Organization

Section 1: Public Involvement Report

Task Objective

To convey information about this AA and gain an understanding of stakeholders'/the public's perception of the Study, the Study team and NHDOT conducted three PAC meetings, 91 stakeholder meetings, and three public meetings (in Concord, Manchester, and Nashua) over 21 months.

Three public meetings held over the course of the AA Study enabled NHDOT and the Study team to share project progress and gain an understanding of the public's concerns

1. The PAC consisted of 20 organizations (e.g., Amtrak; the Cities of Concord, Manchester, and Nashua, New Hampshire; Manchester Airport; MBTA; Pan Am Railways [PAR]; and several planning commissions) who met at the conclusion of major Study milestones
2. One-on-one interviews and group briefings were held early in the Study with representatives of 51 stakeholder groups identified by the Study team in consultation with NHDOT
3. Public meetings were held in June 2013, March 2014, and November 2014 in Manchester, Concord, and Nashua, New Hampshire

Other outreach activities included developing and maintaining a project-specific website, http://www.nhcapitolcorridor.com, to disseminate and receive information and sending notices to local media outlets (print [e.g., the Concord Monitor and Nashua Telegraph], broadcast television [e.g., WBIN, Concord and WMUR, Manchester], and radio [e.g., WEVO 89.1 FM, Concord and WGIR 610 AM, Manchester]) to provide notice of upcoming meetings.

A full listing of all 20 PAC members, 51 stakeholder groups, and the 97 outreach activities conducted from Study inception to conclusion is provided in Appendix 1.

In addition to the need for a transparent project process, the following are 10 of the most frequent agency and stakeholder comments and concerns (for a more complete compilation, see Appendix 1):

1. New Hampshire would benefit from a transportation system that provides multiple transit options, is less focused on single occupancy vehicles, and provides an increase in options that have the potential to ease traffic congestion and save commuting time.
2. The Manchester Airport is an important cog in the New Hampshire economy and a rail connection to the airport should be part of the Study.
3. The State needs to work to attract and retain young professionals, who are now leaving New Hampshire at a faster rate than they are moving to the State.
4. It is important to demonstrate the impacts and benefits of passenger rail to the State (economic, social, and environmental).
5. The project needs to have a solid financial plan.
6. State demographics are changing (the population is getting older), and the transportation system needs to address the needs of this changing demographic.
7. The location of potential rail stations is important to many of the communities, and they would like to be part of the discussion in identifying appropriate locations.
8. System safety needs to be analyzed.
9. The fare structure for any system needs to be competitive with other forms of transportation.
10. The frequency of operation needs to be competitive with other forms of transportation.

Section 2: Project Purpose and Need

Study Impetus and Task Objective

While regular passenger rail service between Concord, New Hampshire and Boston, Massachusetts (the Capitol Corridor) ended in 1967, the Boston commuter-shed steadily and continually expanded north into Nashua and Salem, New Hampshire over the past 37 years – and shows no signs of slowing. Perversely, people moved, but businesses did not: job creation in the corridor's northern half (New Hampshire) has not kept pace with residential growth, especially in high-technology sectors flourishing in the corridor's southern half (Massachusetts).

Although the corridor is serviced by roughly 50 daily bus round trips, bus service is not attractive to a broad enough market and cannot keep pace with commuters' needs. Traffic congestion along the five major highways connecting New Hampshire and Massachusetts has increased dramatically despite highway expansion: for example, during the peak morning commute, southbound traffic speeds average less than 30 mph, traffic volumes exceed roadway capacity by more than 25 percent, and average speeds within eight miles of Boston dip as low as 12 mph.

Why Conduct This Study?

- ✓ Projected population growth will increase roadway congestion
- ✓ New Hampshire's existing transportation network does not effectively connect modes
- ✓ The regional economy is singularly dependent on roads for movement of goods and passengers
- ✓ Improved transportation options will attract employers to New Hampshire and improve employment options for residents
- ✓ Improved transit connectivity will help attract and retain young professionals in New Hampshire
- ✓ New Hampshire's growing senior population needs shared transportation accommodations that support "car-light" mobility
- ✓ Growing residential development patterns may negatively impact the region's existing quality-of-life
- ✓ The existing transportation network cannot accommodate increased levels-of-demand without negative environmental consequences

Increased transportation demand, concerns about mobility and quality-of-life, and the residential/employment disconnect led New Hampshire and Massachusetts citizens and officials to embark on this Study as a first step in improving transit service along the Capitol Corridor.

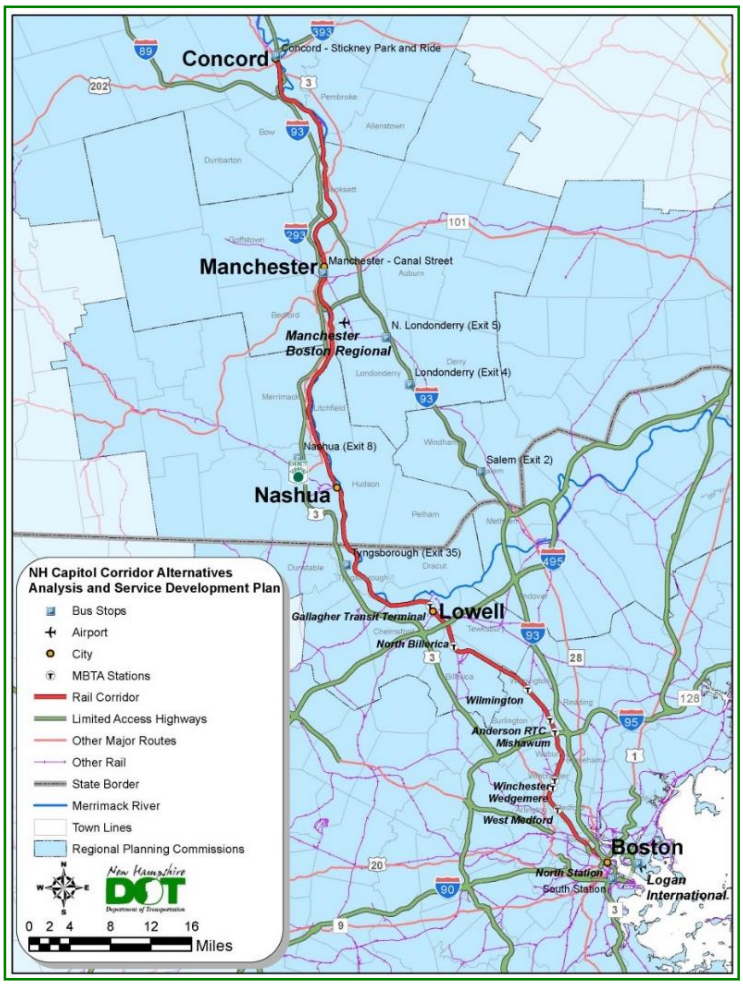
In Task 2, the Study team conducted in-depth research on the corridor's historical and current demographics, travel demand, and land use and sustainability goals to define the project's purpose and need. The AA Study is designed to identify a transit and/or intercity passenger rail investment strategy that leverages existing infrastructure to improve connectivity to and from Boston, diversify options and reduce single-mode reliance on roadways to move people and goods, support mobility options that match emerging demographic trends, and maintain the region's high quality-of-life through strategic infrastructure investments.

Corridor Description

The 73-mile Capitol Corridor (Figure 5) stretches from Boston to Concord. Corridor demographics can be summed as follows:

- Population in this area is increasing – projected growth over 2010-2035 is expected at 10.2 percent.[1]
- Historical patterns based on U.S. Census data from 2000 and 2011 indicate that the percent of New Hampshire's population that falls between the ages of 35-64 is higher than in the U.S., New England, or Massachusettts – and this trend is expected to continue; it is also expected that the over-65 population will continue to grow in New Hampshire – as it increased nearly 20 percent from 2000-

Figure 5 – 73-Mile Capitol Corridor from Boston, MA to Concord, NH



[1] Metropolitan Planning Council, Northern Middlesex Council of Government, Merrimack Valley Planning Commission, New Hampshire Office of Energy and Planning/Central New Hampshire Regional Planning Commission

2011 (about five percent faster than in the U.S. overall and 15 percent faster than in Massachusetts).

- 14 percent of Massachusetts corridor households are zero-car households compared to four percent in New Hampshire.
- The population living below the poverty line is expected to increase, as the New Hampshire population in the corridor living below the poverty line rose 18 percent from 2000-2011.

As demographic trends reflect economic trends, the difference in Massachusetts and New Hampshire corridor employment opportunities is noteworthy: the fastest growing industries in Massachusetts are finance, professional, and scientific/technical, but in New Hampshire they are health care and social assistance, likely reflecting employment choices by "Millennials." Like the Baby Boomers before them, the sheer size of the Millennial generation, those born between approximately 1982 and 2003, means their preferences (e.g., built environments that support a car-light or car-free existence in urban, walkable neighborhoods) will shape every aspect of the region's economy and culture in the coming decades.

Millennials are the rising "creative class" – workers whose career orientation leans towards ideas and innovation rather than heavy manufacturing. As businesses, particularly technology-oriented businesses, look for lower-cost alternatives to downtown Boston and more Millennial-friendly environments than in the Route 128 corridor, Capitol Corridor communities can increase their attractiveness through transit investment. Improved connectivity will improve access to Boston-based employment and draw "creative class" workers, and the companies that want to hire them, into the New Hampshire corridor.

Travel Demand, Land Use, and Sustainability

Capitol Corridor transit investment can be the tool that implements a regional, multi-discipline vision to maintain and promote a high quality-of-life. To do that, the improved corridor transit investment strategy resulting from this AA Study must account for increased travel demand, efficient land use, and sustainability.

Travel Demand

Travel from New Hampshire to Boston is predominately made by auto trips in one of two main corridors: either I-93 or a combination of US Route 3, Route 128/I-95/I-93 – and that travel is expected to increase significantly between now and 2030.

For example, the Boston Metropolitan Planning Organization's (MPO's) travel demand model forecasts that average daily highway trips into Boston from the north and northwest, which include the Massachusetts portion of the Study corridor, will increase approximately six percent; travel on Route 3 is expected to rise by 37 percent; and I-93 traffic volumes by 19 percent.[2]

In the New Hampshire portion of the Study corridor, the Manchester MPO forecasts traffic volumes to increase by 15 percent along I-93 in Manchester and 76 percent in Derry by 2040. Along Route 3 in Bedford it is expected to increase by 55 percent by 2040.[3] Simply expanding the roadway network is not a solution as it would likely induce additional demand, which would exacerbate congestion.

Land Use

While mobility problems are most directly solved by transportation investment, land use plays a critical role in supporting the efficient movement of people and goods. In addition to using transit system investment to expand transportation network capacity, strategic land use planning that focuses higher-density, mixed-use development near transit stations can reduce demand on the

[2] *Paths to a Sustainable Region*, the current Long Range Transportation Plan for the Boston metropolitan region, adopted by the MPO on September 22, 2011

[3] *FY 2013-FY 2040 Regional Transportation Plan, Southern New Hampshire Planning Commission*, October 23, 2012

transportation network by supporting trip efficiencies. More efficient land use patterns can also result in employment opportunity expansion closer to home, which could reduce overall demand on the transportation network (because of shorter travel distances) and reduce overall travel times (shorter distances and reduced congestion).

Sustainability

Part of New Hampshire's character is its mountain ranges, chains of lakes, sea coast, and protected forest land. Increased levels of development and corresponding growth in transportation network demand may negatively impact these environmental assets.

The optimal transportation infrastructure network considers the interconnection between development patterns, availability of housing choices, and transportation diversity as a means to preserve natural resources and community vitality and promote energy efficiency.

Section 3: Financial Plan

Task Objective

Identifying stable and reliable funding sources is critical to advancing a transit alternative, as investing in an improved transit infrastructure incurs two types of costs:

1. **Capital Costs** – the up-front costs of implementing a new or enhanced transit system
2. **O&M Costs** – the annual costs incurred after the system is active

Since the pool of federal funding options is more robust than state and local options, leveraging available federal funds is a key objective of the Capitol Corridor Financial Plan.

Federal funds of most interest to cover capital costs are those considered "discretionary," i.e., funds not otherwise available to New Hampshire for other purposes; other types of federal dollars, "formula funds," are available to pay for O&M. Receipt of federal funds is subject to a variety of eligibility rules, and most federal funds must be "matched" (typically by 20 percent) by state and/or local funds. Given the match requirement, the Study team also identified potential state and local funding sources that could provide this match.

Capital and O&M Funding Needs by Alternative

For each of the seven intermediate alternatives (Section 5, Appendix 5), capital and O&M costs were estimated in 2014 dollars and 2012 dollars, respectively (Section 7, Appendix 7).

For the rail alternatives, a four-year construction period was assumed, beginning in 2019. Annual O&M costs for each alternative were also estimated based on costs for similar services provided elsewhere in New England or based on recent historic expenditures for similar services in New Hampshire.

Note that the cost figures contain substantial "contingency costs," which are added to actual cost estimates to reflect uncertainty regarding costs developed during early planning in any project. This is a standard procedure.

The No Build alternative is not shown in Figure 6, as this option does not incur capital costs and O&M costs remain unchanged.

Figure 6 – Final Capital and O&M Costs for the Seven Intermediate Alternatives

Alternative	Capital Costs (In Millions, 2014$)	Annual O&M Costs (In Millions, 2012$)
Manchester Regional Commuter Rail	$245.6	$10.8
Nashua Minimum Commuter Rail	$120.3	$4.1
Intercity 8	$256.5	$7.7
Expanded Base	$9.6	$3.0
Bus on Shoulder	$7.4	$0.0
Expanded Bus on Shoulder	$17.0	$3.0

Federal Funding Sources

Within USDOT, FTA administers the primary funding programs available for public transportation investments; FHWA administers some federal-aid highway programs with flexible provisions that allow transfer of funds for public transportation investments; and FRA administers the RRIF program, which can be used for passenger rail projects, and in the past has provided capital funding through the HSIPR program.

In addition, federal finance tools are available that can be used to advance project implementation by leveraging future revenue streams of dedicated funding.

Figure 7 is a high-level summary of these federal funding sources and tools, including potential eligibility for commuter rail, intercity rail, and intercity bus alternatives.

Figure 7 – Federal Funding Sources and Tools Summary

Funding Source/Tool	Capital, O&M or Both	Eligible Alternative
FTA 5311(f) Intercity Bus	Both	Intercity Bus
FTA 5309 CIG (New and Small Starts Program)	Capital	Commuter Rail
FTA 5307 Urbanized Area Formula Grants	Capital	Commuter Rail, Intercity Bus
FTA 5337 SGR Grants	Capital	Commuter Rail
FHWA NHPP	Capital	Intercity Bus
FHWA STP	Capital	Commuter Rail, Intercity Bus
FHWA CMAQ	Both	Commuter Rail, Intercity Rail, Intercity Bus
FRA HSIPR	Capital	Intercity Rail
USDOT TIGER	Capital	Commuter Rail, Intercity Rail
USDOT Transportation Infrastructure Finance and Innovation Act (TIFIA)	Capital	Intercity Rail, Commuter Rail, Intercity Bus
FRA RRIF	Capital	Intercity Rail, Commuter Rail

Non-Federal Funding Sources

As evident in Figure 7, federal funds typically contribute a large share of transit project capital costs. O&M costs are typically financed through state and local funding sources. Most state transit funding comes from General Fund appropriations or through traditional taxes and fees, such as motor fuel taxes, sales taxes, and vehicle fees. State transit funding provides both operating assistance and capital funds, but only a few states provide dedicated funding either for capital expenses (Arkansas, Idaho, Kentucky, and Nevada) or operating expenses (Maine, South Dakota, and Wisconsin). Local transit funding is primarily provided through General Fund allocations, dedicated local option taxes and fees (sales taxes, property taxes, motor fuel taxes, vehicle fees, employer/payroll taxes, utility taxes/fees, room/occupancy taxes) and value capture mechanisms (impact fees, Tax Increment Financing, special assessment districts, and joint development).

Figure 8 summarizes potential New Hampshire funding sources for a Capitol Corridor project, each of which is discussed in detail in Appendix 3, Financial Plan. For each option, a definition is provided, followed by an assessment of the feasibility and potential revenue estimate for each

source. Ratings for feasibility reflect an assessment of 1) whether the source currently exists in New Hampshire, 2) whether transit is an eligible expenditure for the funding source, 3) the extent of likely support for the source, and 4) actions (e.g., legislative) that would be required for use of the source as part of the project's financial plan to cover costs.

The amount of revenue that might be generated from each source also is estimated. All of these estimated yields are subject to change based on changes to input assumptions and charge rates. Annual yield rating ranges: estimates greater than $5 million = High; $1-$5 million = Medium; less than $1 million = Low.

Figure 8 – Summary of Non-Federal Funding Options for Capitol Corridor Alternatives

Funding Source	Feasibility	Yield	Annual Estimate (In Millions)	Comments
NH State Capital Program	High	High	$10.0	7.6% of 2014 debt payment (principal + interest)
NH Parking Fees	High	Low	$0.7	Based on $4.00 per day parking fee
Vehicle Registration Fees	Medium	High	$5.9	$5.00 fee on passenger vehicles and trucks statewide
Municipal Contribution	Medium	Medium	$1.0-3.0	$1 million/city with new stations; city discretion regarding source
Regional Greenhouse Gas Initiative (RGGI)	Medium	Low	$0.5	Based on historical awards
Property Tax	Low	High	$15.7	0.1 mill applied statewide
Lottery Revenues	Low	Medium	$3.7	5% of net proceeds
Passenger Facility Charges	Low	Medium	$1.0	½ of $1.50 passenger facility charge (PFC) increase beginning in 2016
Value Capture	Low	Low	--	Need more study to estimate

Funding Summary by Alternative

Figure 9 summarizes federal-funding potential for the three final rail alternatives.

None of the three intermediate bus alternatives require significant new capital investment (estimates for new buses and infrastructure improvements range from $9.6 million to $17.0 million); the capital required likely could be covered by federal formula programs such as Section 5307 or CMAQ. Other new revenue sources are unlikely, given the limited additional mobility and economic benefits anticipated by increasing or otherwise enhancing existing bus service.

Figure 9 – Federal Funding Potential for the Three Final Rail Alternatives

Final Alternative	Description
Manchester Regional Commuter Rail	Candidate for New Starts funding established under FTA's CIG program. Eligible New Starts projects that meet certain criteria receive on average 50 percent of their capital costs. The remaining costs could be covered by other federal funding programs, such as CMAQ, as well as parking revenue and contributions from MBTA (track work and trackage rights, rolling stock) and the municipalities that will have commuter rail stations (Nashua, Bedford (Manchester Airport station), and Manchester).
Nashua Minimum Commuter Rail	Candidate for Small Starts funding established under FTA's CIG program. Eligible Small Starts projects that meet certain criteria receive up to $75 million of their capital costs. The remaining costs could be covered by other federal funding programs, such as CMAQ and TIGER grants, as well as parking revenue and contributions from the MBTA (track work, rolling stock) and from Nashua.
Intercity 8	Will rely on federal programs, namely FRA's HSIPR. However, the HSIPR currently has no funding available. For purposes of this assessment, it is assumed that half the capital costs of the project might be paid for by a future HSIPR appropriation. Similar to the two commuter rail alternatives, local sources could include CMAQ, parking revenue, and contributions from the three municipalities with stations (Nashua, Manchester, and Concord).

Section 4: Initial Conceptual Transit Alternatives

Task Objective

Initial conceptual transit alternatives were developed to accomplish two objectives:

1. Address key transportation and related issues identified in the Study's purpose and need
2. Provide commuter bus (BX), commuter rail (MBTA), and intercity rail (possibly Amtrak) service and operating plans to accommodate FTA and FRA funding sources

Preliminary Costs for 12 Initial Alternatives

Six Commuter Rail Alternatives

- ✓ Capital costs range from $124 to $226 million
- ✓ Annual O&M costs range from $5.2 to $13.3 million

Three Intercity Rail Alternatives

- ✓ Capital costs range from $162 to $174 million
- ✓ Annual O&M costs range from $7.7 to $17.3 million

Three Express Bus Alternatives

- ✓ Capital costs range from $2.2 to $8.6 million
- ✓ Annual O&M costs range from $5.9 to $9 million

Preliminary Alternatives

Figure 10 shows all 12 initial alternatives (and the No Build option), their service levels, preliminary capital costs (including locomotives and passenger cars, track and signal improvements, and stations), and preliminary O&M costs.

Cost estimates included in Figure 9 were developed for *preliminary* evaluations. They were then refined based on additional engineering analysis, which explains differences between the preliminary estimates and later more detailed cost data – and will be refined again if a project moves forward. This is standard procedure in transit planning studies.

Figure 10 – Preliminary Capital and O&M Costs for the 12 Preliminary Alternatives (and No Build Option)

Alternative	Daily Service	Capital Cost (In Millions, 2014$)	Annual O&M Cost (In Millions, 2009$ Commuter Rail, 2012$ Intercity/Bus)
No Build	Status Quo - Total buses (inbound/outbound): Manchester 18, N. Londonderry (Exit 5) 46, Londonderry (Exit 4) 17, Salem (Exit 2) 39, Nashua (Exit 8) 24, Tyngsborough (Exit 35) 23, South Station 80, Logan Airport 58	$0	$5.9
Commuter Rail			
Concord Regional	8 trains (4 round trips) to Concord and Manchester 30 trains to Nashua	$226	$11.1
Concord Commuter	18 trains to Concord 22 trains to Manchester 26 trains to Nashua	$206	$13.3
Manchester Regional	16 trains to Manchester 34 trains to Nashua	$164	$9.7
Manchester Commuter	20 trains to Manchester 30 trains to Nashua	$164	$9.9
Nashua Commuter	34 trains to Nashua only	$124	$6.8
Nashua Minimum	16 trains to Nashua only	$124	$5.2
Intercity Rail			
Intercity 18	18 trains (9 round trips) to Nashua, Manchester, and Concord	$174	$17.3
Intercity 12	12 daily trains to Nashua, Manchester, and Concord	$174	$11.6
Intercity 8	8 trains to Nashua, Manchester, and Concord	$162	$7.7
Express Bus			
Expanded Base	Total buses (inbound/outbound): Manchester 32, N. Londonderry (Exit 5) 40, Londonderry (Exit 4) 39, Salem (Exit 2) 40, Nashua (Exit 8) 38, Tyngsborough (Exit 35) 38, South Station 120, Logan Airport 120	$6.4	$9
Bus on Shoulder	Total buses (inbound/outbound): Manchester 18, N. Londonderry (Exit 5) 46, Londonderry (Exit 4) 17, Salem (Exit 2) 39, Nashua (Exit 8) 24, Tyngsborough (Exit 35) 23, South Station 80, Logan Airport 58	$2.2	$5.9
Expanded Bus on Shoulder	Total buses (inbound/outbound): Manchester 32, N. Londonderry (Exit 5) 40, Londonderry (Exit 4) 39, Salem (Exit 2) 40, Nashua (Exit 8) 38, Tyngsborough (Exit 35) 38, South Station 120, Logan Airport 120	$8.6	$9

Developing Preliminary Capital and O&M Costs

Rail Alternatives: For each rail option (MBTA and Amtrak), conceptual schedules were designed, existing track configuration analyzed, and schematic track diagrams prepared. The Study team consulted an array of sources (e.g., Nashua Regional Planning Commission Passenger Rail Study), considered their experience working for and with the MBTA on passenger rail renewal projects, accounted for cost drivers and made educated assumptions (such as new track and number of tie replacements), and received feedback from MBTA and Amtrak. Costs for rolling stock were excluded from preliminary commuter rail estimates (MBTA indicated they would supply necessary rolling stock), but included in preliminary intercity rail estimates (Amtrak indicated they could not operate the new service from within their existing fleet). MBTA 2009 cost reports to FTA were used to estimate O&M cost drivers (increased train miles, increased rolling stock [locomotives and coaches], and increased track miles), and Amtrak officials were consulted for guidance predicting O&M costs based on their historical data.

Bus Alternatives: Preliminary estimates of capital costs for the bus options were driven by two factors:

1. Additional buses required to operate more frequent service
2. Roadway upgrades required to allow for Bus on Shoulder operations, which would provide more reliable peak service

The Study team consulted several sources (e.g., Merrimack Valley Planning Commission's 2014 Study on Bus Use of Shoulders); analyzed existing right-of-way conditions; met with NHDOT and BX officials; and made educated assumptions based on past experience in upgrading drainage, striping, and signage along the route.

O&M costs were estimated by developing weekday service schedules, including estimates of vehicle requirements and bus miles, and reviewing these schedules with BX; BX also provided service statistics and cost summaries.

Section 5: Preliminary Evaluation of Conceptual Alternatives and Recommended Alternatives for Detailed Evaluation

Task Objective

The 12 conceptual/preliminary alternatives were evaluated against six criteria:

1. Capital Costs
2. Ridership
3. Land Use and Economic Development Impacts
4. Environmental Fatal Flaws
5. Opportunity Cost (the financial savings from doing nothing, or relatively little, weighed against resulting opportunities lost)
6. Cost-Benefit Ratio (how successfully an alternative delivers greater benefits at a comparatively low cost)

Based on this evaluation, seven of the 12 alternatives were selected as candidates for detailed evaluation (see Section 7, Appendix 7).

Preliminary Evaluation Criteria

The Cost of Doing Nothing

In addition to studying the financial, economic, land use, and environmental costs of making a transit investment in the Capitol Corridor, this Study also evaluated environmental costs and costs to individuals, the broader population, and the economy that would result from *not* making a transit investment.

Costs and Ridership

Preliminary capital costs and ridership data (Figure 11) were collected to guide the early screening process. Capital costs for each alternative include construction, equipment, stations, track right-of-way and signal upgrades, and highway improvements (see Appendix 4, Preliminary Capital Cost Methodology Memo); ridership is defined as the average weekday ridership in terms of total boardings (see Appendix 6, Rail Ridership Forecast Methodology Memo).[4]

Figure 11 – Preliminary Capital Costs and Ridership Data

Alternative	Capital Cost (In Millions, 2014$)	Incremental Ridership (Total Weekday Boardings)
No Build/No Transit Improvement	$0	---
Concord Regional Rail	$226	2,700
Concord Commuter Rail	$206	3,020
Manchester Regional Commuter Rail	$164	3,120
Manchester Commuter Rail	$164	3,060
Nashua Commuter Rail	$124	2,040
Nashua Minimum Commuter Rail	$124	1,480
Intercity 8	$162	1,460
Intercity 12	$174	1,720
Intercity 18	$174	2,040
Expanded Base	$6	346
Bus on Shoulder	$2	692
Expanded Bus on Shoulder	$9	1,038

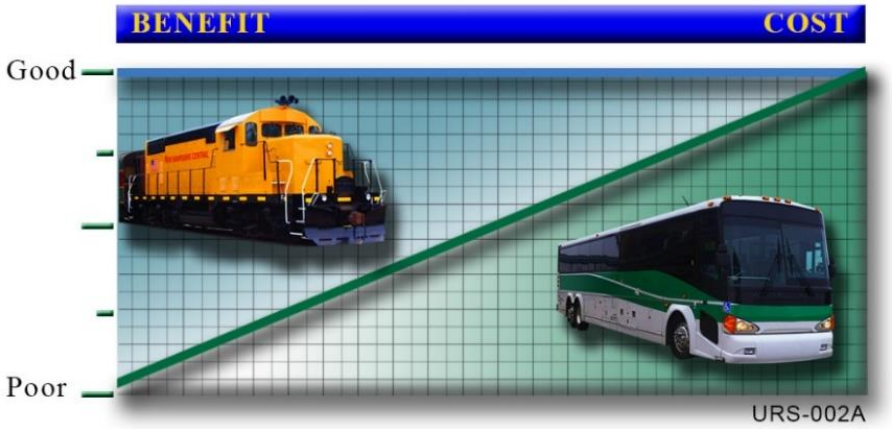
[4] Cost estimates for the preliminary alternatives were refined based on additional engineering analysis, which explains differences between the preliminary estimates and later more detailed cost data – and will be refined again if a project moves forward. This is standard procedure in transit planning studies.

Land Use and Economic Development Impacts

Because strategic land use planning that focuses higher-density, mixed-use development near transit stations can reduce demand on the transportation network and also result in employment opportunity expansion closer to home, the Study team considered how likely each alternative would help promote desirable TOD development patterns.

Cost-Benefit Ratio

In general, bus alternatives are far less expensive than rail projects. However, in transit planning, benefits often rise with costs, and this is certainly true with the rail-bus tradeoffs in the Capitol Corridor. While rail costs are significantly higher than those for bus-based strategies, the benefits resulting from rail are also considerably greater, especially regarding beneficial land use and TOD impacts.



Benefits rise as costs rise. The inverse is also true: low costs, low benefits

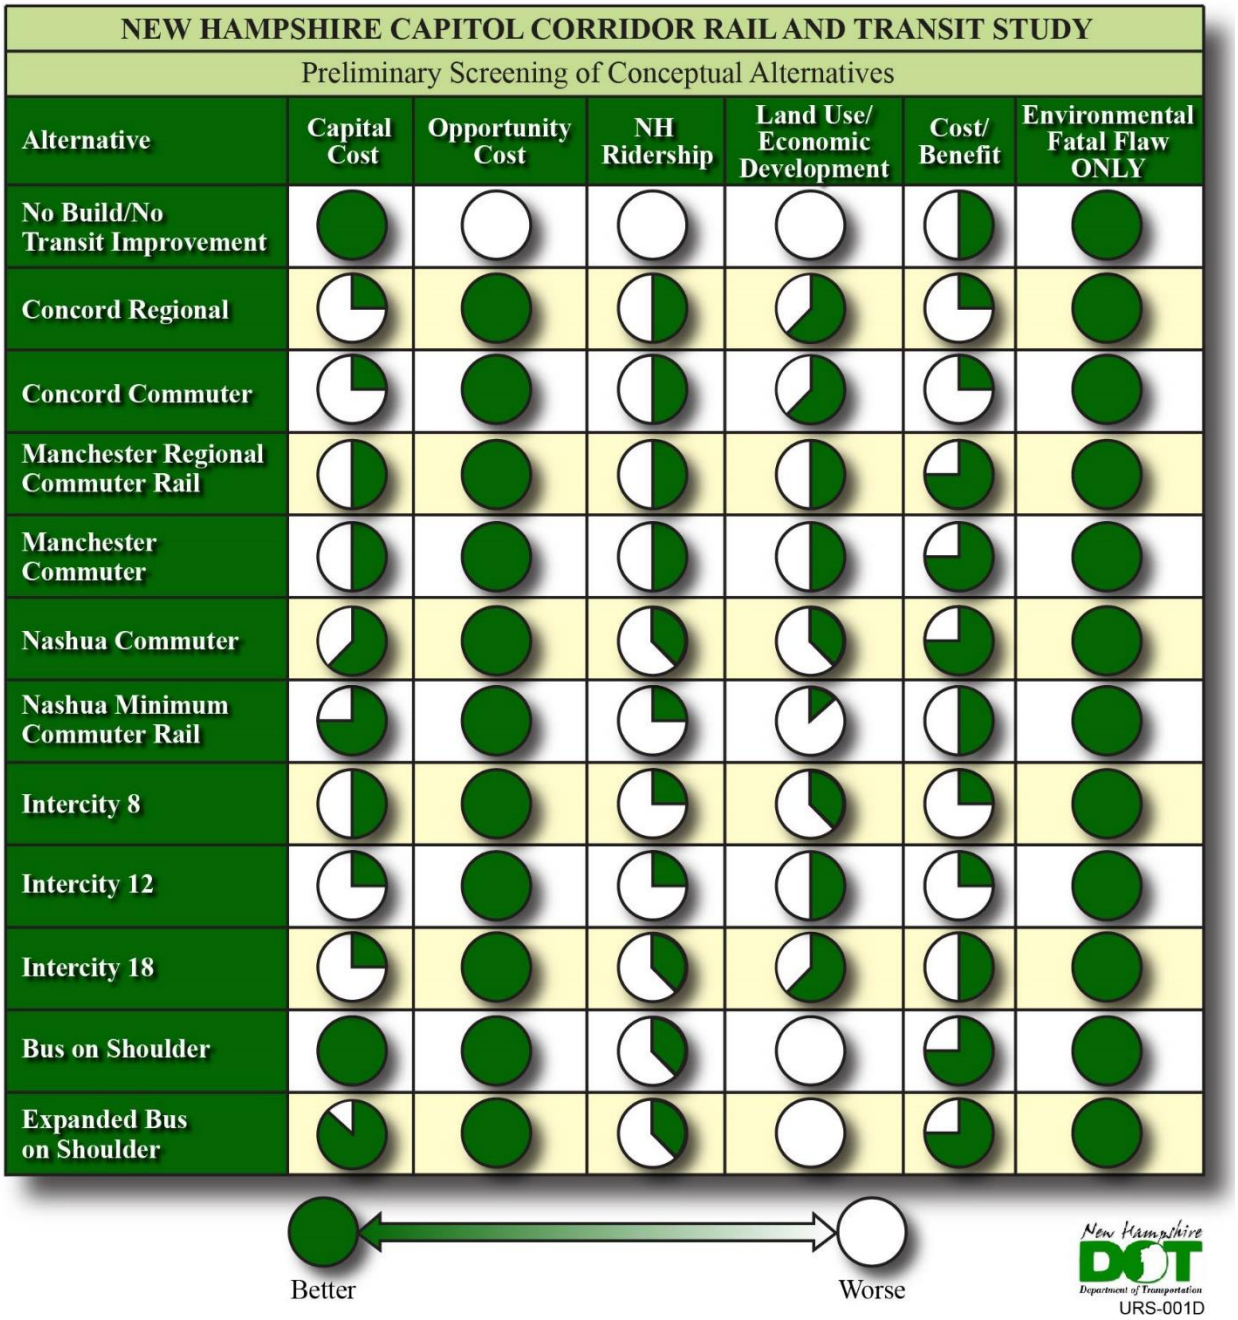
Environmental Fatal Flaws

While environmental impacts (positive and negative) are important, for the purposes of screening alternatives in this early Study phase, the Study team considered only major negative impacts and environmental fatal flaws – flaws that by themselves would disqualify alternatives. None were found.

Preliminary Evaluation Results

Figure 12 on the next page shows evaluation results. Each preliminary alternative received a qualitative rating from best (full circle) to worst (empty circle), or, in most cases, somewhere in between. Ratings (and therefore rankings) are *relative to the other alternatives in the Capitol Corridor Study – rather than to any national standards or projects in other regions around the country.*

Figure 12 – Preliminary Evaluation Results



Preliminary Evaluation Conclusions

This preliminary assessment, input from two public meetings in Manchester and Concord (the third public meeting presented final alternatives for further consideration), discussions with New Hampshire and Massachusetts stakeholders (Section 1, Appendix 1), and extensive consultation with FTA and FRA resulted in selection of seven intermediate alternatives to advance into more detailed analysis.

Figure 13 lists these seven intermediate alternatives and qualifies their selection.

Figure 13 – Rationale for Selecting the Seven Intermediate Alternatives

Selected Alternative	Description	Primary Reason for Selection
No Build	Existing bus service from Concord and Manchester to Boston via I-93 and Route 3	Lowest capital cost alternative
Manchester Regional Commuter Rail	Extension of MBTA Lowell line terminating in downtown Manchester; retains existing bus service on I-93 and Route 3	Most cost-effective initial option
Nashua Minimum Commuter Rail	Commuter rail service from a South Nashua terminus to North Station in Boston, an extension of the current MBTA Boston-Lowell line; retains existing bus service on I-93 between Concord and Manchester, and South Station and Logan Airport in Boston, and on Route 3	Lowest-cost rail alternative of initial 12 alternatives
Intercity 8	Intercity service from Concord to North Station added onto existing MBTA Lowell-Boston service, similar to the original Amtrak Boston-Portland *Downeaster* service; retains all existing bus service on I-93 and Route 3	Lowest cost of original intercity alternatives
Expanded Base	Additional service on existing system	Increases bus frequency and provides non-stop peak-period service
Bus on Shoulder	Existing bus service using I-93 shoulders in Massachusetts	Improves service reliability by bypassing congestion
Expanded Bus on Shoulder	Additional service using I-93 shoulders on I-93 in Massachusetts	Improves service reliability, increases bus service frequency, and provides non-stop peak-period service

Section 6: Evaluation Criteria and Methodology

Task Objective

To evaluate each of the seven intermediate alternatives, the Study team developed eight criteria:

1.	**Ridership**	What is the average weekday ridership for each alternative?
2.	**Costs (Capital and O&M)**	What is the cost to build and operate each alternative?
3.	**Land use impacts**	To what degree does an alternative result in relatively compact, environmentally sensitive development patterns?
4.	**Economic development impacts**	How does the alternative contribute to the economy of the corridor and region?
5.	**Equity and environmental justice**	What are the relative impacts of an alternative on lower-income and minority communities?
6.	**Environmental impacts**	How does the alternative affect the natural, social, and economic environments?
7.	**Financial feasibility**	What is the likelihood of developing a financial plan that will fund the construction and operation of the alternative?
8.	**Public support**	How strong is the support for the alternative, to the point of moving it into implementation, including the acceptance of a feasible financial plan?

These eight criteria were then grouped into broader categories – e.g., "financial considerations" includes costs (capital and O&M) and feasibility of a financial plan and public support of that plan.

Performance of each intermediate alternative against the detailed evaluation criteria is discussed in Section 7 and detailed in Appendix 7. Environmental impacts are further discussed in Section 10 and detailed in Appendices 10a and 10b.

Technical Methodologies

Four technical methodologies were used to produce data and other non-quantitative assessments of the seven intermediate alternatives' relative impacts:

1. Capital costs
2. O&M costs
3. Travel demand forecasting (ridership)
4. Equity

Ridership and equity are summarized here and in Appendix 6. Detail on final cost methodologies and estimates can be found in Section 7 and Appendix 7.

Travel Demand Forecasting (Ridership)

Rail ridership forecasts for the Manchester Regional and Nashua Minimum Commuter Rail alternatives were developed using existing MBTA commuter rail system data. Multiple models were estimated using rail operations data, station characteristics, socio-economic data, U.S. Census Transportation Planning Package journey-to-work (JTW) data, and available MBTA system boarding data.

The resultant daily ridership estimates are provided in Figure 14. The upper and lower bound are the 95 percent confidence interval around the forecast data.

Figure 14 – Daily Ridership Estimates for Intermediate Commuter Rail Alternatives

Alternative	Ridership	Lower Bound	Upper Bound
Manchester Regional Commuter Rail	3,130	2,350	4,170
Nashua Minimum Commuter Rail	1,170	890	1,540

Equity Methodology

USDOT has directed federal agencies, including FRA and FTA to "ensure that all federally funded transportation-related programs, policies, or activities having the potential to adversely affect human health or the environment involve a planning and programming process that explicitly considers the effects on minority populations and low-income populations." (http://www.fta.dot.gov/12347_2238.html)

This AA Study therefore includes a high-level assessment (environmental justice analysis) of each intermediate and final alternative's potential for disproportionally adverse impacts on households below the poverty line, minorities, and households living in affordable units, as well as mobility and access benefits conferred to these households by each alternative. The Study team used U.S. Census Five-Year American Community Survey (2007-2011) data, online research, and interviews with municipal officials to perform the analysis.

Results are detailed in Section 7 and Appendix 7.

Section 7: Detailed Alternatives Evaluation

Task Objective

In Task 7, the seven intermediate alternatives selected in Task 5 (Section 5, Appendix 5) were evaluated using criteria developed in Task 6 (Section 6, Appendix 6):[5]

1. Economic impacts
2. Land use, including environmental impacts
3. Equity impacts
4. Financial considerations, including costs and feasibility of a financial plan/public support of that plan
5. Mobility impacts, including ridership forecasts

These are summarized below (with the exception of ridership forecasts since the preliminary estimates did not change) and provided in detail in Appendix 7. Detailed technical memoranda supporting criteria application – ridership forecasting, O&M costs, capital costs, sustainable land use, and corridor and regional equity – are also provided in Appendix 7.

Economic Development Impacts

Economic Development Impact Evaluation Results:

- ✓ Rail – high potential for positive impact
- ✓ Bus – no potential for positive impact

The Study team's economic assessment of the seven intermediate alternatives examined two types of economic benefit:

1. The amount of new development that might occur locally around new station areas
2. The impact of this new development, plus the investment in new or upgraded transit infrastructure measured in terms of employment and economic output in the Capitol Corridor region

[5] The eight criteria in Task 6 were grouped into five broader categories

Results show benefits associated with the three rail alternatives (Manchester Regional Commuter Rail, Nashua Minimum Commuter Rail, and Intercity 8) – all of which provide new permanent infrastructure (stations) – and no benefits associated with bus alternatives as none involve new stations (see Figure 15).

Figure 15 – Economic Impact Results Summary

Alternative	Station Area Development		Employment Impacts		
	Commercial (sq. ft.)	Residential (sq. ft.)	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	1,898,000	3,600	230	3,390	1,730
Nashua Minimum Commuter Rail	930,000	1,100	80	850	380
Intercity 8	819,000	1,640	350	2,460	1,140
Bus on Shoulder	0	0	0	0	0
No Build	0	0	0	0	0

Land Use Evaluation Results:

✓ Rail – medium potential for positive impact

✓ Bus – low potential for positive impact

Land Use

Each alternative was also evaluated for its ability to support local land use goals:

- **Environmental Goals:**
  - Catalyze more compact, transit-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power)
  - Reduce reliance on cars for trips/errands

- **Social Goals:**
  - Expand mobility and transportation choices for all age groups
  - Support low-income households through increased access to jobs

- **Economic Goals:**
  - Create more opportunities for people to move efficiently from place-to-place and establish more connections to transportation services to increase access and mobility
  - Access and mobility also affect the economies of the places served by transportation at local and regional levels (attract employers to New Hampshire, attract and retain regional employers to New Hampshire and Boston, and provide improved residency location choices in New Hampshire for commuters to Boston)

The bus alternatives rate relatively low on all goal categories, as does the Nashua Minimum Commuter Rail alternative. The Manchester Regional Commuter Rail and Intercity 8 rate "medium," indicating that their potential to spur development, generate jobs, and improve mobility along the corridor is greater than that of the bus or Nashua Minimum Commuter Rail options.

Equity Impacts

Public transit investment supports broad improvements in mobility, but is a particularly critical tool in increasing the mobility of transit-reliant or dependent populations, including households below the poverty line, minorities, and households in affordable housing units. The Study team used U.S. Census data to calculate statistics related to income, race, and housing for households and individuals in Census Tracts within a half-mile of each of the seven alternatives. This data was also collected for the States of New Hampshire and Massachusetts and the U.S. for comparative purposes.

Results (Appendix 7) indicate that the rail alternatives offer comparatively higher levels of service and transit access to households below the poverty line, minorities, and households in affordable housing units with minimal adverse impacts. The equity of and access to the rail alternatives improves as transit service extends north from Nashua (to Manchester and/or Concord) because those alternatives (Manchester Regional Commuter Rail and Intercity 8) reach more of those three populations.

The bus alternatives would not adversely impact households below the poverty line, minorities, and households in affordable housing units, but also would not offer expanded access to these populations through new station locations.

Final Capital and O&M Cost Estimates

As discussed in Section 4, the Study team consulted a variety of sources to estimate capital costs for each of the 12 alternatives. In estimating capital costs for the seven intermediate alternatives, detailed analysis led to a few changes. Here are two examples:

Financial Evaluation Results:

- ✓ Rail – final capital costs range from $120.3-$256.5 million, incremental O&M from $4.1 to $10.8 million
- ✓ Bus – final capital costs range from $7.4-$17 million, incremental O&M from $0-$3 million

1. During preliminary screening, it was assumed that the costs for developing commuter stations in Nashua, Manchester, and Concord would be local municipal expenses – so they were excluded from the project costs for screening purposes. This assumption was reversed in developing final cost estimates based on feedback from stakeholders and elected officials. While funding support for stations may be sought from municipalities, it was decided at this point that total project costs should be accounted for in the final cost estimates.
2. For the bus options, an allowance of $100,000 per route mile was included for upgrades to drainage, striping, and signage required for each of the 22 affected route miles; that estimate was revised to $250,000 per route mile for final screening based on unit costs encountered by the large Bus on Shoulder network in Minnesota and reported in a Transportation Research Board Transit Cooperative Research Program (TCRP) report from 2012.[6]

[6] Martin, Peter C. and Levinson, Herbert S.; *TCRP Report 151: A Guide for Implementing Bus On Shoulder (BOS) Systems*; Transportation Research Board; 2012

Figure 16 shows the final capital and O&M incremental cost estimates for each of the seven intermediate alternatives. Figure 17 provides a more detailed breakdown of capital costs for the three final rail alternatives. See Appendix 7, Final Capital Costs Methodology and Results and Final O&M Costs Methodology and Results, for detail.

Figure 16 – Final Capital and O&M Cost Estimates for the Seven Intermediate Alternatives

Intermediate Alternatives	Capital Cost (In Millions, 2014$)	Annual Incremental O&M Costs (In Millions, 2012$)
Manchester Regional Commuter Rail	$245.6	$10.8
Nashua Minimum Commuter Rail	$120.3	$4.1
Intercity 8	$256.5	$7.7
No Build	$0	$5.9
Expanded Base	$9.6	$3
Bus on Shoulder	$7.4	$0
Expanded Bus on Shoulder	$17	$3

Figure 17 – Detailed Breakdown of Capital Costs for the Three Final Rail Alternatives

	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Railway and Signal Improvements	$69.2	$31.7	$96.3
Bridges	$10.7	$2.1	$15.4
Stations	$20.8	$6.3	$18.7
Layover Yards	$12.4	$13.4	$4.8
Direct Construction Expense Subtotal	**$113.3**	**$53.7**	**$135.2**
Construction Allowances and Railroad Staff Support	$24.9	$11.8	$30.0
Land including Assemblage	$5.9	$7.8	$7.5
Contingency (35%)	**$50.0**	**$25.6**	**$60.5**
Rolling Stock	$33.2	$20.5	$23.3
Trackage Rights	$18.0	$0.9	$0.0
Total Project Value	**$245.6**	**$120.3**	**$256.5**

Section 8: Identification of the Recommended Strategy

Task Objective

The logical, sequential, analytical selection process (from Tasks 4 through 7) culminated in identification of a recommended transit strategy. While the term Locally Preferred Alternative (LPA) is commonly used to describe a recommended transit strategy resulting from an alternatives analysis such as the Capitol Corridor Study, it is probably more accurate to describe the recommended course-of-action as a comprehensive locally selected transit or intercity rail investment strategy, consisting of discrete investments, that may be implemented over a defined period of time.

In Task 8, the Study team identified factors most important in selecting the preferred strategy – the major differentiators – and described this strategy in detail (see Appendix 8).

Key Evaluation Criteria: Major Differentiators

Results of the comparative analysis conducted on the seven intermediate alternatives are shown in Figure 18, where the vertical axis shows the alternatives and the horizontal axis shows key evaluation criteria – the factors most important in drawing critical differences among alternatives or, in some cases, among sets of alternatives.

The final four columns in Figure 18 summarize the relative performance of the alternatives against four important evaluation criteria: new New Hampshire transit riders, costs (capital and O&M), land use impacts, and economic development potential. They reflect relative performance in that the alternatives are judged against each other, not by any national standard. A full circle indicates very strong performance and an empty circle very weak performance, with gradations reflecting intermediate performance; the darker a circle, the stronger an alternative is within that evaluation criterion.

Figure 18 – Comparative Analysis Summary

NH Capitol Corridor Rail and Transit Study

Alternative	New NH Transit Passenger Trips	Economic Benefits - Residential Units	Economic Benefits - Jobs	Total Capital Cost (In Millions, 2014$)	NH Costs after Federal Grants and MA Contribution	Annual Operating Cost (In Millions, 2012$)	Net Operating Cost (In Millions, 2012$)	Annual NH Debt Service (20 Year Bond)	Annual NH Total Cost (Debt Service and Operating Deficit)	Annual NH Cost per New Rider	Ridership New Riders	Cost Capital/ O&M	Land Use	Economic Development
No Build	0	0	0	$0	$0	$6	$1	$0	$1	$0				
Manchester Regional Commuter Rail	2,568	3,600	5,600	$246	$72	$11	$1	$6	$7	$10

URS-004G

Results – A Recommended Corridor Investment Strategy

Based on the analysis above, the Study team recommended narrowing the range of options from seven to five: No Build, Manchester Regional Commuter Rail, Nashua Minimum Commuter Rail, Intercity 8, and Bus on Shoulder operation for existing intercity bus service on I-93 in Massachusetts.

The rationale for selecting the recommended alternatives is summarized in Figure 19.

Figure 19 – Alternatives Recommended for Further Analysis

Alternative	Rationale for Selection
No Build	The maintenance of the status quo, including existing intercity bus service, is the lowest-cost (in terms of new investment dollars) alternative of all those considered.
Manchester Regional Commuter Rail	Considering the complete range of benefits, this option is the strongest alternative: Manchester Regional performs very well in terms of ridership, economic development, and land-use impact; however, it is one of the most expensive options.
Nashua Minimum Commuter Rail	The lowest-cost commuter rail option: while it does not stand out in terms of ridership and economic or land-use impacts, Nashua Minimum could serve as the first phase of Manchester Regional Commuter Rail service implementation.
Intercity 8	The lowest-cost intercity rail option; if implemented, Intercity 8 could serve as the first phase of more robust service similar to the original Amtrak Portland-Boston *Downeaster* service. As a relatively expensive alternative, Intercity 8 would require federal support for capital costs; while there is currently no source for such funds, if that situation changes, then Intercity 8 may be feasible.
Bus on Shoulder	Low on cost, low on benefits, and dependent on a decision by Massachusetts – as construction of any required Bus on Shoulder lanes on I-93 would be close to Boston. The possibility of New Hampshire financial support and reducing existing bus service if rail is implemented should be part of future policy discussions.

Section 9: Service Development Plan

Task Objective

Service development planning is the technical analysis of new passenger rail (and related public transportation) services by progressively narrowing the set of reasonable alternatives that can best meet Capitol Corridor needs. The SDP is required by the FRA, and, therefore, for this Study applies only to intercity rail options, FRA's focus in the Study. FRA must approve the SDP, which responds to the FRA's[7] desire to identify and implement corridor projects and programs that will achieve four results:

1. Serve as a catalyst for growth in regional economic productivity and expansion by stimulating domestic manufacturing, promoting local tourism, and driving commercial and residential development
2. Increase mobility by creating new choices for travelers
3. Reduce national dependence on oil
4. Foster livable urban and rural communities

The SDP lays out the overall scope and approach for the recommended intercity rail alternative, and accomplishes four objectives:

1. Clearly demonstrate the rationale for new or improved passenger rail service
2. Summarize analysis of the proposed new or improved passenger rail service and describe the alternative that would best address project rationale and purpose and need
3. Demonstrate the operational and financial feasibility of the new service
4. As applicable, describe how SDP implementation may be divided into discrete phases

[7] As noted earlier in *Project Organization and Funding*, this Capitol Corridor AA Study was jointly funded by FTA and FRA to ensure the broadest possible set of alternatives was considered to address the corridor's transportation issues.

Capitol Corridor Intercity Service Design and Operations Overview

Peak-period highway congestion slows Boston-bound travel to a 12 mph crawl for the final eight miles of a typical morning trip into the city.

The most salient transit problem addressed in developing the alternatives was improving connections between Southern New Hampshire and the regional core in downtown Boston. The principal travel obstacle in the corridor is the extreme peak-period highway congestion that slows Boston-bound travel to a 12 mph crawl for the final eight miles of a typical morning peak trip into the city.

The Study team consulted with MBTA, PAR, NHDOT, Massachusetts Department of Transportation (MassDOT), BX, Amtrak, and others to develop 12 service options for preliminary screening (see Sections 4 and 5, and Appendices 4 and 5) and narrowed those to seven intermediate options for refinement and more detailed analysis (see Sections 6 and 7, and Appendices 6 and 7).

Based on market analyses, ridership forecasts using FTA's Aggregate Rail Ridership Forecasting Model 2.0 (ARRF2), capital and O&M cost estimates, and other factors, Intercity 8 was selected as the recommended FRA alternative and the Manchester and Nashua Commuter Rail options as alternatives best suited to meet FTA requirements.

For the FRA Intercity 8 final ridership forecast, a separate, more refined forecast was prepared in collaboration with Amtrak and its ridership forecasting consultant, which has been supporting Amtrak's Market Research & Analysis Department with ridership and ticket revenue forecasts for all of Amtrak's services across the U.S. For Study purposes, Amtrak estimated ridership on the Intercity 8 service by analogy to the nearby 114 mile 10-train-per-day *Downeaster* service. Each station on the proposed Intercity 8 service was associated with a *Downeaster* "surrogate" station with similar travel time, station demographics, and train service characteristics. The model was then factored for differences between the surrogate *Downeaster* station and the proposed Capitol Corridor station.

In the SDP, the Study team describes the Intercity 8 service design, including stations and layover facilities, and provides an operations' overview; these are summarized below, with detail provided in Appendix 9.

Intercity 8 Design Summary

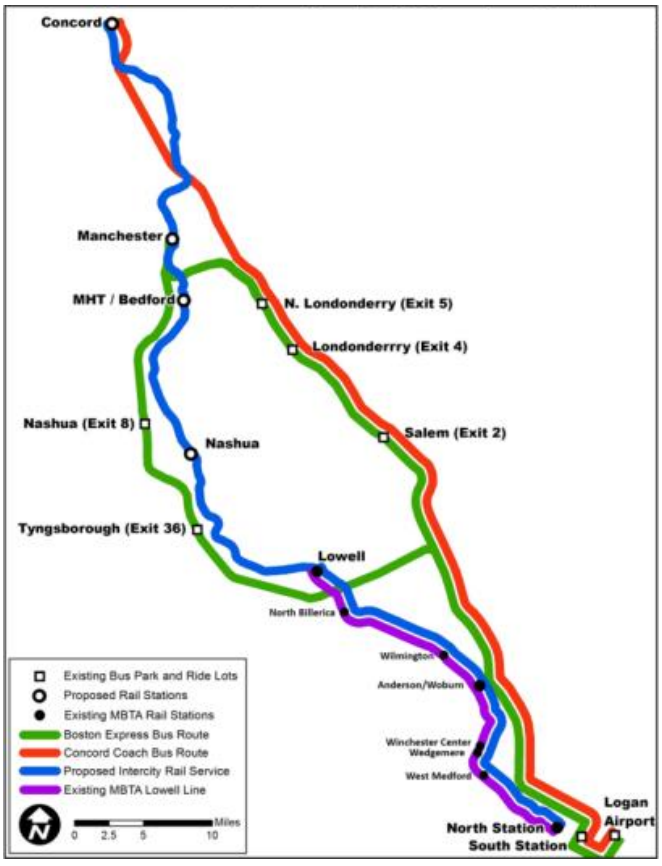
In designing the Intercity 8 option, the Study team worked to maximize the service frequency that could be offered effectively with a single set of equipment and limited crews serving the five major population centers along the corridor: Concord, Manchester, and Nashua in New Hampshire and Lowell and Boston in Massachusetts.

The design also provides service to the suburban Massachusetts intermodal hub in Woburn served by intercity passenger rail service between Portland, Maine and Boston (Amtrak *Downeaster*). The operating characteristics of the successful *Downeaster* service were influential to the Intercity 8 design. Both services (the *Downeaster* and the potential Intercity 8 service) would offer arrivals and departures at North Station at similar times of day.

Design details are summarized as follows:

- Eight trains per day or four daily round trips over the 73-mile route, stopping at five intermediate stations: Manchester, Bedford/Manchester Airport, Nashua, Lowell, and Woburn (Figure 20)
- End-to-end trip time would be approximately 96 minutes
- 586 daily train miles at maximum speeds of 75 mph between Bedford/Manchester Airport and Nashua and 70 mph at many other locations
- Expected to attract 172,645 passengers per year
- Presuming an average cost of $36 per train mile based on recent experience of the Amtrak *Downeaster* service, Intercity 8 would cost approximately $7.7 million per year to operate

Figure 20 – Intercity 8 Service Route



Service could be extended with possible connections to private bus services for North Country destinations. No changes are proposed to express bus service for commuting to Boston via I-93 or Route 3. Local bus service to the intercity rail stations could be offered, but would not be integral to the Intercity 8 service design. A BX/Concord Coach/rail fare integration scheme similar to that employed by the *Downeaster* at Portland, Maine could be employed at the Concord and Manchester stations that would be shared by both intercity rail and coach bus services.

Intercity 8 Operations Overview

For Study purposes, several presumptions were made regarding Intercity 8 operations:

- Operated by Amtrak, although no decision on the operator has been made at this point
- Offered with a single push-pull locomotive hauled train set with four coaches
- Rolling stock would be similar in configuration and performance to the equipment used for the *Downeaster* and MBTA commuter rail service; the train set would be stored and serviced overnight at the Concord Station where a plug-in and basic cleaning and servicing facility would be provided
- Operated from the same pool of equipment used to provide *Downeaster* service with an extra locomotive and control coach added to that pool to offset the additional burden this service would create; Amtrak would provide heavy maintenance at its facilities in Boston's Southampton Street Yard or further south on the Northeast Corridor as is the practice with the *Downeaster* equipment
- Two crews would be required to provide service each day, and a full roster of three crews plus a spare would be necessary to handle routine service requirements; the minimum required crew would be an engineer and conductor, although it is likely that Amtrak would operate the service with a third crew member to assist with operation of doors and management of passengers

Following detailed assessments and evaluations using criteria like market, access, track operational characteristics, land ownership, sensitive receptors, and environmental impacts, four stations (from eight evaluated) and one layover facility (from three evaluated) were recommended for the Intercity 8 service (Figure 21):

- Stations at Crown Street in Nashua, the Manchester Airport site below Ray Wieczorek Drive, Granite Street in Manchester, and Stickney Avenue in Concord
- Layover Facility at the Stickney Avenue site, close to the existing intercity bus terminal

Figure 21 – Intercity 8 Stations (from left to right: Crown Street, Nashua; Bedford/Manchester Airport; Granite Street, Manchester; and Stickney Avenue, Concord)

Intercity 8 Capital Costs and Benefits

The Intercity 8 service option is projected to cost $172.7 million for infrastructure and land, plus a $60.5 million contingency allowance and $23.3 million for the purchase of rolling stock that would be NHDOT's responsibility – for a total of $256.5 million. These costs are 2014 dollars.

Constructing and operating Intercity 8 in the Capitol Corridor would provide several benefits:

- **Reduced Vehicle Miles Travelled (VMT)** on the corridor's limited access highways by 44,794 results in reduced congestion and improved air quality
- **Station area benefits** stimulate and support sustainable land use patterns (TOD)
- **Economic development benefits resulting from rail service construction and operation**: 350 new jobs over the construction period (2019-2022), 2,460 jobs related to new real estate development between 2021 and 2030, and 1,140 new jobs annually in

2030 and beyond (with benefits beginning to accrue after 2021) due to reinvested worker earnings

- **Economic development benefits resulting from real estate development**: new real estate development is projected to add $750 million to New Hampshire's output between 2021 and 2030, with reinvested earnings adding $140 million per year beyond 2030
- **Increased service to and resulting positive equity impacts** on New Hampshire low income and minority populations
- **Freight service benefits**: with a passenger rail service on the line, the cost of providing existing freight service would be somewhat reduced

Section 10: Environmental Assessment

Task Objective

Two EAs were conducted:

- One for the **intercity rail investment strategy** (Intercity 8) to satisfy FRA requirements (Task 10a, Appendix 10a)
- The other for the **commuter rail investment strategy** (Manchester Regional Commuter Rail) to satisfy FTA requirements (Task 10b, Appendix 10b)

The environmental impacts examined in the Manchester Regional Commuter Rail EA cover each of the other final alternatives, Nashua Minimum Commuter Rail and Bus on Shoulder, as well. The focus in the EA on Manchester Regional Commuter Rail is for analytical purposes only, and that alternative should not be seen as the preferred investment, as extended debate and discussion is needed before a decision on an investment is made.

Both EAs follow the Service-level NEPA process to "typically address the broader questions relating to the type of service(s) being proposed, including cities and stations served, route alternatives, service levels, types of operations (speed, electric, or diesel powered, etc.), ridership projections, and major infrastructure components." Regardless of which investment strategy advances, additional analysis (either an EIS, EA, or CE, depending on project details and the significance of the impact) will need to be performed.

Figure 22 identifies potential environmental, social, and economic impacts associated with the transit investment strategies Intercity 8 and Manchester Regional Commuter Rail and summarizes appropriate mitigation measures. Differences in impacts are noted in gray shading; mitigation measures are the same for all impacts across both alternatives. As both EAs are Service-level NEPA documents, some resources will not have mitigation determined at this level of analysis.

Figure 22 – Summary of Resource Impacts and Proposed Mitigation for Intercity 8 and Manchester Regional Commuter Rail Transit Strategies

Resource	Intercity 8 Impact	Manchester Regional Commuter Rail Impact	Mitigation
Air Quality	Improved air quality through vehicle trips shifting to intercity rail		A number of sustainable mitigation measures can be implemented to improve air quality
Noise and Vibration	707 moderate noise impacts and 75 severe impacts due to warning horns; four potential daytime construction impacts and up to 324 potential nighttime construction impacts have been identified as a result of the analysis conducted pursuant to FTA guidelines; no vibration impacts expected	453 moderate noise impacts and 630 severe impacts due to warning horns; four potential daytime construction impacts and up to 309 potential nighttime construction impacts have been identified as a result of the analysis conducted pursuant to the FTA guidelines; possible vibration impacts dependent on schedule	Mitigation measures applied for each impact during the next phase of study
Hazardous Waste Sites	Short-term adverse impacts may occur during construction of rail and station sites due to potential for movement of contaminated soils or material		Phase I Environmental Site Assessments (ESAs) should be completed for each property acquired to be eligible for Landowner Liability Protections
Water Quality	Negligible to minor, short-term, localized impacts during construction activities		All impacts will be mitigated through Best Management Practices, including improvements to drainage and stormwater management
Wetlands	No impact to wetlands in most areas of the corridor and minor temporary and permanent impacts to jurisdictional wetland resource areas in a few discrete areas of the corridor ▪ Bedford/Manchester Airport – Ray Wieczorek Drive station has several wetlands and watercourses ▪ North of Ray Wieczorek Drive, the majority of the site is forested wetland ▪ South of Ray Wieczorek Drive, there are two small forested wetlands and one emergent/scrub-shrub wetland Minor temporary impacts may occur during construction activities		As more detail is developed in next phase, these impacts will be defined in greater detail; any wetland impacts would be subject to state and federal permitting requirements
Threatened and Endangered Species	None		Neither state agency has ruled on whether the project would qualify as a "take" under the regulations (to be confirmed in future analysis)

Resource	Intercity 8 Impact	Manchester Regional Commuter Rail Impact	Mitigation
Floodplains	Minor to negligible impacts to floodplains		In locations where floodplain elevations will be altered, the project will be provided compensatory floodplain storage; through mitigation, adverse impacts to floodplains will be kept to a minimum
Energy Resources	Beneficial impact: Diverting trips from vehicles to passenger rail will reduce overall VMT and greenhouse emissions; during construction, the project would consume energy through the processing of materials and construction activities		All impacts during construction will be addressed in the next level of analysis
Visual Resources	For work associated with the rail line, no impacts; for work associated with the stations and layover facility, negligible impacts	For work associated with the rail line, no impacts as the rail right-of-way historically accommodated double tracking throughout the length of the corridor; for the work associated with the stations and layover facility, negligible impacts	All mitigation measures associated with visual resource impacts will be addressed in the next level of analysis
Accessibility	None		None
Property Acquisition	Minor impacts: Station development would require acquisition of two privately held parcels		All mitigation measures associated with property acquisitions will be addressed in the next level of analysis
Land Use	Moderate beneficial impacts associated with increasing transit supportive development around stations, improving access to jobs, reducing the reliance on vehicles for trips, attracting employers to New Hampshire, retaining and attracting employers from New Hampshire to Boston, and improving residency location choice in New Hampshire for commuters to Boston or regional jobs		None
Environmental Justice (EJ)	Major beneficial impacts for those EJ populations within proximity to proposed stations in Concord, Manchester, and Nashua, as the project provides increased access to transportation options within the corridor	Major beneficial impacts for those EJ populations within proximity to proposed stations in Manchester and Nashua, as the project provides increased access to transportation options within the corridor	None
Public Safety	Beneficial impact through mitigation and upgraded safety features		A number of mitigation measures are recommended to improve the safety of 35 at-grade crossings for Intercity 8 and 22 for Manchester Regional Commuter Rail: upgrade the Centralized Traffic Control signal system; install all new equipment for the Automatic Highway Crossing Warning Systems; and it is assumed that Positive Train Control will be in place by the time route is operational

Resource	Intercity 8 Impact	Manchester Regional Commuter Rail Impact	Mitigation
Cultural Resources	No impact on Historic Architectural Resources; minor to negligible impacts to Archeological Resources		As the area's archeological potential is generally high, precautions will be put in place to mitigate adverse impacts
Park and Recreations	Unknown impact on Section 4(f) Resources in the corridor at Service-level of analysis		To be determined in future analysis
Socio-economics	Beneficial impact on New Hampshire economics by potentially generating the following: ▪ 1,600 new residential units ▪ 819,000 sq. ft. of commercial space ▪ 2,480 new station area jobs in 2030 and beyond, plus 1,100 other new jobs due to expansion of the economy ▪ 350 new jobs over the construction period (2019-2022) and 2,460 jobs related to new real estate development between 2021 and 2030 ▪ Real estate development would add $750 million to New Hampshire's output between 2021 and 2030	Beneficial impact on New Hampshire economics by potentially generating the following: ▪ 3,600 new residential units ▪ 1,898,000 sq. ft. of commercial space ▪ 5,600 new station area jobs in 2030 and beyond ▪ 230 new jobs over the construction period (2019-2022) and 3,390 jobs related to new real estate development between 2021 and 2030 ▪ Real estate development would add $750 million to New Hampshire's output between 2021 and 2030	None
Transportation	Beneficial impact on rail options and mobility by increasing transportation options		None
Indirect Effects and Cumulative Impacts	Indirect Effects: Beneficial long-term effects due to induced growth and development around station locations; Cumulative Impacts: Incremental beneficial impact through greater access to transportation options and reduction in VMT within Route 3 and I-93 corridor

1 Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs shared transportation accommodations that support "car-light" mobility
- Growing residential development patterns may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels-of-demand without negative environmental consequences

2 Task Objectives

A Public and Stakeholder Involvement Plan (PSIP) was developed that outlines how the New Hampshire Department of Transportation (NHDOT) – in cooperation with Federal Railroad Administration (FRA), Federal Transit Administration (FTA), and the Study team – would both educate and seek input from private entities, public agencies, communities, residents, and the traveling public. The PSIP's purpose was to describe how stakeholder and public input would be sought to inform the completion of key project milestones, including the definition of the Study Purpose and Need, the development of alternatives, the evaluation of alternatives, the selection of a recommended strategy, and the methods by which clear and understandable information would be developed and disseminated at the conclusion of each Study milestone. Activities described in this plan would educate key stakeholders and the public

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

about the technical analyses that fed into the decision-making process and to receive input for that process.

A variety of approaches were used to inform stakeholders of Study activities and there were numerous opportunities for discussion and comment. Public opinion and comments were documented and considered throughout the process. The main objectives of the public and stakeholder outreach activities for the Capitol Corridor AA Study are as follows:

- Build support for the AA Study and service development planning process among different stakeholder groups
- Encourage stakeholders to engage in the development process
- Provide clear and understandable information at each step of the process
- Document public and stakeholder opinion as part of the decision-making process
- Create a high-level of transparency regarding how the project is conducted

Because the Study included rail transit service as an alternative in the State of New Hampshire, the Study attracted significant interest from public and private stakeholders throughout the region, as well as members of the general public. Public and stakeholder outreach began at Study initiation and was proactive, consistent, and timely to fully engage the public and key stakeholders in the process. Federal, state, and local agencies with regulatory authority were contacted throughout the process to provide input and comment. In addition, NHDOT identified quasi- and non-governmental stakeholders, and solicited comments through public information meetings, Project Advisory Committee (PAC) meetings, a project website, and other activities.

3 Agency and Stakeholder Coordination

The Study team and NHDOT conducted 91 stakeholder meetings, three PAC meetings, and three public meetings (in Concord, Manchester, and Nashua) over the Study's 21-month lifecycle. The initial phase of stakeholder engagement was designed to solicit input from a broad, diverse range of players who all have a stake in the future of passenger rail in New Hampshire.

3.1 Project Advisory Committee (PAC)

The PAC provided input to the Study, including the vetting of early, preliminary alternatives. Throughout the Study, the PAC held meetings (including ongoing Study progress discussions) that coincided with the conclusion of major Study milestones and phases. The Study team coordinated the PAC's efforts. In addition, the Governor's Office, Congressional Delegation Offices, Executive Councilors, and State Senators and State Representatives from communities along the Capitol Corridor were notified of all meetings (public meetings and PAC meetings). Information on the PAC meetings is provided in Appendices 10a and 10b to the AA Final Report.

The following organizations were PAC members:

- Amtrak
- Central New Hampshire Regional Planning Commission
- City of Concord, New Hampshire
- City of Manchester, New Hampshire
- City of Nashua, New Hampshire/Nashua Transit System
- Conservation Law Foundation of New Hampshire
- The Greater Concord Chamber of Commerce
- The Greater Nashua Chamber of Commerce
- Lowell Regional Transit Authority
- Manchester Transit Authority
- Manchester-Boston Regional Airport
- Massachusetts Bay Transportation Authority
- Massachusetts Department of Transportation
- Merrimack Valley Planning Commission
- Nashua Regional Planning Commission
- New Hampshire Rail Transit Authority
- Northern Middlesex Council of Governments
- Pan Am Railways
- Rockingham Planning Commission
- Southern New Hampshire Planning Commission

3.2 Other Stakeholders

One-on-one interviews and group briefings were held early in the Study with representatives of stakeholder groups identified by the Study team in consultation with NHDOT. These sessions allowed NHDOT and the Study team to convey information about the Study' scope and process and gain an understanding of stakeholders' perceptions of the Study, sensitivities associated with the project, and how local communities might react to the project. Stakeholders also provided information on other individuals and organizations that might have a particular interest in or provide support for the project.

Following is a list of stakeholders and a brief description of each.

- Anagnost Companies: Manchester developer
- C&J Trailways: Regional bus service provider in the Study area
- Central New Hampshire Regional Planning Commission (RPC): Planning commission serving 20 communities in Central New Hampshire, including the City of Concord

- City of Concord, New Hampshire
- City of Dover, New Hampshire
- City of Manchester, New Hampshire – Board of Aldermen: Legislative body of the City of Manchester
- City of Manchester, New Hampshire – Mayor's Office: Executive Office of the City of Manchester
- City of Nashua, New Hampshire/Nashua Transit System: Second largest city in New Hampshire; both Route 3 and existing rail line runs through the city
- Concord Area Transit: Public transit provider in the City of Concord
- Greater Concord Chamber of Commerce: Business advocacy organization representing businesses in the Central New Hampshire region
- Concord Coach/Dartmouth Coach/Boston Express: Regional bus service providers in the Study area
- Conservation Law Foundation: Non-profit focusing on environmental issues in New England
- FRA: Grantee for the portion of the Study to develop a Service Development Plan and related documents for intercity passenger rail service in the corridor between Boston and Concord
- FTA: Grantee for the portion of the Study to provide an AA for transit service in the Concord-Boston corridor
- Mount Washington College, Manchester, New Hampshire
- Lowell Regional Transit Authority: Public transit provider in the greater Lowell region
- Greater Manchester Chamber of Commerce: Business advocacy organization representing businesses in the Manchester region
- Manchester Community College, Manchester, New Hampshire
- Manchester Transit Authority: Public transit provider in the greater Manchester region
- Manchester-Boston Regional Airport (Manchester Airport): Public airport located in Manchester, New Hampshire
- Massachusetts Department of Transportation (MassDOT)/Massachusetts Bay Transportation Authority (MBTA): MassDOT is the state agency that coordinates, plans, and funds all public transportation infrastructure within the Commonwealth; MassDOT oversees the MBTA, which is responsible for providing public transit service to 176 cities and towns in Massachusetts
- Massachusetts Historical Commission: Established in 1963 to identify, evaluate, and protect important historical and archaeological assets of the Commonwealth
- Merrimack Chamber of Commerce: Business advocacy organization representing businesses in the Merrimack region
- Merrimack Valley Planning Commission: Regional planning agency serving 15 communities in the northeast region of Massachusetts
- Greater Nashua Chamber of Commerce: Business advocacy organization representing businesses in the Southern New Hampshire region

- Nashua RPC: Planning commission serving 13 communities in Southern New Hampshire, including the City of Nashua
- National Railroad Passenger Corporation (Amtrak): Publicly-supported service that operates intercity passenger rail service throughout the U.S.
- New Hampshire Rail Transit Authority (NHRTA): Established by the legislature in 2007 for the general purpose of developing and providing commuter rail or other similar forms of passenger rail service; the authority is administratively attached to NHDOT
- New Hampshire Technical Institute, Concord, New Hampshire
- New Hampshire Congressional Delegates: Senators Jeanne Shaheen and Kelly Ayotte; Representatives Carol Shea-Porter and Annie Kuster
- New Hampshire Department of Environmental Services (NHDES): State agency concerned with the protection and wise management of New Hampshire's environment
- New Hampshire Department of Resources and Economic Development (NHDRED): State agency concerned with economic development in the State of New Hampshire
- New Hampshire Division of Historical Resources: Established as the State Historic Preservation Office in 1974 to preserve the historical, archaeological, architectural, and cultural resources of New Hampshire
- Northern New England Passenger Rail Authority/*Downeaster*: Amtrak's rail service from Massachusetts to Maine
- Pan Am Railways (PAR): Operator of more than 2,000 route miles of railroad in the Northeast, including the track included in the Study corridor
- Public Service of New Hampshire (PSNH): New Hampshire's largest electric utility and owner/operator of the coal-fired Merrimack Station in Bow, New Hampshire
- Rivier University, Nashua, New Hampshire
- Rockingham Planning Commission: Planning commission serving the southernmost corridor communities
- Southern New Hampshire University, Manchester, New Hampshire
- Southern New Hampshire Planning Commission: Planning commission serving 13 communities in Southern New Hampshire, including the City of Manchester
- The Duprey Companies: Concord, New Hampshire Developer
- The Northern Middlesex Council of Governments: Regional planning agency serving nine communities in the Northeast region of Massachusetts
- Town of Bedford, New Hampshire
- Town of Bow, New Hampshire
- Town of Durham, New Hampshire
- Town of Exeter, New Hampshire
- Town of Hooksett, New Hampshire

- Town of Hudson, New Hampshire
- Town of Litchfield, New Hampshire
- Town of Merrimack, New Hampshire
- University of New Hampshire

Notes and details of stakeholder meetings can be found in Appendices 10a and 10b to the AA Final Report.

3.3 Public Involvement

The Study team held three public meetings at key Study milestones, one of which was a scoping meeting to satisfy FRA requirements:

- Study Initiation Public Meeting, Manchester, New Hampshire – June 5, 2013
- Public Scoping Meeting, Concord, New Hampshire – March 5, 2014
- Final Alternatives Meeting, Nashua, New Hampshire – November 20, 2014

Public meeting documentation can be found in Appendices 10a and 10b to the AA Final Report. Table 3.1 is a summary stakeholder outreach activities.

As a result of agency and stakeholder input, the following is a compilation of the most frequent comments and concerns:

- New Hampshire would benefit from a transportation system that provides multiple transit options, is less focused on single occupancy vehicles, and provides an increase in options that have the potential to ease traffic congestion and save commuting time.
- The Manchester-Boston Regional Airport is an important cog in the New Hampshire economy and a rail connection to the airport should be part of the Study.
- The state needs to work to attract and retain young professionals, who are now leaving New Hampshire at a faster rate than they are moving to the state.
- It is important to demonstrate the impacts and benefits of passenger rail to the state (economic, social, and environmental).

- The project needs to have a solid financial plan.
- State demographics are changing (the population is getting older), and the transportation system needs to address the needs of this changing demographic.
- The location of potential rail stations is important to many of the communities, and they would like to be part of the discussion in identifying appropriate locations.
- System safety needs to be analyzed.
- The fare structure for any system needs to be competitive with other forms of transportation.
- The frequency of operation needs to be competitive with other forms of transportation.
- The Study has many implications for development in New Hampshire, which needs to be quantified.
- Freight rail along the corridor is important, and the Study needs to examine the benefits to freight that could be realized by a passenger rail project.
- The project needs to quantify environmental impacts, including emissions, air quality, noise/vibration, etc.
- An increase in transit options has the potential to ease traffic congestion or slow the increase in traffic congestion in the state.
- Parking issues associated with potential rail stations is a concern in many communities.
- Any transportation study needs to include connections between rail/bus and other parts of the state, i.e., local transit systems.
- There is a concern among stakeholders that any proposed train service would negate the need for existing bus routes, which have been successful to date.
- A transparent process for the Study is important with a high-level of stakeholder and public engagement.
- Many stakeholders are interested in how passenger rail would impact the state's economy.

3.4 Website

A Study-specific website, http://www.nhcapitolcorridor.com, was developed to both disseminate and receive information about the Capitol Corridor AA Study.

3.5 Media Outreach

In cooperation with the NHDOT Public Information Office, notices of upcoming meetings were sent to the following local news media outlets:

- Print Media
  - Concord Monitor
  - Manchester Union Leader
  - Nashua Telegraph
  - Lawrence Eagle Tribune
- Broadcast Television
  - WBIN, Concord
  - WMUR, Manchester
  - TV 23, Manchester
  - TV 16, Nashua
- Radio
  - WEVO 89.1 FM, Concord
  - WGIR 610 AM, Manchester

3.6 Project Electronic Mailing List

A project electronic mailing list was developed with input from NHDOT, and maintained and used throughout the Study. Some individuals/organizations requested they be added to the list during public open houses, project briefings, or on the project website.

The mailing list is provided in Appendices 10a and 10b to the AA Final Report.

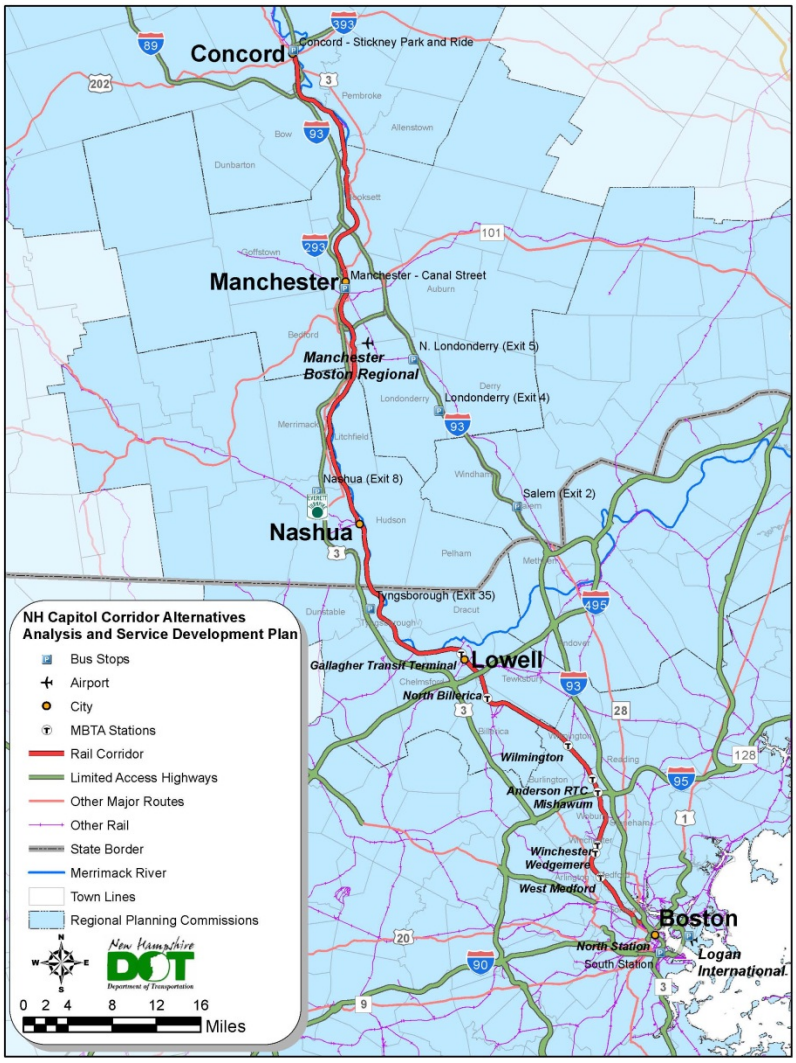
1 Introduction

1.1 Project Description

The Capitol Corridor Rail and Transit Alternatives Analysis (AA) is defining and evaluating opportunities to improve transit and/or intercity passenger rail service in the 73-mile corridor between Boston, Massachusetts and Concord, New Hampshire (Figure 1.1). While Massachusetts Bay Transportation Authority (MBTA) commuter rail service currently operates between Boston and Lowell, Massachusetts, commuter rail passenger service north of Lowell was discontinued in 1967. A public-private partnership, supported by the State of New Hampshire, operates roughly 50 daily bus round trips within the corridor between New Hampshire and Boston; this service typically carries 1,800 passengers per day.

Figure 1.1: New Hampshire Capitol Corridor Study Area



Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore options to improve transit service along the northern end of the Study corridor. Early in 2013, the New Hampshire Department of Transportation (NHDOT), working in concert with its counterparts in Massachusetts, started the Capitol Corridor AA, a 21-month project supported by both the Federal Railroad Administration (FRA) and Federal Transit Administration (FTA). The Study, which will be completed in late 2014, will evaluate a diverse set of rail and bus options for improving connectivity in the Study corridor by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93, and result in recommendation of a transit investment strategy that is responsive to local transportation needs and the region's economic, social, financial, and environmental context.

For purposes of the AA Study, the Capitol Corridor is defined as the area included in the Central New Hampshire Regional Planning Commission (CNHRPC), the Nashua Regional Planning Commission (NRPC), Rockingham Planning Commission (RPC), the Southern New Hampshire Planning Commission (SNHPC), the Merrimack Valley Planning Commission (MVPC), the Northern Middlesex Council of Governments (NMCOG), and the Boston Region Metropolitan Planning Organization (MPO) (Figure 1.1).

1.2 Study Corridor Dynamics

The Boston metropolitan area has expanded over the past several decades, first moving beyond Route 128/I-95, then I-495 in Massachusetts, and is now beginning to extend into southern New Hampshire. The Boston-based commuter-shed is now reaching beyond Nashua and Salem, and is continuing to move northward.

Expansion of the Boston metropolitan area and Boston-based commuter-shed has contributed to congestion in the Capitol Corridor, especially near Boston and particularly on I-93. This congestion results partly from the fact that Route 3 loses its freeway functionality south of Route 128/I-95, which negatively impacts traffic flow on the corridor's Lowell-Manchester side.

The congestion resulting from strong southbound commuting and non-work trip patterns is exacerbated by sprawl-type suburban residential development patterns throughout parts of southern New Hampshire, although there are some denser development patterns, particularly in Nashua and Manchester. Sprawl-type development contributes to increased vehicle miles travelled (VMT) throughout the corridor.

Business development and job creation in the corridor's northern half have not kept pace with residential growth, especially in high-technology sectors flourishing in the corridor's southern half; this residential/employment disconnect is exacerbating the transportation issues that are driving the Capitol Corridor Study.

Existing express bus commuter service is not attractive to a broad enough market and employs a park-and-ride strategy with a focus (mainly) on park-and-ride facilities located at or very near freeway interchanges. This strategy does not promote the dense, sustainable development that leads to reduced VMT.

1.3 Project History and Planning Context

As previously discussed, regular passenger rail service between Concord, New Hampshire and Boston, Massachusetts ended in 1967, with the exception of a brief restoration of service during a 1980-81 demonstration project. Since the 1980s, numerous studies and plans have supported the return of passenger rail service and expanded transit options in portions of this corridor. Following are a few examples of state-level recognition of the need for the Capitol Corridor AA Study:

- In 2003, the New Hampshire, Vermont, and Massachusetts DOTs commissioned a feasibility study for the Boston to Montreal rail corridor: *Boston to Montreal High-Speed Rail Planning and Feasibility Study Phase I: Final Report.* The study describes existing conditions, including those

from Boston, Massachusetts to Concord, New Hampshire, as well as a ridership analysis of corridor stations. The study found that "further study of associated operational, engineering, and cost/revenue factors is warranted," a recommendation that supports the AA Study.

- In 2004, NHDOT developed a draft Environmental Assessment, *Lowell, MA to Nashua, NH Commuter Rail Extension Project Environmental Assessment*, for the corridor segment from Lowell, Massachusetts to Nashua, New Hampshire in anticipation of extending MBTA commuter rail service to New Hampshire. Because the study focuses on a segment of the Capitol Corridor area, its environmental analysis can support the Capitol Corridor AA Study.
- In 2006, the Community Advisory Committee to the NHDOT Commissioner recommended expanded passenger rail as one of the five "initial action items" in its final report, a component of the state's long-range transportation plan.
- In 2007, the New Hampshire legislature created the New Hampshire Rail Transit Authority (NHRTA) to establish passenger rail service in New Hampshire.
- Beginning in 2007, New Hampshire invested $35 million in extensive new commuter bus services between greater Manchester, Nashua, and Boston. Service on I-93 was a commitment in the Environmental Impact Statement for improvements to the highway, and resulted from an extensive public scoping process that identified the need for expanded transit service. The project included the purchase of 16 coaches and construction of three bus terminals, two new park-and-ride lots, and coach service and storage facilities. The project also provided approximately $3.8 million for three years of operating support. NHDOT has also supported private bus service from Concord to Boston by purchasing buses and constructing a new bus terminal and park-and-ride lot in Concord. The state has determined that public investment in these transit improvements is needed to expand service and leverage the involvement of private bus companies, which could not undertake major commuter bus service expansion on their own. In spite of highway and transit improvements, the need for passenger rail service has grown due to increases in population and traffic in this corridor, as well as concerns about air quality, sprawl, and a reliance on single-occupant vehicles. The access of New Hampshire commuters, students, visitors, and other travelers to the Boston area is frequently disrupted by severe traffic congestion, weather incidents, and other factors that affect the highway system.
- In 2009, the *New Hampshire Climate Action Plan,* prepared by the New Hampshire Climate Change Policy Task Force, recommended expanded passenger service as part of a balanced transportation system.
- The 2010 *New Hampshire Capitol Corridor Project Overview Based on a White Paper Prepared for Amtrak* details this corridor's state-of-readiness to function as part of the federal High-Speed Intercity Passenger Rail (HSIPR) Program. Although the overview includes many elements of the Capitol Corridor Study, including proposed service, ridership forecast, capital costs, and economic impacts, the Study assumed Amtrak-operated service, so the completed work relates to only one potential alternative that will be studied through this project.
- Also in 2010, NHRTA commissioned the *Economic Impact of Passenger Rail Expansion along the New Hampshire Capitol Corridor.* The report assessed the economic impacts of restoring intercity passenger rail service between Boston, Massachusetts and Concord, New Hampshire.

The study supports the case that the implementation of passenger rail along this corridor is a net economic benefit for New Hampshire.

- In 2011, the University of New Hampshire Survey Center polled New Hampshire residents to assess attitudes about extending commuter rail service through the Capital Corridor. Findings of this *Granite State Poll for New Hampshire Rail Transit Authority* suggest a majority of residents strongly favor extending commuter service in New Hampshire, and a plurality of support using federal funding to study the issue.

1.3.1 Other Related Planning

A number of other relevant planning studies reference the Capitol Corridor, and are relevant to the current AA Study.

- The *Ten Year Transportation Improvement Plan* (2013-2022) includes a provision that requires legislative approval for capital and operating budgets associated with passenger rail service prior to expenditure.
- The *Massachusetts Department of Transportation Rail Plan* (2010) and the *New Hampshire State Rail Plan* (2012) identify the corridor as a potential for passenger service, and the New Hampshire plan recommendations include "implement recommendations of studies of the New Hampshire Capitol Corridor."
- The *I-93 Corridor Multi-Modal Transit Investment Study* (2009) does not focus on studying the New Hampshire Capitol Corridor, but recognizes it as a viable candidate for passenger rail service.

1.4 Project Purpose

The Capitol Corridor AA Study has the following purpose:

1. Identify and implement a transit and/or intercity passenger rail investment strategy that leverages the existing transportation infrastructure to improve connectivity to and from Boston, the region's largest economic hub
2. Diversify options and reduce single-mode reliance on roadways to move people and goods
3. Support mobility options that match emerging demographic trends and preferences in the corridor
4. Maintain the region's high quality-of-life through strategic infrastructure investments

1.5 Project Need

The Capitol Corridor dynamics described in Section 1.2 have contributed to the need for transit and/or intercity passenger rail investment within the Capitol Corridor, as described below.

Projected population growth will result in increased roadway congestion. As population density increases over the coming years, an increased number of multi-modal transportation options to Boston, the region's largest employment center, will be critical to mitigate corresponding increases in roadway congestion, particularly along I-93 and Route 3.

New Hampshire's existing transportation network does not effectively connect existing modes. Increased levels of corridor transit investment will improve local and regional mobility by linking travelers to the network of existing transportation modes: roadway, buses, commuter rail, heavy rail, light rail, bicycles, ferries, and airplanes. These increased linkages will improve ridership and usage across all modes, while promoting sustainable mobility.

The regional economy suffers from singular dependency on roads for movement of goods and passengers. Investing in transportation infrastructure that provides an alternative to roadway transport will link New Hampshire's businesses, industries, and residents to the national and New England transportation network.

Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents. A mismatch between locations of residence and employment forces many in New Hampshire to spend comparatively long periods of time commuting to work. Investing in more efficient transportation modes will not only improve connectivity between existing centers of residence and employment, but increased levels of multi-modal access may also catalyze additional business investment within New Hampshire.

New Hampshire is experiencing a young professional "brain drain." While the region's overall population is projected to grow in the coming decades, young professionals are choosing to leave southern New Hampshire to be closer to the employment and cultural and social opportunities associated with larger urban centers. Improved transit connectivity will support the attraction and retention of young professionals within the Capitol Corridor Study area.

New Hampshire is getting older. New Hampshire's senior population continues to grow. Additional shared transportation accommodations that support "car-light" mobility will be required to accommodate these emerging demographic and lifestyle trends, and will continue to make New Hampshire attractive to residents from childhood through retirement.

Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life. Population growth, if not guided through strategic infrastructure investments that promote efficiency, will result in uncoordinated development patterns and sprawl, diminishing the region's high quality-of-life and negatively impacting its unique character.

The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences. Expanding existing roadways and constructing new roadways will not be sufficient to sustainably accommodate the projected growth in travel demand, causing negative environmental consequences associated with an increased number of VMT and corresponding congestion.

2 Study Funding and Organization

The Study corridor's unique nature is reflected in its innovative combination of funding streams: the FTA and FRA are jointly funding this Study to ensure the broadest possible universe of alternatives is considered (both bus- or rail-based transit service and intercity passenger rail service) to meet the corridor's transportation needs. While these two funding streams are supporting one AA Study, each agency has designated use of their funds for specific tasks and geographies:

- **FTA** funding was limited to AA tasks related to transit service in the Concord-Boston corridor and included developing a range of alternatives for travel from Concord, Manchester, and Nashua to Boston; soliciting and evaluating public outreach and input on those alternatives; and developing recommended strategies along with an Environmental Assessment (EA) of those alternatives.
- To fully evaluate the intercity rail alternative, **FRA** funding was used to develop and screen alternatives, identify and analyze travel markets, and review existing services for the full 73-mile corridor. Tasks were limited to examining intercity rail alternatives in the corridor between Boston and Concord and included developing a Service Development Plan (SDP) and an EA.

This type of collaboration requires close coordination between a number of agencies beyond FTA, FRA, and NHDOT, including the NHRTA, Amtrak, PAR, Massachusetts Department of Transportation (MassDOT), corridor communities, and the Manchester-Boston Regional Airport (Manchester Airport).

3 Corridor Description

3.1 Population and Employment

Table 3.1 shows historical, existing, and projected population growth within the Study corridor. While the New Hampshire and Massachusetts corridor portions are projected to grow over the next two decades, the Massachusetts portion is projected to grow at a slightly faster pace. It can be anticipated that this population growth will increase demand on the transportation network, which may result in increased levels of congestion and travel times, particularly in the southern portion of the corridor which, as discussed in Section 3.4.1, already experiences intense levels of peak-hour highway congestion.

Table 3.1: Historical, Existing, and Forecast Population in the Capitol Corridor Study Area

Geography	1990	2000	2010	2020	2030	2035	Total Change 2010-2035	Percent Change 2010-2035
MA Study Area	3,474,873	3,666,175	3,782,361	3,942,000	4,093,000	4,182,000	399,639	10.6%

Source: Metropolitan Area Planning Council (MAPC), NMCOG, MVPC, NH Office of Energy and Planning (NH OEP)/CNRPC

As shown in Figure 3.1, the U.S.'s largest population group falls between ages 35 and 64. The percent of New Hampshire's total population that falls within that age group is higher than Massachusetts, New England, or the nation. As shown in Figure 3.2, the growth of New Hampshire's population over age 65 increased at a significantly faster rate between 2000 and 2011 than Massachusetts, New England, or the U.S.

As shown in Figure 3.3, the median age has increased within the Study corridor, New Hampshire, Massachusetts, New England, and the U.S. Increase in median age has been greatest within the Study corridor (four years), which is more than twice the nationwide increase in median age during the same time period (1.7 years) (Figure 3.4).

New Hampshire – and the Study corridor – are older and aging at a faster pace than the surrounding states and the nation. As New Hampshire's residents age, a robust multi-modal transportation that reduces reliance on single-car ownership will be necessary to support these residents' continued mobility and quality-of-life.

In addition to understanding existing and projected population growth, it is important to ensure that the specific needs of transit-dependent populations are considered when developing and evaluating transit investment strategies. These households rely on transit as a means to access employment, education, medical care, goods and services, and recreational opportunities; maximizing benefits to these populations while minimizing adverse impacts is important to transit investment success.

As shown in Table 3.2, 14 percent of households in the Massachusetts Study corridor do not have a car, compared to 4.4 percent of households in the New Hampshire portion. This difference likely reflects the fact that the Massachusetts portion has a significantly more dense and robust transit network (commuter rail, heavy rail, light rail, bus, express bus, and ferry) than the New Hampshire portion.

Table 3.2: Zero Car Households in the Study Corridor

Geography	Zero Car Households	Total Households	Percent of Households with Zero Cars

3.1.1 Employment

Massachusetts and New Hampshire forecast industry growth (by the North American Industry Classification System) out to 2020. Massachusetts organizes projections by Workforce Investment Areas (WIAs), while New Hampshire uses RPC jurisdictions. While the WIA boundaries do not exactly conform to the Capitol Corridor Study area, the four WIAs included in Table 3.3 below generally cover the Study area.

Table 3.3 reflects the projected three fastest-growing industries through 2020; the fastest-growing industry in each geography is in bold font.

The fastest growing industries in Massachusetts are – with the exception of construction – service-oriented industries: finance and insurance, professional, scientific and technical services, and other services. New Hampshire's fastest-growing industry – with the exception of professional, scientific, and technical services in Nashua RPC – is health care and social assistance, which does not even place in the top three in Massachusetts. This may reflect New Hampshire's comparatively high older population and the role of Boston as a regional finance, technology, and business service hub.

Table 3.3: Projected Changes in Industry Employment 2010-2020 (Five Highest Rates of Growth per Geography)

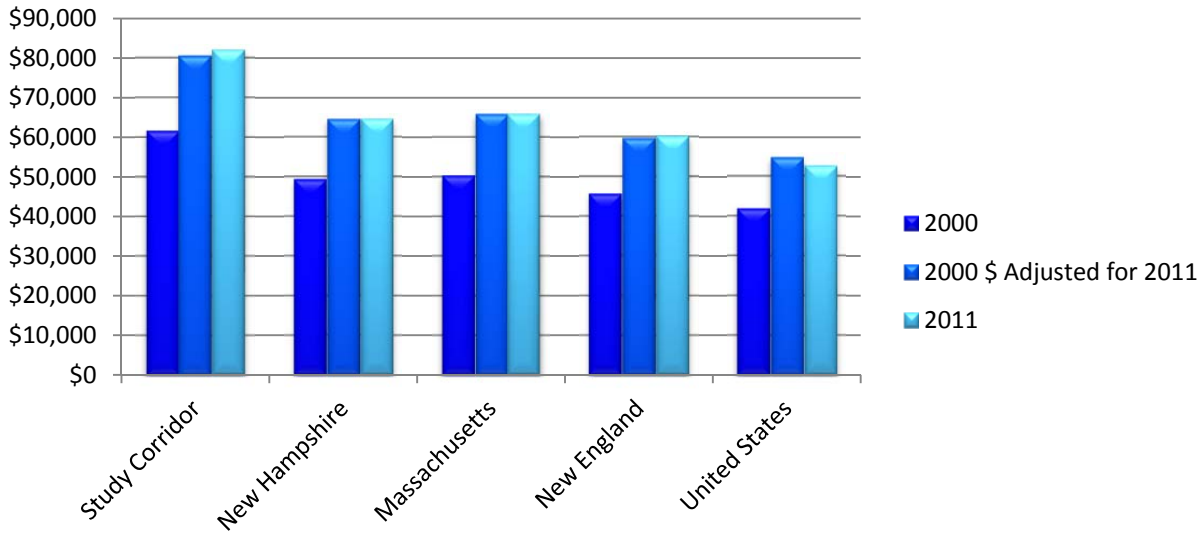
NAICS Industry	Massachusetts					New Hampshire			
	Boston WIA	Greater Lowell WIA	Lower Merrimack Valley WIA	Metro North WIA	North Shore WIA	Rockingham RPC	Central NH RPC	Southern NH RPC	Nashua RPC
Construction		**50.4%**			**41.2%**				
Wholesale Trade		49.3%			33.1%				
Retail Trade									
Transportation and Warehousing		33.7%							
Finance and Insurance				**59.5%**					19.7%
Professional, Scientific, and Technical Services	36.5%		**43.9%**	27.2%		22.4%	16.7%	22.9%	**25.5%**
Administrative/Support/Waste Mgmt./Remediation				24.2%	25.9%	18.6%	19.9%	18.9%	
Health Care and Social Assistance						**23.9%**	**25.4%**	**25.1%**	23.7%
Arts, Entertainment, and Recreation	32.9%		34.7%						
Other Services	42.8%		37.0%						

Source: Massachusetts Executive Office of Labor and Workforce Development, the Bureau of New Hampshire Employment Security

As shown in Figure 3.5, households within the Study corridor have a higher median income than New Hampshire, Massachusetts, New England, and the U.S.; this may reflect the fact that the Study corridor includes the largest cities in Massachusetts and New Hampshire (where residents tend to have higher incomes) and excludes the majority of the lower density, rural areas (where residents tend to have lower incomes).

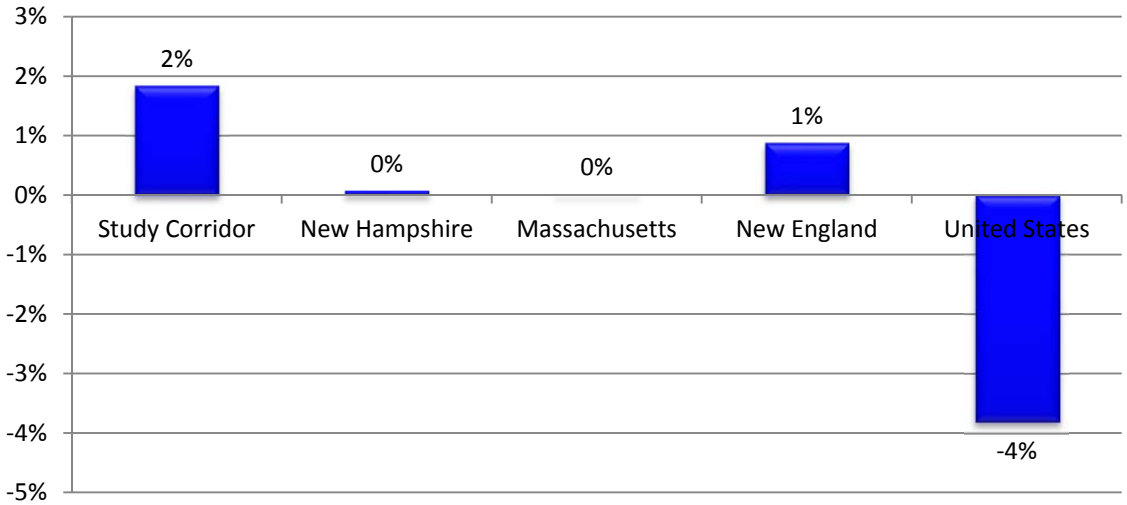
As shown in Figure 3.6, median household income within the Study corridor increased by two percent (in 2011 constant dollars) between 2000 and 2011, which outperforms New Hampshire, Massachusetts, New England, and the U.S.

Figure 3.5: Median Household Income, 2000 and 2011



Source: 2000 U.S. Census and 2011 Five-Year American Community Survey

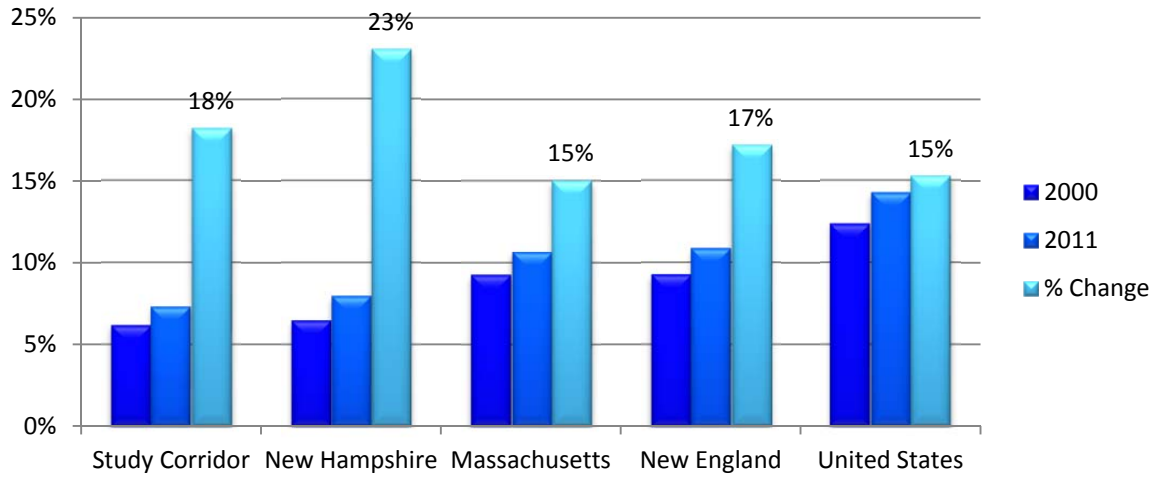
Figure 3.6: Percent Change in Median Income, 2000 to 2011 in 2011$



Source: 2000 U.S. Census and 2011 Five-Year American Community Survey

While the Study corridor has the lowest percentage of population living below the poverty line (Figure 3.7), that population increased 18 percent between 2000 and 2011. As the percentage of population living in poverty grows, providing these residents with lower-cost mobility options that reduce the need to own a car becomes increasingly important.

Figure 3.7: Percent of Population below the Poverty Line



Source: 2000 U.S. Census and 2011 Five-Year American Community Survey

3.2 Existing and Future Land Use

A legacy of New Hampshire's and Massachusetts' colonial past is prevalence of traditional town-center development, designed to support pedestrian, rather than vehicular traffic. This development style has a comparatively high-density mix of uses in the "downtown" that is easily accessed on foot from surrounding residential areas. While some infrastructure elements have been retrofitted to facilitate driving, the historic downtown development patterns of Boston, Lowell, Nashua, Manchester, and Concord (and other smaller towns within the Study corridor) elevate pedestrian and non-motorized transportation modes and reduce reliance on cars.

Another traditional land use pattern, particularly within the New Hampshire corridor, is rural farmland and open spaces. As discussed in Section 4.3.1, these land uses, and the environmental assets they preserve, are critical to New Hampshire's identity and a major factor in the continued high quality-of-life for New Hampshire residents.

As the population has grown over the decades and development has spread outside of traditional town centers and open spaces, auto-oriented, lower-density residential and commercial development patterns have emerged. These patterns, which can be found throughout the Study corridor, are typically dominated by land use segregation (as opposed to mixed use patterns found in town-centers).

Separated land uses are connected by comparatively few limited access roadways, which can result in increased levels of traffic congestion during peak travel times.

As discussed in Section 3.1, both Massachusetts' and New Hampshire's population is projected to grow over the next two decades; anecdotally, some of New Hampshire's growth can likely be attributed to the northward movement of Massachusetts residents. Regardless of the source, population growth will exert increased development pressure on New Hampshire's communities, which, in the absence of a strategic land use framework, could result in increased levels of congestion, encroachment into open spaces, and reduced quality-of-life.

Communities throughout New Hampshire and Massachusetts, including those within the Study corridor, have recognized potential costs associated with policy and regulatory inaction, and have undertaken numerous land use and development planning activities designed to encourage more sustainable land use patterns:

- **Granite State Future (ongoing).** This three-year collaborative strategic planning process among New Hampshire's nine RPCs (led by the Nashua RPC) will identify important local assets; incorporate shared values and opportunities into the planning process; plan for infrastructure investment; and conserve New Hampshire's natural, social, and financial resources while protecting its unique beauty and character.
- **New Hampshire Department of Environmental Service's *Innovative Land Use Planning Techniques* (2008).** This document highlights strategies and outlines model ordinances for towns and regions to use when developing community plans. These ordinances strive to preserve the rural character, enhance thriving downtowns, create or maintain a sustainable working landscape, and ensure that local businesses and development continue to thrive while minimizing negative impacts and costs. Some techniques described here include urban growth boundaries, infill development, and ways to implement Transit-Oriented Development (TOD).
    - The City of Nashua adopted a TOD district as part of its Land Use Code in January 2006. This district encourages mixed land uses within a half-mile radius of a potential commuter rail station area. The ordinance helps to support development that complements transit use while limiting conflicts between vehicles and pedestrians.
    - Another example is in the City of Concord, where in 1987 the city adopted a transit development goal as part of its long-term comprehensive plan.
- **City of Manchester, *Master Plan* (2009).** This plan promotes several goals focused on land use and transportation, including walkability, accomplished in part by having mixed land uses; alternative transportation options besides personal vehicles; sustainability, accomplished by mixed uses both within a neighborhood and within a building; a focus on the downtown, creating a transit center and updating the Central Business District zoning codes; and lastly, updating zoning codes to support mixed land uses – focusing on areas where higher residential density should occur and creating conservation zones to help maintain open spaces.

- **City of Manchester, *Toward a More Walkable and Livable Manchester* (2011).** This technical memorandum addresses the need to balance repairing old infrastructure and developing new infrastructure to support active living and encourage economic development, while maintaining a low tax base and affordability. Short-term and less expensive options are provided, as well as some higher cost options that capitalize on existing town assets. Specific recommendations include improvements to the Crystal Lake and West Granite neighborhoods.

  Crystal Lake:

  - Capitalize on the exiting utility corridor to create an eco-trail that connects the neighborhood to the lake, parks, schools, and other community assets
  - Modify Corning Road with narrower travel lanes, wider shoulders, better pedestrian crossings, and a mini-circle to support all users

  West Granite:

  - Improve the crossing at Main Street and Walker
  - Create an area master plan for the greater West Granite neighborhood
  - Create a vision plan for Main Street in the West Granite neighborhood

  The memo also provided two recommendations for the greater Manchester area:

  - Improve the trail that connects the west and east sides of central Manchester
  - Ensure sidewalks and pedestrian crossings exist on all streets where people should be expected and supported in walking and biking

- **City of Concord, *Master Plan 2030* (2008).** The City of Concord has a precedent of directing growth in a sustainable manner through the use of its Urban Growth Boundary, established in 1993. This plan also identifies the Opportunity Corridor – the city's highest priority for economic development, focusing on redevelopment and an intensive mix of land uses. The Opportunity Corridor runs north-south between the downtown and the Merrimack River and covers approximately 500 acres of land. The area was once home to industrial sites and manufacturing, but today those uses have been replaced by shopping malls, warehouses, and underutilized parcels well-positioned for redevelopment.
- **City of Nashua, *Guide to Transportation Planning* (2008).** This guide focuses on how to address the anticipated increase in demand that will be placed on transportation infrastructure. Some land use techniques suggested are consolidating development, encouraging mixed use, and limiting access to regional roadways – all of which can be accomplished by promoting nodal development patterns, following context sensitive solutions (CSS), and understanding bicyclists' and pedestrians' needs.
- **Southern New Hampshire Planning Commission, *New Hampshire Livable Walkable Communities Toolkit* (2012).** An update to a report completed in 2004, this report demonstrates a commitment to promoting physical activity for public health benefits throughout New

Hampshire and draws a connection between creating environmentally beneficial developments that increase walkability and enhance property values. The following are some techniques recommended to accomplish these goals:

- Mixed land uses, including urban agricultural uses
- Conserving and creating green space
- Access to transit for all incomes and stages of life
- Low-impact development
- Infill development incentives
- Flexible land use types
- Using vacant lots for recreational activities
- CSS

All of the above plans demonstrate local community commitment to regulate land uses to better serve residents' transportation needs. This type of guided development facilitates efficient growth while preserving the highly valued character and quality-of-life throughout the corridor.

3.3 Travel Patterns and Market Analysis

Market analysis provides a critical first step in estimating travel demand in the Study area via developing "big-picture" flows by quantifying the travel market's total size in the Capitol Corridor and key origin-destination travel patterns.

The Capitol Corridor's travel market geographic area is defined by the existing track alignment extending north from Lowell through proposed Nashua and Manchester stations, and ending in Concord. This corresponds roughly with the US Route 3 corridor in New Hampshire. The entire travel corridor varies by alternative, but, at maximum, stretches from the proposed Concord station in the north to MBTA's Boston North Station in the south. This section focuses on the New Hampshire market in the proposed extension area.[1]

The Capitol Corridor could be an extension of the MBTA commuter system. Work trips are the largest market of trips MBTA serves, representing approximately 87 percent of all MBTA commuter rail system trips.[2] This analysis focuses on the three main work-trip markets in the Capitol Corridor:

- New Hampshire to Massachusetts
- New Hampshire to New Hampshire

[1] The New Hampshire market is considered to be communities along the corridor and consists of Concord, Manchester, Nashua, Bow, Pembroke, Hooksett, Goffstown, Bedford, Londonderry, Merrimack, Litchfield, and Hudson

[2] MBTA ridership numbers are from the *MBTA System-wide Passenger Survey: Commuter Rail 2008-09 Report* published by the Central Transportation Planning staff in June 2010

- Massachusetts to New Hampshire

Mobility of individuals and their ability to reach places of employment, particularly to locations outside their areas of residence, is highly dependent on automobiles. Workers without an automobile, or access to one, are transit-dependent if they live beyond walking or biking distance of their jobs. The MBTA reports that only about 10 percent of all transit riders on its commuter rail system are transit dependent, so about 90 percent of riders are choice riders. Of these, nearly 81 percent cite the reason for riding is to avoid traffic.

Corridor population[3] within the proposed service catchment area is an important indicator of potential transportation infrastructure and service use. The corridor connects the three largest cities in New Hampshire: Concord, Manchester, and Nashua. These cities, as well as other communities in the corridor, represent nearly 39 percent of the population and just over 41 percent of employment in the entire State of New Hampshire. Concord, Manchester, and Nashua alone account for 24 percent of the population and just over 27 percent of employment in the state.

3.3.1 New Hampshire-to-Massachusetts Work-Trip Market

The New Hampshire communities within the corridor generate a total of approximately 200,000 work trips, of which over 28,000 (14 percent) are destined for locations in eastern Massachusetts. Of these 28,000 trips, approximately 10,000 (35 percent) are destined to locations along the existing Lowell Commuter rail line. These trips are the main component of the New Hampshire-to-Massachusetts work-trip market that would be served by the Capitol Corridor.

The main destinations of the New Hampshire work trips are Lowell and Boston/Cambridge. Lowell attracts just over 2,000 work trips from the corridor communities and Boston/Cambridge attracts just over 4,000. The Boston/Cambridge work trips face severe congestion during work commuting times and are considered a very strong market for Capitol Corridor service.

3.3.2 New Hampshire-to-New Hampshire Work-Trip Market

Of the approximately 200,000 work trips generated by New Hampshire corridor communities, just over 170,000 remain in New Hampshire and a large majority of these, nearly 148,000, stay within the corridor itself. Not all these trips are part of the market that the Capitol Corridor would serve due to project alignment, but they show the relatively large number of work trips within New Hampshire.

The intra-New Hampshire market consists primarily of work trips among Concord, Manchester, and Nashua. Excluding intracity trips, the work-trip market between these cities is over 9,000 trips.

[3] Population, employment, and commuting to work numbers are from the U.S. Census Bureau, 2006-2010 American Community Survey five-year estimates

3.3.3 Massachusetts-to-New Hampshire Work-Trip Market

This market is the smallest of the three major work-trip markets, with a total of 1,370 work trips from existing Lowell line communities to Concord, Manchester, or Nashua. The majority of these trips are from Lowell (773) and Boston (300). Similar to the trips to Boston, the trips from Boston face the severe commuting-period congestion.

3.3.4 Summary

- Work-trip markets are the major market to be served by the Capitol Corridor, and ridership on the MBTA system indicates the vast majority riders are choice riders who ride to avoid traffic
- The New Hampshire-to-Boston work-trip market is the largest and experiences the most congestion, making it a strong candidate to use Capitol Corridor service
- The intra-New Hampshire work-trip market is almost as large as the Boston market, but is not considered as strong as it does not face severe congestion of the Boston area; because these trips occur in the most traveled work corridor, they may be candidates for Capitol Corridor service
- The Massachusetts-to-New Hampshire work-trip market is the smallest, with more than half of the trips originating outside of Boston, making it the weakest of potential markets for Capitol Corridor service

3.4 Transportation Facilities and Services

The Capitol Corridor's robust transportation network includes roadways, highways, transit services, intercity passenger rail service, freight railroads, airport, and pedestrian and bicyclist facilities. Despite this network's dense, multi-modal nature, demand is exceeding capacity, particularly within the highway network (as described in Section 3.4.1), and opportunities exist to improve connectivity between the current modes.

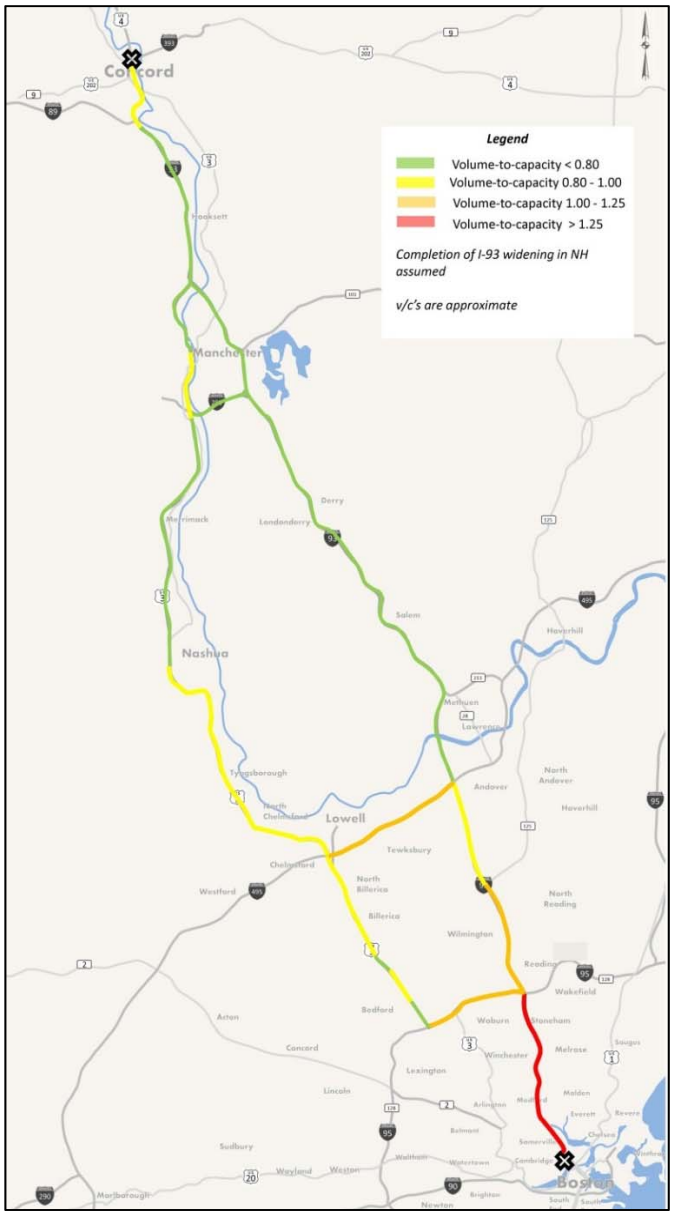
3.4.1 Highway Facilities

Limited access highways that connect New Hampshire's major population centers to metropolitan Boston are I-93, US Route 3/Everett Turnpike, Route 128/I-95, I-293, and I-495. These highways cover 134 miles of limited access freeway facilities and interchanges, shared between the States of New Hampshire and Massachusetts. The breakdown on the corridor mileage is as follows:

- I-93: 65 miles
- US Route 3: 49 miles
- Route 128/I-95: 11 miles
- I-495: 9 miles

The corridor has experienced rapid population growth, and many new residents commute to jobs in greater Boston. New Hampshire and Massachusetts have expanded the highway system to accommodate increasing traffic, and additional expansion is unlikely due to financial and environmental constraints. At a minimum, the advent of passenger rail service may delay the need for further highway widening. Traffic volume at the state line on the Everett Turnpike in Nashua grew by nearly 26 percent from 2002 to 2009 to 88,200 (average daily traffic), and continued traffic growth in the corridor in both states is projected. A recent review by the NRPC projects that average daily traffic on the Everett Turnpike will exceed capacity at several locations in 2020 (translating to a Level of Service D or below). This is consistent with earlier projections for the Massachusetts segment of the highway (US Route 3 in Massachusetts) that projected Level of Service F at peak hours by 2018, even with the additional lanes that have been constructed.

Figure 3.8: Existing Volume-to-Capacity Ratio during the Inbound Morning Peak



As shown in Figure 3.8, the highest levels of peak morning hour congestion are found closest to Boston. During peak hours, southbound travel speeds average less than 30 miles per hour (mph), traffic volumes exceed roadway capacity by more than 25 percent, and average speeds within eight miles of Boston dip to as low as 12 mph.

Contributing factors to the severe traffic congestion experienced entering and departing Boston are the current freeway infrastructure, limited managed freeway lanes, and insufficient commuter transit options.

On the infrastructure side, south of Exit 28 in Somerville, Massachusetts, the three general purpose (GP) lanes on I-93 southbound drop to two for more than 1,000 feet before picking back up the third lane at Exit 29. This lane drop, less than four miles from Boston, is currently a choke point causing severe congestion on I-93 on typical weekday morning conditions.

Outside of Boston and Massachusetts, I-93 North is currently being widened to four GP travel lanes in each direction in New Hampshire between Exits 1 and 5 from the Massachusetts state line (Salem, New Hampshire) to Manchester, approximately

19.8 miles. This widening will add peak-hour vehicular capacity and facilitate more efficient traffic operations in New Hampshire. However, the future lane imbalance with the I-93 southbound lane drop from four lanes to three lanes between the New Hampshire state line and Exit 41 in Wilmington, Massachusetts for approximately 11.5 miles is expected to be a key choke point and source of congestion in the future morning peak period.

In the northbound direction during the afternoon peak period, after Exit 41 and the Route 125 interchange, I-93 northbound has a lane drop and three GP lanes are carried up to the New Hampshire state line. In the future, this lane drop from four to three lanes at Exit 41, and back to four lanes in New Hampshire, is expected to be a choke point and source of peak-hour congestion in weekday afternoons.

The peak period breakdown travel lanes on I-93 northbound and southbound between Exits 45 and 47 will be removed as part of the Methuen interchange reconstruction at Route 110/113 and I-93.

3.4.2 Transit and Intercity Passenger Rail Service and Facilities

The Capitol Corridor has a variety of commuter and local bus operators, as well as MBTA commuter rail service and Amtrak intercity passenger rail service on the *Downeaster* line.

Regional and Local Bus Service

Seven regional and four local bus operators provide service within New Hampshire and intercity service to Boston and beyond. Boston Express (BX) provides the primary commuter service within the Study area along the heavily congested Massachusetts segments of I-93. The service was initially introduced by NHDOT as a mitigation measure during highway construction along I-93. Concord Coach also provides intercity service to Boston along the central spine of New Hampshire as far north as Berlin. In Massachusetts, MBTA and the Merrimack Valley Regional Transit Authority (MVRTA) also provide commuter service to Boston along I-93 from communities to the north. Each of these services has access to the High Occupancy Vehicle (HOV) lane on I-93 that stretches 2.5 miles between the Shore Drive overpass in Somerville and the Zakim-Bunker Hill Bridge.

Additional New Hampshire regional bus service between communities outside the Study area and to Boston operates through the Study area or along segments of the corridor, as follows:

- Dartmouth Coach provides service from Dartmouth University in Hanover, New Hampshire and White River Junction, Vermont to Boston and travels non-stop through the Study area along I-89 and I-93
- Service to and from the New Hampshire Seacoast is operated by C&J from Dover, Durham, and Portsmouth, New Hampshire and Newburyport, Massachusetts to Boston and New York City
- Greyhound provides intercity service from Boston to Manchester, Concord, and points north and west; Greyhound also provides service from Boston to Nashua via Worcester and Leominster, Massachusetts

Local bus service within the New Hampshire Study area is provided by Concord Area Transit, Manchester Transit Authority, and Nashua Transit Service. Local bus service in Massachusetts is provided within the

Study area by the Lowell Regional Transit Authority. Interconnections between these local providers are limited.

Existing traffic congestion along I-93 and Route 3 significantly impact commuter bus scheduled travel times. For instance, BX's 6:30am southbound departure from Londonderry (Exit 4) on the I-93 service is scheduled for a one-hour trip to Boston's South Station. Meanwhile, the 9:50am southbound departure is scheduled for a two-hour 20-minute trip, which is a built-in or induced delay of one hour and 20 minutes.

MBTA Commuter Rail Service and Amtrak *Downeaster* Service

On a typical weekday in 2013, Lowell was served by 44 MBTA revenue trains to and from Boston's North Station (Table 3.4). The 25-mile trip serving up to seven intermediate station stops takes 44 to 49 minutes. Six weekday non-revenue "deadhead" trains run between Lowell and Boston to stage the service because there is no facility for train overnight storage or maintenance in Lowell.

Typical weekday MBTA ridership on the entire line is 17,500 passenger trips, including both northbound and southbound travel. Lowell is the busiest station on the line with 4,280 weekday boardings and alightings. Running time between Lowell and Boston ranges between 45 and 49 minutes with a maximum allowable speed of 70 mph. The daily schedule includes approximately 150 daily deadhead train miles.

Table 3.4: MBTA Service, Ridership, and Revenue Statistics

Station	Mile Post	Weekday Revenue Trains		Typical Weekday Southbound Boardings (MBTA Only)	MBTA Cash Fare	Average Revenue per Passenger Boarding (MBTA)	Typical Total Weekday Passenger Revenue (MBTA)
		MBTA	Amtrak				
Lowell	25.5	44		2,141	$6.75	$6.67	$28,566
North Billerica	21.8	44		1,427	$6.25	$6.38	$18,195
Wilmington	15.2	47		758	$5.25	$5.09	$7,711
Woburn	12.6	57	10	1,743	$4.75	$4.77	$16,640
Mishawum	11.9	6		50	$4.75	$4.95	$495
Winchester	7.8	49		1,002	$4.25	$4.34	$8,701
Wedgemere	7.3	48		740	$4.25	$4.36	$6,459
West Medford	5.5	49		884	$1.70	$1.83	$3,244
North Station	0	58	10	n/a	n/a	n/a	n/a
Totals		**58**	**10**	**8,745**		**$5.15**	**$90,011**

Source: MBTA Conductor's Audit Reports Thursday – February 9, 2012 and Jacobs Analysis

In addition to the Lowell service, MBTA runs a limited number of trains to and from Haverhill via Woburn and Wilmington to avoid conflicts on the Haverhill line south of Lawrence. Most of these trains serve passengers at the Anderson Regional Transportation Center (Woburn) and Wilmington. Six southbound and one northbound train operate along this so-called "Wildcat Route."

Amtrak passenger train service between Boston and Portland was restored in 2001 after an absence of more than 35 years. On November 1, 2012, service was extended to Freeport and Brunswick, Maine. The *Downeaster* service (Figure 3.9) features five daily round trips between Portland and Boston's North Station, with eight intermediate stops – Woburn, Haverhill, Exeter, Durham-University of New Hampshire (UNH), Dover, Wells, Saco, and in season, Old Orchard Beach. Two of those five daily round trips extend north of Portland to serve the Freeport and Brunswick stations. Ridership on the *Downeaster* service in Fiscal 2013 was nearly 560,000 passengers, up 3.4 percent from the year before. Most trains make the Boston-Portland trip in two hours, 30 minutes. Track work and speed increases in 2004 and 2007 have allowed a 15- to 20-minute schedule reduction in recent years.[4]

Figure 3.9: Amtrak *Downeaster* Service

3.4.3 Freight Railroad Facilities

The New Hampshire Main Line (NHML) was, and remains, a principal artery of the Boston and Maine Railroad's (B&M's) network and a key economic link between the Granite State and the national economy. Since the 1980s the B&M has belonged to a regional amalgam of railroads initially called the Guilford Rail System, later changing its name to PAR. Today PAR, headquartered in Billerica,

[4] Amtrak Fact Sheet, Fiscal Year 2013, State of New Hampshire

Massachusetts, owns and operates the former B&M and Maine Central Railroads as an integrated system, roughly running from Bangor to Albany with numerous branches in New Hampshire and other New England states. North of Chelmsford, PAR refers to the route as its "Northern Branch."

Once a busy mainline railway, the NHML was double tracked to Concord and beyond, but today the railway is largely a single track north of Lowell with some passing sidings, a yard in Nashua, and numerous turnouts to customer sidings.

In New Hampshire, the NHML is property of PAR. In Massachusetts, the southernmost 34.5 miles of the line was acquired by the MBTA in the 1960s. The MBTA acquired most mainline assets of the B&M and New Haven Railroad in eastern Massachusetts at that time. Today the southernmost 25.4 miles of the route between Boston and Lowell are busy with passenger traffic operated by the MBTA and Amtrak with some local freight services operated by PAR.

In 2011, PAR conveyed trackage rights for the operation of passenger trains on the NHML northward into New Hampshire between the state line and Concord.

New Hampshire and the rest of New England are often referred to as a "cul-de-sac" in the national rail network, since the area is primarily a freight destination, and no major rail routes traverse the region. Due to the Class I network geography, rail volumes in New Hampshire and New England tend to be considerably lower than most other states.

Approximately 85 percent of national rail freight tonnage is bulk commodities, those most commonly shipped to New Hampshire being coal and petroleum products bound for local consumption. The commodity most commonly shipped from New Hampshire is sand and gravel, bound for cement and asphalt plants in Massachusetts. Almost 80 percent of the rail cars moving through the state are through movements between Maine, Eastern Canada, and the balance of the U.S.

The NHML's only connection to the national freight network is at Lowell, Massachusetts. This corridor currently receives 75 percent of all rail freight tonnage shipped into New Hampshire. While the freight received is quite diverse, traffic flow is dominated by coal for electric generation shipped at Bow.

Unless there is a major shift New Hampshire's economy to produce, process, or consume large volumes of bulk commodities such as paper, chemicals, or energy, it is unlikely that the total volume of rail traffic to or from the Granite State on the NHML (or any other line) will grow at a rate that varies significantly from expected population growth as now most rail traffic shipped to New Hampshire is for local consumption and the volume of outbound rail traffic other than building materials is quite minor. However, rail freight in New Hampshire could benefit from improvements in the condition of a key rail line serving major population centers, but the magnitude of that overall benefit for long journeys on the national network will likely be relatively small.

3.4.4 Bicycle and Pedestrian Facilities

The State of New Hampshire, its regional planning commissions, and communities within the Capitol Corridor have underscored the importance of bicyclists and pedestrians to the transportation network by creating bicycle- and pedestrian-friendly plans:

- Regional Trails Coordinating Council, CNRPC, SNHPC, *Regional Trails Plan, Salem-Manchester-Concord* (2012)
- SNHPC, *New Hampshire Livable Walkable Communities Toolkit* (2012)
- City of Concord *Bicycle Master Plan* (2010)
- NHDOT, *New Hampshire State Trails Plan* (2005)
- Rizzo Associates and Alta Planning and Design, *Salem to Concord Bikeway Feasibility Study* (2003)
- NHDOT, *New Hampshire Statewide Bicycle and Pedestrian Plan* (2000)

The City of Boston's Hubway bike sharing program, opened in 2011, has more than 1,000 bikes stationed at 104 docks throughout Boston and Cambridge. A bike station serves every line of the T, commuter rail, and ferry, as well as 64 bus routes. The five most-used bike docks are located at either T or commuter rail stations; more than 600,000 Hubway rides have been taken.

This awareness and subsequent infrastructure investments in improved bike-pedestrian mobility will support Capitol Corridor transit investment by expanding low-cost, environmentally-friendly, and health-conscious access options to transit stations and final destinations within the corridor.

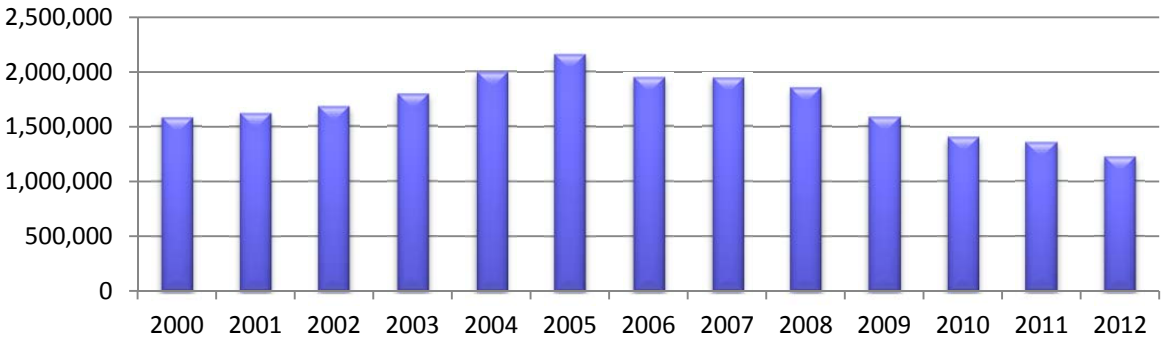
3.4.5 Airports

The corridor will provide an additional transit connection between the Manchester Airport and Boston, creating a system in which the three principal Boston-area airports are connected (with rail connection to Providence). Manchester Airport is an important economic engine for New Hampshire and the region – creating jobs, facilitating commerce, and providing access to the global marketplace. Manchester Airport contributes more than $1 billion annually to the region's economy and accounts for more than 3,500 jobs in the three-county region contiguous to the airport. The airport connection, through an intermodal station adjacent to a new airport access highway, will create new rail-air connectivity.

Manchester Airport strongly supports development of passenger rail service in New Hampshire as part of a multi-modal solution to meet the region's growing and changing transportation needs. The airport incorporated a review of passenger rail service (and an anticipated airport rail station) as a focus of its 2011 *Master Plan Update* and identified important synergies between passenger rail and air passenger transportation systems. Manchester Airport will benefit from both enplaning passenger (air travelers originating from the area and using passenger rail service to travel to the airport from their home or business) and deplaning passenger (air travelers accessing New England through Manchester Airport and using passenger rail service to travel from the airport to their final destination) rail ridership. Visitors using Manchester Airport to access the region for business and leisure spent $752.8 million in 2008, and a rail connection is considered critical to attract additional visitors, especially on international flights.

The airport's annual enplanement statistics are shown in Figure 3.10. The 2011 *Manchester-Boston Regional Airport Master Plan Update* projects 1.9 to 2.3 million enplanements in 2020 and 2.3 million to 2.8 million enplanements in 2030.

Figure 3.10: Manchester Airport Enplanements, 2000 to 2012



Source: Manchester Airport Master Plan

Boston's Logan International Airport is currently New England's largest transportation center and ranks 20th in the nation in passenger volume, employs approximately 12,000 workers, and stimulates the New England regional economy by approximately $7 billion per year.[5] Increased multi-modal connectivity to this airport will provide Study corridor residents and visitors with expanded aviation access to their destinations while also supporting economic development activity.

4 Travel Demand and Sustainability

4.1 Increasing Travel Demand

Travel from New Hampshire to Boston is predominately made by auto trips in one of two main corridors: either I-93 or a combination of US Route 3, Route 128/I-95, and other routes.

Within Massachusetts, the Boston MPO predicts that average daily highway trips into Boston from the north and northwest corridors, which include the Massachusetts Study corridor, will increase from 176,100 to 186,500 between 2008 and 2030, approximately six percent. This growth may be somewhat

[5] http://www.massport.com/logan-airport

restricted by existing corridor capacity constraints, as I-93 and the junction of Route 3 and Route 128/I-95 are considered to be one of the worst bottlenecks in the north corridor.[6]

In terms of traffic volumes on Route 3 and I-93, the Boston MPO's travel demand model forecasts large traffic volume increases just north of Route 128 by 2030. Route 3 is predicted to carry 120,400 vehicles per day by 2030, a 37 percent increase over current volumes. I-93 traffic volumes are forecasted to increase to 187,100 by 2030, an increase of 19 percent.

The Nashua MPO predicts that by 2035 the entire Route 3 corridor from Bedford to Massachusetts will experience a volume of greater than 60,000 vehicles per day. Currently the volume ranges from 53,300 at the Bedford tolls to 124,300 at Exit 5.[7]

The Manchester MPO forecasts volumes on I-93 to increase by about 15 percent between 2012 and 2040, peaking at 76,500. South of Manchester both Route 3 and I-93 are anticipated to experience major growth in volume, with I-93 having the greater increase. Volume on I-93 in Derry is currently 69,000 and is forecasted to be 121,400 by 2040, a 76 percent increase. The volume on Route 3 in Bedford is currently 42,600 and forecasted to be 66,000 in 2040, a 55 percent increase.[8]

Overall, within the corridor, traffic volumes are estimated to increase in the future. Data indicates that the most severely congested areas will grow the least in terms of volume due to current capacity constraints. Areas in the corridor with less congestion today are expected to have the greatest increase in future traffic volumes as excess capacity is utilized.

4.2 Economic Development and Land Use

4.2.1 Access to Boston-based Employment

Transit investment within the Capitol Corridor will improve multi-modal connectivity between New Hampshire's residents and Boston, the region's major employment center. As shown in Section 3.1, the New Hampshire and Massachusetts corridor portions are projected to experience population growth in the same industries. The Massachusetts portion is also projected to experience growth in a few industry segments less common in New Hampshire. Expanded access to this diversified employment base will benefit existing New Hampshire residents, and may encourage them to stay in their current communities rather than move closer to Boston.

[6] *Paths to a Sustainable Region*, the current Long Range Transportation Plan for the Boston metropolitan region, adopted by the MPO on September 22, 2011
[7] *Nashua Metropolitan Area Long Range Transportation Plan 2011-2035*; adopted October 20, 2010
[8] *FY 2013-FY 2040 Regional Transportation Plan, Southern New Hampshire Planning Commission*, October 23, 2012

4.2.2 Business Attraction in New Hampshire

In addition to improved access to Boston's employment market, transit investment in the corridor may be leveraged to lure businesses into New Hampshire. As discussed in Section 4.3.1, Millennials – the 18- to 34-year olds that will rival the Baby Boomers in size and cultural influence – have repeatedly stated a preference for built environments that support a car-light or car-free urban-style existence. These Millennials are the rising "creative class" – those workers whose career orientation is towards ideas and innovation rather than heavy manufacturing and assembly lines. As businesses, particularly technology-oriented businesses, look for lower-cost alternatives to downtown Boston and more Millennial-friendly environments than in the Route 128 corridor, Capitol Corridor communities can increase their attractiveness through transit investment. Improved connectivity will not only improve access to Boston-based employment, but can draw these "creative class" workers (and the companies that want to hire them) into the New Hampshire corridor.

4.2.3 More Strategic and Efficient Land Use Patterns

Access to the Boston-based employment market and the attraction of businesses into New Hampshire rely on the efficient flow of people between their homes and places of employment. As discussed in Section 4.1, travel demand within the Study corridor is anticipated to increase, which, in the absence of transportation network investment, could lead to increased levels of congestion and decreased levels of mobility. Simply expanding the roadway network is not a solution to this problem – it would likely induce additional demand, which would exacerbate congestion.

While mobility problems are most directly solved by transportation investment, land use plays a critical role in supporting the efficient movement of people and goods. In addition to using transit system investment to expand transportation network capacity, strategic land use planning that focuses higher-density, mixed use development near transit stations can reduce demand on the transportation network by supporting trip efficiencies. This land use pattern is a return to the traditional New England "town-center" style of development.

More efficient land use patterns can also result in employment opportunity expansion closer to home, which could reduce overall demand on the transportation network (because of shorter travel distances) and reduce overall travel times (shorter distances and reduced congestion).

4.3 Sustainability and Quality-of-Life

4.3.1 Sustainability

A sustainable transportation system is one that meets and balances a community's existing environmental, social, and economic needs without compromising resources for future generations. The following discussion is an overview of the current state of these factors in New Hampshire, and how alternatives developed as part of this Study will address transportation system sustainability.

Environmental

Part of the New Hampshire character is rooted in the state's natural beauty, including its mountain ranges, chains of lakes, sea coast, and protected forest land. Increased levels of development and corresponding growth in transportation network demand may negatively impact these environmental assets unless proactive investments in sustainable infrastructure are pursued.

New Hampshire's Energy, Environmental, and Economic Development Benchmark Report, released by the New Hampshire Energy and Climate Collaborative in 2012, reports on the state's environmental factors. According to the latest report, transportation accounts for 35 percent of the energy use and 46 percent of the Greenhouse Gas (GHG) emissions. Total transportation-related energy consumed and GHG emission rates have remained flat in recent years, even though VMT and per capita VMT have decreased approximately five percent between the peak in 2006 and the most recent data in 2009. At the same time, public transit ridership increased 25 percent between 2000 and 2010.

Because the New Hampshire Capitol Corridor is home to the three largest cities in the state (Concord, Manchester, and Nashua) as well as two major north-south arteries (Route 3 and I-93), transportation network investments that support mode shift from cars to transit are likely to support a decrease in per capita VMT and may support reductions in GHG emissions.

Economic

The New Hampshire Center for Public Policy Studies' *From Tailwind to Headwind: New Hampshire's Shifting Economic Trends*, published in 2012, found that demographic trends in the state are related to economic trends. The report found that the state's economic advantage has traditionally been rooted in three areas: consistent population growth, increased productivity, and a more resilient economy than its competitors. However, data shows that population growth is slowing, labor force participation is declining (due to an aging population), and the rate of growth in educational attainment is slowing.

Like the Baby Boomer generation before them, the sheer size of the Millennial generation, those born between approximately 1982 and 2003, means their preferences will shape every aspect of the country's economy and culture in the coming decades. Communities investing in infrastructure and making policy decisions that are attractive to this generation will be successful in creating an economic framework for sustainable growth. This is particularly important for New Hampshire, which is aging at a higher-than-average rate. A 2013 report by U.S. Public Interest Research Group, *A New Direction: Our Changing Relationship with Driving and the Implications for America's Future*, concluded the following:

- Young people aged 16 to 34 drove 23 percent fewer miles on average in 2009 than they did in 2001– a greater decline in driving than any other age group; the severe economic recession was likely responsible for some of the decline, but not all
- Millennials are more likely to want to live in urban and walkable neighborhoods and are more open to non-driving forms of transportation than older Americans

- If the Millennial-led decline in per capita driving continues for another dozen years, even at half the annual rate of the 2001-2009 period, total vehicle travel in the U.S. could remain well below its 2007 peak through at least 2040 – despite a 21 percent increase in population

The Capitol Corridor is home to one of the largest private employers (BAE Systems) and the largest pool of labor resources. Transit investment within this corridor will provide a lower-cost commuting alternative that links New Hampshire residents with employment opportunities in Boston while increasing New Hampshire's attractiveness as a place to do business.

Social

In his 2012 report *New Hampshire Demographic Trends in the Twenty-First Century*, Kenneth Johnson of the Carsey Institute at the UNH documents four main trends that can be extracted from the most recent census data: New Hampshire's population increase is slowing, New Hampshire's population is aging, the pace of demographic change is uneven in the state, and the state is becoming more diverse. Young adults are migrating to metropolitan cores, family age residents are migrating to suburbs, major metropolitan cores are losing older residents, and rural counties are losing young adults. Many towns in the Capitol Corridor, including Manchester and Nashua, have the largest percentage of population under the age of 18 in the state.

4.3.2 Quality-of-Life

Granite State Future, a statewide project coordinating development of regional plans in each RPC jurisdiction, recognizes the interconnection between development patterns, availability of housing choices, and diversity of transportation choices as a means to preserve natural resources and community vitality and promote energy efficiency. Transit investment within the Capitol Corridor will be a powerful investment that can be leveraged to implement this regional, multi-discipline vision to maintain New Hampshire's high quality-of-life.

5 Goals and Objectives

To determine how well transit and/or intercity passenger rail investment within the Capitol Corridor will address regional and corridor needs, a set of goals, objectives, and evaluation measures have been developed. Goals and objectives, outlined in Table 5.1, build on the work that has been completed or is ongoing within the corridor and region, as described in Sections 1.3 and 3.2. Each goal reflects an understanding of the role that integrated transportation and land use planning can play in supporting an economically, environmentally, and socially sustainable community. Transit investment will be a major step in implementing an integrated planning approach within the Capitol Corridor.

Table 5.1: Capitol Corridor AA Study Goals and Objectives

Goals	Objectives
Transportation and Mobility Leverage the existing transportation network to improve access and mobility within the corridor and throughout the region	▪ Provide alternatives to address congestion within the Study corridor ▪ Expand transit network capacity ▪ Increase transit ridership/mode-share by expanding existing rider base and attracting new riders ▪ Provide travel time savings ▪ Improve transit service efficiency, convenience, and reliability
System Integration Invest in transportation improvements that complement the existing multi-modal transportation network	▪ Increase corridor modal connectivity ▪ Provide connections to other corridors within the region ▪ Increase access to the Manchester Airport through additional transit service ▪ Balance system capacity (MBTA, BX, Concord Coach) ▪ Ensure operating efficiency
Economic Development and Land Use Support the vision for growth laid out in local/regional development plans	▪ Improve access to higher-paying jobs in greater Boston ▪ Support development patterns/lifestyle choices that attract younger, highly educated professionals to New Hampshire ▪ Leverage younger, highly educated employee base to attract new businesses/grow existing ones ▪ Promote TOD to mitigate sprawl development patterns ▪ Improve the potential for additional freight rail business through infrastructure upgrades
Sustainability Support transportation investments that contribute to an environmentally, economically, and socially sustainable community	▪ Leverage existing transportation infrastructure to qualify for federal transportation investment dollars ▪ Mitigate potential adverse environmental impacts resulting from anticipated development ▪ Support growth patterns that attract and retain residents from childhood through retirement ▪ Improve access to other tourism, recreation, and cultural attractions in greater Boston and New Hampshire

5.1 Evaluation Criteria

As the project progresses, a series of evaluation criteria, based on project goals and objectives, will be developed to help determine the degree to which transit investment within the Capitol Corridor would address the project Purpose and Need. This iterative evaluation process will include two progressively more detailed levels of evaluation that use quantitative measures and qualitative assessments, and will likely include the following criteria:

- Conceptual alternatives
    - Capital and operating costs
    - Ridership
    - Land use and economic development
    - Environmental fatal flaws
- Detailed alternatives
    - Capital costs
    - Operations and maintenance (O&M) costs
    - Ridership
    - Transit-supportive land use and economic development
    - Cost effectiveness (using FTA calculations)
    - Benefit cost (using FRA calculations)
    - Environmental impacts
    - Environmental justice

5.2 FTA New/Small Starts Criteria

The project may be seeking discretionary FTA funding through either the New Starts or Small Starts funding programs. Both are highly competitive discretionary programs that require project sponsors to demonstrate, among other project components, a realistic, defensible financial plan to fund the project's capital and O&M costs.

To be eligible for a New Starts grant, total project capital costs must exceed $250 million and project sponsors must pursue more than $75 million in federal capital funding assistance. The Small Starts program has been designed to allow comparatively less capital-intensive transit investment projects to participate in a streamlined federal funding review and approval process. Projects with estimated total capital costs of less than $250 million that are seeking up to $75 million in federal funding are eligible for review under the streamlined Small Starts project development process.

In accordance with the current federal surface transportation law, called Moving Ahead for Progress in the 21st Century (MAP-21), FTA developed and uses a series of criteria to decide whether applicant projects may advance into project development, and to evaluate and rate projects in support of funding

recommendations. FTA criteria for both the New Starts and Small Starts programs are shown in Figure 5.1 and Figure 5.2.

Figure 5.1: Project Justification (50% of Overall Rating)

Figure 5.2: Local Financing Commitment (50% of Overall Rating)

5.3 FRA Criteria

To advance the Capitol Corridor initiative into the FRA's "pipeline of future projects," NHDOT will lead three work activities:

1. Develop a detailed SDP supported by the many stakeholders necessary to develop the service
2. Prepare the environmental analyses and documentation necessary to satisfy National Environmental Policy Act (NEPA) requirements
3. Complete preliminary engineering for all track and signal improvements needed to implement the planned service

The completed SDP will address the following topics:

- **Program Rationale:** A description of the corridor's transportation challenges and opportunities based on current and forecasted travel demand and capacity conditions. The purpose of an SDP is to show FRA how the proposed service can cost-effectively address transportation and other needs considering system alternatives (bus, highway, etc.). Qualitative and quantitative assessments of each alternative's costs, benefits, impacts, and risks will provide decision-makers with sufficient information. The SDP might also explore synergies between the intercity passenger rail proposal and large-scale goals and development plans within its service region and communities.
- **Operations:** The operating strategy will be based on a comprehensive and coordinated review of service development options reflecting stakeholder input and perspectives for project success. Without a viable operating strategy no other project element can be successful. Up to three alternative strategies will be developed and reviewed to build the recommended approach. Alternatives will reflect a range of collaboratively developed investments in infrastructure and service that satisfy stakeholder requirements and aspirations.
- **Capital Needs:** A description of the rail equipment and infrastructure improvements for each discrete phase of service implementation, including estimated capital costs, assumptions, and methods; estimated capital expenditures necessary to bring the service to its full operating capability; accommodation of future traffic growth; and ongoing expenditures system component replacement.
- **Operating and Financial Results:** Operating and financial projections for each phase of the planned intercity passenger rail service.
- **Public Benefits:** A description of user and non-user benefits and, to the extent readily quantifiable, the estimated economic value of those benefits.
- **Program Implementation:** An implementation plan that establishes the framework of understandings and agreements and defines the road map to lead the recommended transit strategy from conceptual plan to operating reality.

Appendix 3

TECHNICAL REPORT
Task 3: Financial Plan

October 2014

Alternative	Daily Rail/Bus Service	Capital Cost (millions)	Annual O& (millions)
Concord Regional	8 trains (4 round trips) to Concord and Manchester 30 trains to Nashua	$205 - $245	$7 - $10
Concord Commuter	18 trains to Concord 22 trains to Manchester 26 trains to Nashua	$185 - $225	$11 – 15
Manchester Regional	16 trains to Manchester 34 trains to Nashua	$145 - $185	$8 - $12
Manchester Commuter	20 trains to Manchester 30 trains to Nashua	$145 - $185	$8 - $12
Nashua Commuter	34 trains to Nashua only	$105 - $145	$5 - $9
Nashua Minimum	16 trains to Nashua only	$105 - $145	$5 - $7

1 Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs more "car-light" mobility options
- Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences

2 Task Objectives

Investing in an improved transit infrastructure will incur two types of costs:

- Capital Costs – the up-front costs of implementing a new or enhanced transit system
- Operations and Maintenance (O&M) Costs – the annual costs incurred after the system is active

This financial assessment identifies different capital and O&M funding options – focusing on opportunities to leverage available federal funds. The federal funds of most interest are those considered "discretionary," i.e., funds not otherwise available to New Hampshire for other purposes; the majority of discretionary federal funds are available to cover capital costs. Other types of federal dollars – formula funds – are available to pay for O&M.

Receipt of federal funds is subject to a variety of eligibility rules, and most federal funds must be "matched" (typically by 20 percent) by state and/or local funds. Given the match requirement, this

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

assessment also identifies potential state and local sources of funds that could provide this match. No recommendation on preferred sources of funds is made as part of this assessment. Rather, the options identified and evaluated will be subject to more discussion and decision-making once an alternative is identified as the preferred project for detailed development and ultimate implementation.

3 Non-Federal Transit Funding in the U.S.

As federal funds typically contribute a large share of transit project capital costs, this section describes how other state/local agencies across the country have paid for new transit projects.

3.1 Common Sources of State Funding

Most state transit funding comes from General Fund appropriations, or through traditional taxes and fees, such as motor fuel taxes, sales taxes, and vehicle fees. State transit funding provides both operating assistance and capital funds, but only a few states provide dedicated funding either for capital expenses (Arkansas, Idaho, Kentucky, and Nevada) or operating expenses (Maine, South Dakota, and Wisconsin).

3.2 Common Sources of Local Funding

Local transit funding is primarily provided through General Fund allocations, dedicated local option taxes and fees, and value capture mechanisms. Applying dedicated local taxes and value capture mechanisms for transit is dictated by enabling legislation that allows or restricts the use of these funding sources. Following is a description of common local funding options.

- **Sales taxes** are the most widely used source of dedicated transit funding. Sales tax rates typically range from 0.25 to 1.0 percent dedicated to transit, applied to purchased goods or services. Given the broad tax base of dedicated sales taxes, revenues can usually be applied to both capital and O&M expenses, and some agencies pledge sales tax revenues to support debt financing of major capital investments. Many bus rapid transit (BRT) and light rail transit (LRT) systems in the U.S. are funded through dedicated sales tax revenues.
- **Property taxes** are generally the principal source of revenue for local governments (with revenues going into the General Fund), but some states provide enabling legislation that allows property tax revenues to be dedicated to transit.
- **Motor fuel taxes** are generally levied as an excise tax (i.e., cents per gallon), although some local governments apply a sales tax on the price of fuel, with levies dedicated to transportation. Motor fuel tax revenues, however, are not a common local transit funding source, although they have been authorized and used by some transit agencies.
- **Vehicle fees** include registration fees, driver license fees, car rental taxes, and tolls not typically used for transit. In New Hampshire, any city or town can levy a registration fee of up to $5.00 for municipal transportation improvements, including transit capital and operating expenses.[2]

[2] New Hampshire Revised Statutes Annotated 261:153(VI)

- **Employer/payroll taxes** refer to taxes imposed directly on employers for the amount of gross payroll paid for services performed within a transit district. **Income taxes** are applied to individual earnings, but are less commonly applied at the local level.
- **Utility taxes/fees** are local utility charges to property for access to the transportation system, mainly used for local roads and streets. Transportation utility rates can be set using different measures, including fees that apply per unit of housing or parking space, fees based on square footage or gross floor area, and fees that vary with the trip generation rate of a given property type.
- **Room/occupancy taxes** are applied either as sales tax on the cost-per-room, or as a daily-fee-per-room, and are dedicated typically to tourism or tourism-related facilities. They may be implemented to support transportation investments where needed to enhance the visitor experience, mobility, and accessibility.
- **General revenues** (non-dedicated) refer to funding provided by local governments for transit services, whether through a jurisdiction's annual budget and appropriations process, grants/contributions, or negotiations or local agreements between the transit service provider and the jurisdiction(s) within the transit service area.
- **Value capture** mechanisms are special types of "property taxes" or fees targeted to capture the benefits or cost of infrastructure that serves property development. To date, this source, when used, typically contributes less than five percent of total project costs. Some of the most common value capture techniques are described below.

    - **Impact fees** are one-time charges to developers on new development. Revenues are typically used to pay infrastructure improvements required to meet the increase in demand generated by the new development.
    - **Tax Increment Financing (TIF)** districts are created to capture the increase in property tax levies over the base or expected future levies as a result of infrastructure improvements. The additional levies are typically pledged to bonds issued to finance infrastructure improvements.
    - **Special assessment districts** are created to levy additional property taxes dedicated to infrastructure improvements serving the district, with the approval of property owners.
    - **Joint development** involves a partnership between the transit agency and a private developer, commonly applied to Transit-Oriented Development (TOD) on land at or adjacent to transit stations.

3.3 Recent History in Commuter/Intercity Rail Funding

To provide context for understanding how a rail investment in the Capitol Corridor might be funded, information was assembled on eight new commuter or intercity rail systems that have opened in the U.S. over the past 15 years, as shown in Table 3.1.

Table 3.1: New Commuter Rail Systems in the U.S. and Primary Capital Funding Sources

System	Location	Year Opened	Length (mi)	Federal	State	Local General	Sales Tax	Other Local
Sounder Commuter Rail	Puget Sound, WA	2000	33	●			●	●
Rail Runner Express	Albuquerque, NM	2006	97		●			
Music City Star	Nashville, TN	2006	32	●	●	●		
FrontRunner	Salt Lake City, UT	2008	44				●	
Northstar Line	Minneapolis, MN	2009	40	●	●	●		●
Capital MetroRail	Austin, TX	2010	32				●	
Westside Express Service	Portland, OR	2009	15	●		●		
A-Train	Denton County, TX	2011	21				●	●

Capital funding for these projects comes from a variety of sources. The most common source, used in half of the projects, is Federal Transit Administration (FTA) Section 5309 New Starts funding, which accounted for an average 43 percent of these projects' capital costs. One project, the Rail Runner Express extending between Albuquerque and Santa Fe, was funded entirely through state bonds backed by state road and highway revenues, including gasoline and diesel fuel taxes and federal highway aid. Local funding was more diverse. Three systems used General Funds, mostly from local counties. Four projects used bonds backed by local sales taxes. Other local funding sources include a motor vehicle excise tax by Sounder Commuter Rail and road tolls, which paid for 80 percent of the A-Train capital costs. The Northstar Line in Minneapolis received a contribution from the Minnesota Twins major league baseball team, helping to fund the terminal station next to Target Field.

For operating costs, local sales taxes are the most common primary source, used by six of the eight new rail systems: Sounder Commuter Rail (Puget Sound, Washington), Rail Runner Express (Albuquerque, New Mexico), FrontRunner (Salt Lake City, Utah), Northstar Line (Minneapolis, Minnesota), Capital MetroRail (Austin, Texas), and A-Train (Denton County, Texas). The Westside Express Service in Portland, Oregon is primarily funded through a payroll tax. Operating costs for the Music City Star in Nashville, Tennessee are primarily funded through federal grants and contributions from Metro Nashville.

It is also useful to consider how other passenger rail projects in the Northeast have been funded, particularly projects that represent extensions of the Massachusetts Bay Transportation Authority's (MBTA's) system. For projects wholly located within the Commonwealth of Massachusetts, funding for extensions has been provided by a mix of state and federal sources:

- Extension of peak-period commuter rail service from Framingham to Worcester was completed in 1994, paid for by MBTA funds. Off-peak service was added in 1996, as well as infill stations in 2000 and 2002.
- The 27.6-mile Greenbush Line to Scituate was a state air quality commitment project that opened for service in 2007. The $534 million project was also paid for with MBTA funds.
- Half of the capital costs of improvements to the Fitchburg commuter rail line were paid for by an FTA Section 5309 Small Starts grant; the other half was paid for by state transportation bond proceeds. A 4.5 mile extension to a new Wachusett station was paid for by a U.S. Department of Transportation (USDOT) Transportation Investment Generating Economic Recovery (TIGER) grant (see Section 5.1.9). Construction is underway with completion expected in 2015.

Extensions of MBTA service south into Rhode Island have been implemented in accordance with the "Pilgrim Partnership," a 1989 cooperative agreement between the MBTA and Rhode Island Department of Transportation (RIDOT). These have included extension of MBTA commuter rail service to Providence, which was funded by RIDOT in part with "earmarks" in transportation appropriation bills (transportation earmarks have subsequently been prohibited by federal law) and state funds. In exchange for operation of the service by the MBTA, RIDOT suballocates its federal formula funds to the MBTA. Extension further south to Wickford Junction was paid for by an FTA Section 5309 Small Starts grant (50 percent of capital costs) and the remainder with a mixture of federal formula funds and state bonds. Intercity service between Portland, Maine and Boston (Amtrak *Downeaster*), restored in 2001 at a construction cost of approximately $66 million, was paid for by Congressional appropriations matched by state and local sources. Today, operation of the service is paid for through fares, which account for just under 50 percent of operating costs, federal funds (Congestion Mitigation and Air Quality Improvement Program, CMAQ, see Section 5.1.7) allocated to operations, an annual subsidy from Maine of approximately $8 million, and an in-kind contribution from Massachusetts consisting of trackage rights. New Hampshire, which has three *Downeaster* stations in Exeter, Durham at the University of New Hampshire, and Dover, does not contribute financially.

In all cases, both nationally and in the Northeast, state funding sources have been an integral part of each project's financial plan, including both construction and ongoing operations.

4 Funding Needs

This section identifies the capital and O&M costs needed to construct and operate the intermediate alternatives. Final capital costs were estimated in 2014 dollars, O&M costs in 2012 dollars.[3] To understand total needs to construct each alternative, capital costs were also escalated to year-of-expenditure dollars. For the rail alternatives, a four-year construction period is assumed, beginning in 2019.

For the Expanded Base alternative, capital costs consist of additional bus purchases. Some construction is associated with the two other bus alternatives to allow operation on the highway shoulder. It is assumed those construction activities could be accomplished over a three-year period.

The annual O&M costs for each alternative were also estimated based on costs for similar services provided elsewhere in New England or based on recent historic expenditures for similar services in New Hampshire.

Table 4.1 summarizes capital and O&M costs of six alternatives evaluated in detail in Appendix 7 to the Capitol Corridor AA Final Report; the No Build alternative is not shown, as this option does not incur capital costs and O&M costs remain unchanged.

Table 4.1: Capitol Corridor Alternatives' Capital and O&M Costs

Alternative	Capital Costs (In Millions, 2014$)		Annual O&M Costs (In Millions, 2012$)
	2014	Year-of-Expenditure Cost	
Manchester Regional Commuter Rail	$245.6	$303.4	$10.8
Nashua Minimum Commuter Rail	$120.3	$148.6	$4.1
Intercity 8	$256.5	$316.9	$7.7
Expanded Base	$9.6	$10.6	$3.0
Bus on Shoulder	$7.4	$8.4	$0.0
Expanded Bus on Shoulder	$17.0	$19.3	$3.0

Source: Jacobs Engineering, September 2014; bus O&M dollars reflect incremental costs of enhanced service or construction of a shoulder lane

[3] See Appendix 6 of Capitol Corridor AA Final Report (Task 6 Evaluation Criteria and Methodology, Appendix A Capital Cost Methodology Memo and B Operations and Maintenance Cost Methodology Memo)

5 Federal Funding Sources

This section describes federal funding sources that might be used to help pay for new transit service in the Capitol Corridor. A key objective of any Capitol Corridor Financial Plan is to leverage federal sources to the greatest extent possible.

5.1 Federal Funding Sources and Financing Tools

Within the USDOT, the FTA administers the primary funding programs available for public transportation investments. The Federal Highway Administration (FHWA) administers some federal-aid highway programs with flexible provisions that allow the transfer of funds for public transportation investments. The Federal Railroad Administration (FRA) administers the Railroad Rehabilitation and Improvement Financing (RRIF) program, which can be used for passenger rail projects, and in the past has provided capital funding through the High-Speed Intercity Passenger Rail (HSIPR) program.

In addition, federal finance tools are available that can be used to advance project implementation by leveraging future revenue streams of dedicated funding.

This section summarizes potential federal funding and financing tools and their eligibility to fund the proposed Capitol Corridor alternatives. Examples of other projects that have used these sources as part of their funding plan are identified. Table 5.1 provides a high-level summary of the federal funding sources and tools discussed in this section, including potential eligibility, based on proposed mode.

Table 5.1: Federal Funding Sources and Tools

Funding Source	Capital, O&M, Both	Eligible Mode	Formula/Competitive	Comments
FTA 5311(f) Intercity Bus	Both	Intercity Bus	Formula	
FTA 5309 Capital Investment Grant (CIG) (New and Small Starts) Program	Capital	Commuter Rail	Competitive	For New Starts projects, CIG share capped at roughly 50% of capital costs; for Small Starts, cap is $75 million
FTA 5307 Urbanized Area Formula Grants	Capital	Commuter Rail Intercity Bus	Formula	Formula amounts, calculated based on metrics that included fixed-guideway route and revenue vehicle miles, would increase following implementation of one of the commuter rail alternatives
FTA 5337 State of Good Repair (SGR) Grants	Capital	Commuter Rail	Formula	After seven years of rail implementation
FHWA National Highway Performance Program (NHPP)	Capital	Intercity Bus	Formula	Must benefit the National Highway System
FHWA Surface Transportation Program (STP)	Capital	Commuter Rail Intercity Bus	Formula	Flex
FHWA CMAQ	Both	Commuter Rail Intercity Rail Intercity Bus	Formula	Flex

Funding Source	Capital, O&M, Both	Eligible Mode	Formula/Competitive	Comments
FRA HSIPR	Capital	Intercity Rail	Competitive	No funding currently available
USDOT TIGER	Capital	Commuter Rail Intercity Rail	Competitive	No funding currently available; average award of $17.6 million for transit projects
USDOT Transportation Infrastructure Finance and Innovation Act (TIFIA)	Capital	Intercity Rail Commuter Rail Intercity Bus	Competitive	Loan Program
FRA RRIF	Capital	Intercity Rail Commuter Rail	Competitive	Loan Program

5.1.1 FTA Section 5311(f) – Intercity Bus

The FTA Rural and Small Urban Areas (Section 5311) funding program provides capital, operating, and administrative expense support in areas with a population under 50,000. Within this program, Section 5311(f) requires at least 15 percent of a state's funds to be used to support intercity bus services, unless the Governor has certified that such needs are already being met. This funding can be used for up to 80 percent of capital costs and 50 percent of net operating costs (after fare revenues are credited and ineligible costs are deducted). Under Section 5311(f), the following activities are eligible for funding:

- Operating assistance for direct operation of intercity service
- Operating grants through purchase-of-service agreements
- Capital grants for intercity vehicles and equipment, bus shelters, joint-use stops, and depots
- Planning and marketing for intercity bus transportation
- User-side subsidies
- Demonstration projects
- Coordination of rural connections between small public transportation operations and intercity bus carriers

New Hampshire received nearly $3.1 million in FTA Section 5311 funds for FY2014, of which $450,000 could be available for intercity bus. One recent 5311(f) grant awardee was the Concord Coach Lines, Inc., which received operating assistance totaling $153,549 to increase service frequency to Littleton and Conway.

5.1.2 FTA Capital Investment Grant Program (Section 5309) – New and Small Starts

The FTA Section 5309 CIG program is the primary funding source for major transit capital investments. Eligible projects include new fixed guideways or extensions to fixed guideways, bus rapid transit projects, and projects that improve capacity on an existing fixed-guideway system; the two commuter rail alternatives would be considered eligible projects under this program. This discretionary program requires project sponsors to undergo a multi-step, multi-year process to be eligible for funding. The capital costs of the proposed commuter rail alternatives for the Capitol Corridor range between $148.6 million and $303.4 million (year-of-expenditure). The lower cost alternative to Nashua falls within the Small Starts cost threshold, while the Manchester alternative would be defined as a New Start.

To be considered a Small Starts project, the total project cost in year-of-expenditures dollars must be under $250 million, and the Small Starts share must be less than $75 million. A New Starts project costs over $250 million, and the share of funds that would be provided from FTA would average roughly 50 percent of capital costs. The program is chronically oversubscribed and thus extremely competitive. As a result, whether a Small or New Starts, the Capitol Corridor project must demonstrate that it performs well according to FTA's project evaluation measures[4] and that it has strong local commitment – i.e., sufficient state and local non-federal matching funds – to earn a portion of this limited federal capital funding source.

5.1.3 FTA Urbanized Area Formula Grants (Section 5307)

The FTA Urbanized Area Formula Grant program provides grants for public transportation capital, planning, job access, and reverse commute projects, as well as operating expenses in certain circumstances (rail-fixed guideway projects are excluded from operating costs under this program). The funding formula is based on a combination of bus revenue vehicle miles, bus passenger miles, fixed-guideway revenue vehicle miles, and fixed-guideway route miles, as well as population, population density, and number of low-income individuals. Funding apportionments to New Hampshire for FY2013 totaled $6.5 million, of which $4.0 million are administered by the New Hampshire Department of Transportation (NHDOT) for Urbanized Areas (UZAs) of 50,000 to 200,000 population.

In addition to potential funding allocations for implementation of proposed commuter rail alternatives, FTA Urbanized Area formula apportionments to New Hampshire may increase roughly two years following the start of revenue service on the corridor. Based on FY2014 formula factors and the proposed incremental level-of-service for the commuter rail and bus alternatives, the additional FTA formula funds anticipated for New Hampshire are estimated at approximately $300,000 for the bus alternatives (Expanded Base and Expanded Bus on Shoulder) and between $700,000 and $2.5 million for commuter rail options. This additional funding could be reinvested in the corridor to address preventative maintenance and other capital needs.

5.1.4 FTA State of Good Repair Grants (Section 5337)

The FTA SGR program provides funding for capital projects to maintain, repair, and upgrade rail transit systems and high-intensity motor bus systems. It is a formula program, with grants allocated based in part on revenue vehicle miles and route miles. The program requires a 20 percent local match. Eligible recipients are state and local government authorities in urbanized areas with fixed-guideway public transportation facilities operating for at least seven years. Currently, New Hampshire is not an eligible recipient, but funding may become available seven years after the start-of-revenue service of fixed-guideway rail service, such as one of the commuter rail alternatives. The funds can be used for preventative maintenance and SGR activities. None of the other alternatives would be eligible for this source.

[4] FTA evaluates project justification according to several criteria: mobility improvements, cost effectiveness, transit supportive land use, economic impacts, and environmental benefits; congestion relief is an additional measure of project justification, although FTA has not yet determined a measurement approach for this criterion

5.1.5 FHWA National Highway Performance Program

The FHWA NHPP provides funding specifically to support the condition and performance of the National Highway System (NHS). While this is a highway-specific program, NHPP funds could be used on a public transportation project that supports progress toward achieving national performance goals for improving infrastructure condition, safety, mobility, or freight movement on the NHS, and meets the following criteria:

- Project is in the same corridor as, and in proximity to, a fully access-controlled NHS route
- Construction is more cost-effective (as determined by a benefit-cost analysis) than a NHS improvement
- Project will reduce delays or produce travel time savings on the NHS and improve regional traffic flow

Types of public transportation eligible projects may include the construction of publicly owned intracity or intercity bus terminals servicing the NHS.

5.1.6 FHWA Surface Transportation Program

The FHWA STP provides flexible funding to states for a variety of eligible activities, including many highway-related activities, as well as capital costs for transit projects, such as vehicles and facilities used to provide intercity passenger bus service. The program can fund capital for transit projects eligible for federal funding under Chapter 53 of Title 49, which could include the commuter rail and bus alternatives.

5.1.7 FHWA Congestion Mitigation and Air Quality Improvement Program

The FHWA CMAQ program funds transit system capital expansion and improvements projected to realize an increase in ridership, travel demand management strategies and shared ride services, and pedestrian and bicycle facilities. Projects must have a transportation focus, reduce air emissions, and be located in or benefit an air quality nonattainment or maintenance area. Funding is distributed based on a formula that considers the severity of air quality problems. The federal share is 80 percent for most CMAQ projects.

In FY2013, New Hampshire received $10.3 million in CMAQ funds. Using these funds for a project in the Capitol Corridor would require reallocation of some portion of the total New Hampshire apportionment. Under current rules, CMAQ funds can be used for the project's capital expenses, as well as operating costs, for a limited period of time. Operating assistance is limited to certain activities, including new transit, commuter, and intercity passenger rail services. Under the Moving Ahead for Progress in the 21st Century (MAP-21) Act, the operating funding period was extended from three to five years.

5.1.8 FRA Discretionary Programs

FRA occasionally makes funding available through discretionary programs that provide grants to eligible projects through a competitive application process. For example, the HSIPR was created to make investments in a network of passenger rail corridors across the country. The program's objectives are to

build new high-speed rail corridors, upgrade existing intercity passenger rail corridors, and lay the groundwork for future high-speed rail services through planning efforts. More than $10 billion in grant funding was provided after the enactment of the program through the Passenger Rail Investment and Improvement Act (PRIIA) of 2008, including a FY2010 grant of $2 million to the Capitol Corridor for engineering and environmental analysis. The program was highly competitive, with over $75 billion in total funding requests from 39 states, Washington D.C., and Amtrak. While the program is not currently funded and no new funding appears to be likely in the near-term (thus no applications are being accepted), the intercity rail alternative could be eligible for future grant solicitations should additional funding be allocated.

5.1.9 USDOT Transportation Investment Generating Economic Recovery

Another discretionary funding source is USDOT's TIGER program. Competitive grant applications are solicited on a periodic basis; there have been six rounds of funding since 2009, providing $4.1 billion to eligible road, rail, transit, and port projects. Rail and transit projects awarded TIGER funding have accounted for more than 40 percent of total awards to date. The average award for transit projects was $17.6 million. The last round of awards was announced in September 2014. Should another round of funding be made available, the commuter rail and intercity alternatives could be eligible projects.

5.1.10 USDOT Transportation Infrastructure Finance and Innovation Act Credit Assistance

The TIFIA program is a credit assistance program administered by USDOT providing direct loans, loan guarantees, and standby lines of credit. Surface transportation projects that cost $50 million or more are eligible, including those for state and local governments, transit agencies, railroad companies, special authorities, special districts, and private entities. Any transit project eligible for grant assistance under the transit title of the U.S. Code (chapter 53 of 49 U.S.C.) and intercity bus vehicles and facilities are eligible for TIFIA credit assistance. In addition, rail projects involving the design and construction of intercity passenger rail facilities or the procurement of intercity passenger rail vehicles are also eligible. The TIFIA loan or loan guarantee amount should not exceed 49 percent of eligible costs; for standby lines of credit, the limit is 33 percent of the project costs. Dedicated revenues for repayment are required. Tax revenues, including sales taxes, are a common revenue pledge for TIFIA. A total of $1.0 billion was authorized for this program in 2014.

5.1.11 FRA Railroad Rehabilitation and Improvement Financing Program

The RRIF is an FRA loan program enacted under the Transportation Equity Act for the 21st Century (TEA-21) that provides direct federal loans and loan guarantees to finance development of railroad infrastructure. Eligible applicants are railroads, state and local governments, government-sponsored authorities and corporations, joint ventures that include at least one railroad, and limited option freight shippers who intend to construct a new rail connection. Loans can cover up to 100 percent of project costs with interest rates equal to U.S. Treasury rates. The Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) made amendments to the program; no changes were included in MAP-21. There have been few RRIF loans: Out of $35 billion in authorized funds, only $1.7 billion in loans have been awarded through FY2012. Reasons for the program's underutilization include that unlike TIFIA, there is no federal subsidy; therefore, costs associated with

FRA's review of the RRIF loan application are covered by the applicants. In addition to this investigative fee, the applicant also pays a credit risk premium unless collateral is provided. Other issues include long loan processing times and the perception that applicants bear the full risk of default.

Eligible projects include acquisition, improvement, or rehabilitation of intermodal or rail equipment or facilities; refinancing existing debt incurred for the purposes above; or developing or establishing new intermodal or railroad facilities. The Northern New England Passenger Rail Authority (NNEPRA), which operates the *Downeaster* passenger rail service between Brunswick and Boston, was approved for a RRIF loan in 2009, but this was foregone in favor of HSIPR grant funding awarded for the project.

5.2 Non-Federal Match Options for Alternatives

Non-federal match options for a project implemented in the Capitol Corridor were narrowed from the longer list identified in Section 3.2, since some of the most commonly used sources of local funding for transit are not available in New Hampshire. These include dedicated sales tax revenues (which are the most common source of local match in the U.S.), payroll taxes, and fuel taxes.

- New Hampshire does not impose any sales or payroll taxes, and it is assumed they would not be implemented solely for a project in the Capitol Corridor.
- Fuel taxes are constitutionally restricted in New Hampshire for use on construction, reconstruction, and maintenance of public highways,[5] so a project in the Capitol Corridor would be ineligible for this funding source, and a change to the constitution is not perceived to be possible.

For each funding option discussed below and summarized in Table 5.2, a definition is first provided, followed by an assessment of the feasibility and potential revenue estimate for each source. Ratings for feasibility reflect an assessment of 1) whether the source currently exists in New Hampshire, 2) whether transit is an eligible expenditure for the funding source, 3) the extent of likely support for the source, and 4) actions (e.g., legislative) that would be required for use of the source as part of the project's financial plan to cover costs.

The amount of revenue that might be generated from each source also is estimated. All of these estimated yields are subject to change based on changes to input assumptions and charge rates. Annual yield rating ranges: estimates greater than $5 million = High; $1-$5 million = Medium; less than $1 million = Low.

In general, each feasible funding source requires significant effort and commitment to implement. As potential sources are evaluated, it will be important to consider the level of required effort in the context of likely yield. While revenue estimates are provided for all options, sources with low feasibility are unlikely to be available given significant implementation challenges.

[5] Part II, Article 6-a of the New Hampshire Constitution

Table 5.2: Summary of Non-Federal Funding Options for Capitol Corridor Alternatives

Funding Source	Feasibility	Yield	Annual Estimate (In Millions)	Comments
NH State Capital Program	High	High	$10.0	7.6% of 2014 debt payment (principal + interest)
NH Parking Fees	High	Low	$0.7	Based on $4.00 per day parking fee
Vehicle Registration Fees	Medium	High	$5.9	$5.00 fee on passenger vehicles and trucks statewide
Municipal Contribution	Medium	Medium	$1.0-3.0	$1 million/city with new stations; city discretion regarding source
Regional Greenhouse Gas Initiative (RGGI)	Medium	Low	$0.5	Based on historical awards
Property Tax	Low	High	$15.7	0.1 mill applied statewide
Lottery Revenues	Low	Medium	$3.7	5% of net proceeds
Passenger Facility Charges	Low	Medium	$1.0	½ of $1.50 passenger facility charge (PFC) increase beginning in 2016
Value Capture	Low	Low	--	Need more study to estimate

5.2.1 New Hampshire State Capital Program

New Hampshire State (Legislature/Governor) approves a capital budget every two years. The last approved budget, for 2014-2015, was $219.4 million (for all projects, including highways, which are paid for with restricted revenues, i.e., fuel tax and highway user fees). The next cycle to approve the budget is initiated in the fall (projects are submitted by November 15). The budget is approved on February 15th of odd numbered years (i.e., the next budget will be approved in February 2015).

The most recent budget included bond authority for the entire cost of the capital program ($219.4 million). Of this, $128.7 million are for projects funded with bonds that are repaid with unrestricted General Fund revenues.

For NHDOT, bonds for highway projects are repaid with highway revenues (restricted). The capital budget included $2.2 million in General Fund bonds for NHDOT's Aeronautics, Rail and Transit Division. The proceeds provide matching funds to Federal Aviation Administration (FAA) and FTA grants.

As of June 2013, the state had $963.2 million in outstanding general obligation debt, including bonds for highways and the University of New Hampshire.

Feasibility	Yield
▪ Existing source of funding for state capital investments through bonds repaid with unrestricted General Funds ▪ Currently providing matching funds to federal grants for NHDOT's Aeronautics, Rail and Transit Division ▪ Governor/Legislature support required ▪ Only for capital expenses	▪ Would need to assess feasibility of fully or partially providing Capitol Corridor project capital funding needs through the State Capital Program, while maintaining reasonable debt-to-state revenue ratios ▪ The largest single funding allocation from bond proceeds in recent years was for $38 million, which is less than 15 percent of total funding needed for most costly alternatives ▪ Assumes an annual allocation of $10 million in unrestricted General Funds to repay bonds issued through the capital budget to pay for construction of the selected alternative; at the current debt service level (FY2014 = $132.2 million), $10 million represents about 7.6 percent of unrestricted General Fund revenues required to repay bonds

5.2.2 Parking Fees

New parking facilities associated with the alternatives could generate funding to support O&M expenditures. Only the rail alternatives include planned new parking, so this potential revenue source is not available for the bus alternatives.

The methodology to estimate revenues is based on parking occupancy and the number of vehicles that use the parking facility in an average day. If most travel is work-related, chances are that most parking spaces are occupied by a single vehicle any given day, and the parking turnover rate would be low.

Feasibility	Yield
▪ Parking at rail stations will be provided, so parking would be considered a future available source for funding	▪ Based on data provided by Jacobs Engineering, an estimated 470 to 925 parking spaces would available at planned commuter and intercity rail park-and-ride lots, depending on the alternative; if fully occupied 240 days per year, with a per-day parking fee of $4.00, parking revenues would total between $0.5 million and $0.9 million annually; a midrange of parking yields $0.7 million annually; for comparison, most MBTA commuter rail park-and-ride facilities charge $4.00 per day; in Lowell, garage parking is priced at $5.00 per day

This fee could be extended to other park-and-ride facilities, specifically those used by riders of intercity bus service between New Hampshire and Boston.

5.2.3 Vehicle Registration Fees

New Hampshire currently collects vehicle registration fees at the state and local level that vary by type, size, value, and age of the vehicle. State fees are restricted to use on highways, but municipalities have more latitude on the use of at least a portion of their revenue.

Feasibility	Yield
▪ Changes to registration fees would require legislative action to modify Section 261:141 (Registration Fees)[6] and/or Section 261:153 (Municipal Permits for Registration)[7] of Title XXI (Motor Vehicles) in the state statutes ▪ State-level registration fees are constitutionally restricted to be used for construction and maintenance of public highways,[8] while local-level fees have a broader range of uses ▪ Fees are assumed to be applied statewide	▪ In 2011, nearly 840,000 passenger vehicle registrations and 334,000 truck registrations were processed in New Hampshire;[9] assuming a $5.00 fee statewide translates to approximately $5.9 million annually ▪ This yield assumes a small statewide increase; other assumptions could be made, including geographies covered – i.e., only the municipalities served by the project in the Capitol Corridor – and fee rates

[6] http://www.gencourt.state.nh.us/rsa/html/XXI/261/261-141.htm
[7] http://www.gencourt.state.nh.us/rsa/html/XXI/261/261-153.htm
[8] Part II, Article 6-a of the New Hampshire Constitution
[9] https://www.nh.gov/safety/documents/2011-annual-report.pdf

5.2.4 Municipal Contributions

Cities often help pay for implementation and/or ongoing O&M of transit projects, particularly cities that receive a substantial new station that generates accessibility benefits and increases in development opportunities and property values. For this assessment, it is assumed that only cities that will have rail stations – Nashua, Manchester, and Concord, depending on the alternative – could make an annual contribution.

Feasibility	***Yield***
▪ Cities would have the flexibility to identify their own sources of revenue, whether an existing source or a new source associated more directly with the project, such as a tax increment financing district or some other value capture mechanism	▪ For purposes of this assessment, it is assumed that Nashua, Manchester, and Concord would contribute (e.g., $1 million annually) depending on the alternative/whether it includes a rail station in the municipality

5.2.5 Regional Greenhouse Gas Initiative (RGGI)

Proceeds from the auction of RGGI emissions allowances in New Hampshire go to the Greenhouse Gas Emissions Reduction (GHGER) Fund. Ten percent of funds are set aside for a low-income residential energy reduction program; the remainder is awarded in grants through a Request for Proposal (RFP) process focused on electric and fossil fuel energy efficiency programs. A list of eligible programs includes nothing transportation-related, only buildings, although the list indicates eligibility is not limited to that list.[10]

As of 2013, New Hampshire had received more than $57 million in allowance auction revenues over five years.[11] Grant awards have ranged from as little as $8,000 to as much as $5 million.

No New Hampshire transportation project has yet been awarded grants from the GHGER Fund. In the 10 states participating in RGGI, one percent of CO_2 allowance proceeds have been used "for a wide variety of greenhouse gas reduction programs, including programs to promote the development of carbon emission abatement technologies, efforts to reduce vehicle miles traveled, and programs to increase carbon sequestration." Therefore, there is some precedent in at least one of these states to use these funds for a transportation project.

[10] https://www.puc.nh.gov/SustainableEnergy/GHGERF.htm
[11] http://www.rggi.org/docs/Investment_of_RGGI_Allowance_Proceeds.pdf

Feasibility	Yield
▪ Use of RGGI proceeds for transit improvements in the Capitol Corridor would need to be confirmed	▪ For the purposes of this assessment, it is assumed that a project in the Capitol Corridor could receive annual grants of the same order of magnitude of historical grant awards through this program, or approximately one-half million per year

5.2.6 Property Tax

Four types of property taxes are assessed in New Hampshire: town tax, local education tax, state education tax, and county tax. Property taxes are a common source of funding for transit projects in the U.S.

Feasibility	Yield
▪ Major existing local source of revenue ▪ Currently, all state-levied property taxes are dedicated to education; using this revenue source for the Capitol Corridor would require legislative action	▪ In 2012, total assessed property value in New Hampshire was $156.6 billion;[12] the weighted statewide average of property tax rates was 20.71 mill ▪ Applying a tax rate of 0.1 mill (10 cents per $1,000 in assessed value) would generate approximately $15.7 million per year

5.2.7 Lottery Revenues

New Hampshire has the oldest legal lottery in the U.S. The state participates or hosts a variety of lottery games, including scratch tickets and draw games.

Feasibility	Yield
▪ Currently, all net lottery revenues in New Hampshire are dedicated to the state education fund ▪ A new lottery game dedicated to the Capitol Corridor or more broadly for transportation use would likely be needed, rather than diverting revenues from existing games; in either case, legislative action would be required	▪ Lottery revenues in New Hampshire, net of prizes and administrative expenses, totaled $74.3 million in 2013 ▪ Five percent applied to a Corridor project would result in $3.7 million per year

[12] New Hampshire Department of Revenue Administration

5.2.8 *Passenger Facility Charges*

Manchester-Boston Regional Airport (Manchester Airport) currently collects the maximum $4.50 per enplanement passenger facility charge (PFC). Eligible projects include those improvements related to enhancing airport safety, capacity, security, and environmental concerns. Under its current approvals, the airport is authorized to collect PFC through November 2022.

In the near-term, PFC revenues at the $4.50 level are fully committed, including payments to debt service on outstanding bonds, approved pay-as-you-go projects for which the airport has not yet reimbursed itself, and additional projects identified in the Capital Improvement Program.

Feasibility	***Yield***
▪ In the current FAA reauthorization proposals, the cap on PFC levels may be raised beyond the $4.50 level to provide additional funding available outside of FAA's Airport Improvement Program (AIP); beginning in FY2016, the airport is assumed to increase its PFC level to $6.00 and additional collections are assumed to be used on a pay-as-you-go basis for future projects[13] ▪ It appears possible, but difficult, for a transit project to use this funding source given restrictions on project eligibility and the existing cap on PFC levels; if an eligible project could be developed, negotiations would be needed with the airport and FAA to include it in the airport's future capital plan	▪ Enplanements have fallen since their 2.2 million peak in 2006, and totaled 1.36 million in 2011;[14] an additional $1.50 PFC would create an estimated $2 million annually; if half of this increment could be directed towards a corridor project, then this would provide $1 million annually to the project pending eligibility considerations

5.2.9 *Value Capture*

Value capture includes revenue mechanisms such as impact fees, TIF, and special assessment districts. Without specifics on future development and potential development to result from implementation of new transit corridor service, it is difficult to generate estimates for impact fees or TIF. An option is to estimate how much revenue could be generated through a special assessment district. Data needs/basic assumptions for special assessment district example include the following:

[13] http://www.flymanchester.com/sites/default/files/public-documents/ManchesterAirportMasterPlanUpdate.pdf
[14] http://www.flymanchester.com/sites/default/files/statistics/MHTEnplanements2000-2012.pdf

- Taxable property values in the cities/towns served by each corridor alternative (New Hampshire Department of Revenue) or within some agreed upon distance from the corridor and/or station locations
- Historical trends on property value growth
- Property tax rate
- Alternatively, calculate tax rate, based on capital and O&M needs

It should be noted that changes in development patterns and property values take time – often considerable time – to be realized based in large part on market conditions and demand. Therefore, value capture would not be a near-term source of revenue for a Capitol Corridor project.

5.3 Massachusetts Department of Transportation (MassDOT)/MBTA Contributions for Commuter Rail Alternatives

An additional source of funding for the two commuter rail alternatives (Manchester Regional and Nashua Minimum) could be the MassDOT/MBTA. NHDOT has had discussions with officials from these organizations about cost sharing arrangements for alternatives that extend the MBTA's existing Lowell Line into New Hampshire. Based on these discussions, the following contributions might be considered as part of one of the commuter rail alternative's financial plan:

- MassDOT/MBTA owns the corridor rail line to the New Hampshire/Massachusetts border. North of the border, the line is owned and operated by PAR. The MBTA recently acquired trackage rights for commuter rail service on the PAR line north to Concord in exchange for other considerations worth approximately $35 million. On a prorated basis, the roughly 20 miles to Manchester would be valued at $18 million for the Manchester Regional Commuter Rail alternative. This could represent a source of non-federal match donated by the MBTA. The value of the MBTA trackage rights used for the Nashua Minimum Commuter Rail alternative would be less than $1 million since the service extends less than a mile into New Hampshire.
- Construction of infrastructure improvements in Massachusetts could be paid for by MassDOT. The extent of these infrastructure improvements is from Lowell Station (Milepost 25.4) to the Massachusetts/New Hampshire state line (Milepost 34.4). The costs of these infrastructure improvements in Massachusetts, which would be incurred for both commuter rail alternatives, are estimated at $45.5 million in 2014 dollars.
- Rolling stock for both commuter rail alternatives would be provided by MBTA. The value of that rolling stock could be considered as a project cost to be paid for by MBTA and count towards the non-federal local match. For the Manchester Regional Commuter Rail alternative, rolling stock is valued at $33.2 million and for the Nashua Minimum Commuter Rail alternative at $20.5 million.

Totaled together, and assuming contributions at the levels suggested above, nearly 40 percent of the capital costs of the Manchester Regional Commuter Rail alternative and 55 percent of the Nashua Minimum Commuter Rail alternative could be paid for by MassDOT/MBTA.

5.4 Fares

Each alternative's O&M costs will be partly offset by fares collected from riders. Table 5.3 provides the total annual fare revenue estimated for each alternative, as well as the farebox recovery ratio (percentage of annual O&M costs covered by fares). As shown, the Manchester Regional Commuter Rail alternative has a very high recovery ratio, since trips made on this alternative represent the highest value fares along the entire line.

Table 5.3: Annual Fare Revenue, O&M Cost, and Farebox Recovery Ratio by Alternative

Alternative	Fare Revenue (In Millions, 2014$)	Incremental Annual O&M Cost (In Millions, 2014$)	Farebox Recovery Ratio
Manchester Regional Commuter Rail	$6.9	$10.8	64%
Nashua Minimum Commuter Rail	$1.8	$4.1	44%
Intercity 8	$3.2	$7.7	41%
Expanded Base	$0.8	$3.0	25%
Bus on Shoulder	$0.1	$0.0	0%
Expanded Bus on Shoulder	$0.9	$3.0	28%

5.5 Summary

While final decisions on a preferred alternative for advancement will necessarily incorporate a broad range of considerations including benefits and impacts, the ability to identify stable and reliable sources of revenue will be critical to the advancement of any alternative. Leveraging available discretionary federal funds is a key objective of a future funding plan. In addition, there might be some limited opportunities for project delivery through some form of Public Private Partnership (PPP), which may be investigated as alternatives are refined.

This section summarizes key findings regarding federal fund leverage potential by alternative. Some suggestions also are provided on other sources of potential revenue to provide a match for federal funds; however, any new source of revenue to help pay for a transit investment in the Capitol Corridor will be subject to considerable review and input by corridor stakeholders and decision-makers.

- **Manchester Regional Commuter Rail** would be a candidate for New Starts funding established under FTA's CIG program. Eligible New Starts projects that meet certain criteria receive on average 50 percent of their capital costs. The remaining costs could be covered by other federal funding programs, such as CMAQ, as well as parking revenue and contributions from MBTA (track work and trackage rights, rolling stock) and the municipalities that will have commuter rail stations (Nashua, Bedford [Manchester Airport], and Manchester).
- **Nashua Minimum Commuter Rail** would be a candidate for Small Starts funding established under FTA's CIG program. Eligible Small Starts projects that meet certain criteria receive up to $75 million of their capital costs. The remaining costs could be covered by other federal funding programs, such as CMAQ, as well as parking revenue and contributions from the MBTA (track work, rolling stock) and from Nashua.

- **Intercity 8** would rely on federal programs, namely FRA's HSIPR. However, the HSIPR currently has no funding available. For purposes of this assessment, it is assumed that half the capital costs of the project might be paid for by a future HSIPR appropriation. Similar to the two commuter rail alternatives, local sources could include CMAQ and TIGER grants, parking revenue, and contributions for the three municipalities with stations (Nashua, Manchester, and Concord).
- None of the **three bus alternatives** require significant new capital investment, with estimates for new buses and infrastructure improvements ranging from $6.0 million to $13.4 million. The capital required likely could be covered by federal formula programs such as Section 5307 or CMAQ. Other new revenue sources are unlikely, given the limited additional mobility and economic benefits anticipated by increasing or otherwise enhancing existing bus service.

Table 5.4 shows a summary of how well each alternative might leverage discretionary federal funds – new dollars going to New Hampshire that would not otherwise be available, awarded based on a competitive process. The table also estimates total funding that might be provided by Massachusetts for the two commuter rail alternatives and Bus on Shoulder alternatives. Also provided is a preliminary estimate of remaining costs that would then need to be paid for with New Hampshire sources yet to be identified.

To help understand what this might mean in terms of an annual "bill" to New Hampshire for each alternative, debt service is calculated for the New Hampshire share of capital costs for rail options as well as for annual capital lease payments for bus alternatives. This annual debt service, which lasts only for the period of the bonds issued, is then added to the annual operating cost for each alternative, net of fares and incremental FTA Section 5307 Formula fund apportionments due to the new or increased level of transit services. The annual debt service must be viewed as a best case, since agreements with Massachusetts on cost sharing are subject to additional discussion and negotiation. Short-term financing costs during the construction period associated with the issuance of Grant Anticipation Notes (GANs) in advance of receipt of federal (FTA or FRA) discretionary funds are shown in Table 5.5.

All numbers are subject to change as additional work and coordination with potential funding partners is advanced.

Table 5.4: Possible Financial Assessment Summary (In Millions, 2014$)

Funding Source	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
NH Contribution to Infrastructure Cost	$149.0	$53.4	$233.2	$0.0	$0.0	$0.0
MA Contribution to Infrastructure Cost	$45.5	$45.5	$0.0	$0.0	$7.4	$7.4
Rolling Stock Value	$33.2	$20.5	$23.3	$9.6	$0.0	$9.6
Trackage Rights Value	$18.0	$0.9	$0.0	$0.0	$0.0	$0.0
Total Project Value	**$245.6**	**$120.3**	**$256.5**	**$9.6**	**$7.4**	**$17.0**
Potential Federal Grant	$122.8	$53.4	$128.2	$0.0	$0.0	$0.0
MA Share (MA Infrastructure, Rolling Stock – commuter rail only, Trackage)	$96.6	$66.9	$0.0	$0.0	$7.4	$7.4
NH Share (after Federal/MA contributions)	**$26.2**	**$0.0**	**$128.2**	**$9.6**	**$0.0**	**$9.6**
Annual Payment to Retire NH Share [a]	$2.1	$0.0	$10.3	$1.2	$0.0	$1.2
Annual Operating Cost	$10.8	$4.1	$7.7	$3.0	$0.0	$3.0
Annual Passenger Revenue	$6.9	$1.8	$3.2	$0.8	$0.1	$0.9
Incremental FTA Section 5307 Formula funds	$2.5	$0.7	$0.0	$0.3	$0.0	$0.3
Annual NH Cost for Service	**$3.5**	**$1.6**	**$14.8**	**$3.2**	**$0.0**	**$3.1**

[a] Assumes 20-year bonds (level payment) at five percent to retire the state/local match for commuter and intercity rail alternatives; for the bus alternatives, it is assumed that short-term debt/certificates of participation (COPs) will be issued to cover state/local costs; the minimum repayment period was assumed at nine years, or 75% of the useful life of buses, in line with FTA requirements for capital leases (http://www.fta.dot.gov/grants/12865.html)

Table 5.5: New Hampshire Cost of Financing GANs during Construction (In Millions, 2014$)

Funding Source	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
Short-term financing to advance federal grants	$2.3	$1.0	$2.4	$0.0	$0.0	$0.0

Short-term financing to cover lags in the federal reimbursement process during construction only accounts for interest payments (at three percent) over the four-year construction period, assuming level principal payments

1 Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs more "car-light" mobility options
- Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences

2 Task Objectives

This report summarizes the initial conceptual (preliminary) transit and intercity rail alternatives, which were developed to accomplish five objectives:

1. Address key transportation and related issues identified in the Study's purpose and need
2. Provide commuter bus (Boston Express, BX), commuter rail (Massachusetts Bay Transportation Authority, MBTA), and intercity rail (possibly Amtrak) service and operating plans, to accommodate Federal Transit Administration (FTA) and Federal Railroad Administration (FRA) Study funding sources
3. Develop plans with alternative northern terminus stations in Nashua, Manchester, and Concord
4. Develop a range of service levels (train and/or bus frequencies)
5. Develop a range of capital and operating costs and benefits

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

Appendices A and B to this report describe the methodologies used to develop preliminary capital and operations and maintenance (O&M) costs for the initial conceptual alternatives. Using these estimates, decision-makers will select the most promising alternatives for detailed evaluation (see Task 5/Appendix 5 to the AA Final Report). Following that in-depth evaluation, officials will be able to select an investment strategy.

2.1 Initial Conceptual Alternatives

2.1.1 Commuter Rail

Capital costs – including locomotives and passenger cars, track and signal improvements, and stations – range from $124 to $226 million; annual operating costs range from $5.2 to $13.3 million (see Table 2.1). Although no decision has been made on an operator, MBTA is a likely operator.

Table 2.1: Capital and O&M Costs for Preliminary Commuter Rail Alternatives

Alternative	Daily Rail Service	Capital Cost (In Millions, 2014$)	Annual O&M Cost (In Millions, 2009$)
Concord Regional	8 trains (4 round trips) to Concord and Manchester 30 trains to Nashua	$226	$11.1
Concord Commuter	18 trains to Concord 22 trains to Manchester 26 trains to Nashua	$206	$13.3
Manchester Regional	16 trains to Manchester 34 trains to Nashua	$164	$9.7
Manchester Commuter	20 trains to Manchester 30 trains to Nashua	$164	$9.9
Nashua Commuter	34 trains to Nashua only	$124	$6.8
Nashua Minimum	16 trains to Nashua only	$124	$5.2

2.1.2 Intercity Rail

Capital costs range from $162 to $174 million; annual operating costs from $7.7 to $17.3 million. No decision has been made on an operator (see Table 2.2).

Table 2.2: Capital and O&M Costs for Preliminary Intercity Rail Alternatives

Alternative	Daily Rail Service	Capital Cost (In Millions, 2014$)	Annual O&M Cost (In Millions, 2012$)
Intercity 18	18 trains (9 round trips) to Nashua, Manchester, and Concord	$174	$17.3
Intercity 12	12 daily trains to Nashua, Manchester, and Concord	$174	$11.6
Intercity 8	8 trains to Nashua, Manchester, and Concord	$162	$7.7

2.1.3 Express Bus Only

Capital costs range from $2 to $9 million; annual incremental operating costs from $0 to $3 million (see Table 2.3). BX currently provides commuter bus service within the corridor and would likely be the operator of this service.

Table 2.3: Capital and O&M Costs for Express Bus Alternatives

Alternative	Bus Service	Capital Cost (In Millions, 2014$)	Annual Incremental O&M Cost (In Millions, 2012$)
Base (Existing Bus Service)	Total buses (inbound/outbound) Manchester 18 N. Londonderry (Exit 5) 46 Londonderry (Exit 4) 17 Salem (Exit 2) 39 Nashua (Exit 8) 24 Tyngsborough (Exit 35) 23 South Station 80 Logan Airport 58	$0	$0
Expanded Base	Total buses (inbound/outbound) Manchester 32 N. Londonderry (Exit 5) 40 Londonderry (Exit 4) 39 Salem (Exit 2) 40 Nashua (Exit 8) 38 Tyngsborough (Exit 35) 38 South Station 120 Logan Airport 120	$6.4	$3
Bus on Shoulder (in Massachusetts only) on I-93 south of I-495	Total buses (inbound/outbound) Manchester 18 N. Londonderry (Exit 5) 46 Londonderry (Exit 4) 17 Salem (Exit 2) 39 Nashua (Exit 8) 24 Tyngsborough (Exit 35) 23 South Station 80 Logan Airport 58	$2.2	$0
Expanded Bus on Shoulder	Total buses (inbound/outbound) Manchester 32 N. Londonderry (Exit 5) 40 Londonderry (Exit 4) 39 Salem (Exit 2) 40 Nashua (Exit 8) 38 Tyngsborough (Exit 35) 38 South Station 120 Logan Airport 120	$8.6	$3

2.2 Next Steps: Alternative Evaluation and Screening

A "No-Build" scenario is also an alternative. Each alternative will be evaluated in Task 5/Appendix 5 to the AA Final Report against the following criteria:

- Costs (capital and operating)
- Ridership (total and by station)
- Land Use and Economic Development Impacts
- Environmental Fatal Flaws (including environmental justice)
- Likelihood of Qualifying for Federal Funding

Based on that evaluation, the number of alternatives will be reduced, and the most promising ones subjected to more detailed evaluation (Appendix 7 to the AA Final Report).

Appendix A
Preliminary Capital Cost Methodology Memorandum

TECHNICAL MEMORANDUM

This memorandum describes the assumptions and methods applied to derive preliminary capital cost estimates for the Capitol Corridor Alternatives Analysis (AA) Study. The Study team's approach to estimating capital costs was different for rail and bus service options. Each of the two approaches is described below.

Commuter Rail – A conceptual schedule was prepared for each rail service option. During the schedule design process, efforts were applied to limit the number of locations where meets between northbound and southbound passenger trains would occur. This, in turn, limits the extent of double track that would be required for each option. Schedules were also designed to minimize impacts on existing passenger rail services and to provide windows for through and local freight operations north of Lowell. Based on that analysis and information on the existing track configuration, the Study team determined the extent of additional infrastructure that would be required to operate each service option. Rail stakeholders that currently use some or all of the line and/or could operate the proposed services (including the Massachusetts Bay Transportation Authority, MBTA, Pan Am Railways [PAR], and Amtrak) were briefed on the service designs and infrastructure proposals.

Feedback from MBTA, PAR, and Amtrak was applied to finalize the infrastructure requirements for each of the nine preliminary rail options. Schematic track diagrams showing crossovers, turnouts, stations, and new tracks were prepared for each option (see Appendices A-1 and B-1 to this memorandum). Approximate capital cost estimates sufficient for a screening of preliminary alternatives were prepared based on those diagrams and using the assumptions and cost drivers summarized in Table A.1.

One key source for cost elements and unit cost estimates came from similar work on the same corridor prepared for the Nashua Regional Planning Council (NRPC) in 2005. Figures from this source were updated at four percent per year to account for inflation. Where costs from the earlier project were missing or questionable, Study team engineers drew on their recent experience working for and with MBTA on passenger rail renewal projects, including work on the Fitchburg Main Line, the Boston and Albany Line, and the new Cape Flyer Service. Estimates of direct costs were subject to various multipliers, management costs, and contingency allowances as summarized in Table A.2.

Table A.1: Key Cost Drivers, Assumptions, Unit Costs (2014$), and Sources

Cost Driver	Assumptions	Units	Unit Costs	Source
New Track to MBTA Standard	132#, Pandrol	Track Miles	$1,372,800	NRPC Passenger Rail Study
New Track to PAR Standard	132#, Cut spikes	Track Miles	$1,056,000	NRPC Passenger Rail Study
Replace Worn Rail (MBTA)	132#, Pandrol	Track Miles	$652,081	NRPC Passenger Rail Study
Replace Worn Rail (PAR)	132#, Cut spikes	Track Miles	$545,356	NRPC Passenger Rail Study
Tie Replacement (1/3rd)	3250 ties per mile	Ties	$106	NRPC Passenger Rail Study
Cut and Chip Brush on ROW	Northern Branch	Route Miles	$20,925	NRPC Passenger Rail Study
Reestablish Ditches on ROW	Northern Branch	Route Miles	$39,600	NRPC Passenger Rail Study
Shoulder Ballast Cleaning	Northern Branch	Route Miles	$39,930	NRPC Passenger Rail Study
New or Replaced Turnout		Each	$125,000	Recent MBTA projects
New or Replaced Crossover		Each	$250,000	Recent MBTA projects
Passenger Stations		Each	$10,000,000	Recent MBTA projects
Rolling Stock Layover Facility		Each	$13,950,000	Recent MBTA projects
Renew Grade Crossing Panels	Replace all	Grade Xing	$109,050	NRPC Passenger Rail Study
New AHCW Devices	Keep where extant	Grade Xing	$150,000	Recent MBTA projects
Relocate Fiber Optic Lines	Where necessary	Route Miles	$150,000	Recent MBTA projects
PTC Wayside Devices		Track Miles	$121,000	FRA documentation
Signal Upgrades	Where necessary			NRPC Passenger Rail Study

Table A.2: Multipliers, Management, and Contingency Factors

Bridge, culvert and retaining wall work	10% of direct cost
Environmental (soil disposal, noise abatement, solar, LEED)	3% of direct costs
Final design and construction phase services	12% of direct cost
Land acquisition	3% of direct cost
Railroad project management and construction management	3% of direct cost
Maintenance and protection of railroad (180 to 420 days depending on physical scope)	$2,000 per day (2014$)
Railroad flagging support (180 to 420 days depending on physical scope)	$2,000 per day (2014$)
Contingency	20% of total costs

During the preliminary screening of alternatives, the New Hampshire Department of Transportation (NHDOT) assumed that costs for developing stations at in Nashua, Manchester, and Concord would be local municipal expenses and were excluded from the project costs for screening purposes. (This assumption was reversed in developing final cost estimates based on feedback from stakeholders and elected officials.) The resulting estimates of overall infrastructure costs as applied to the preliminary screening of commuter rail options are shown in Table A.3.

Table A.3: Preliminary Capital Cost Estimates for Commuter Rail Options (In Millions, 2014$)

Service Option	From MP	To MP	Route Miles	Track	Stations	Signal	Layover	Allowances	Contingency	Total
Concord Regional	25.4	73.5	48.1	$51	$20	$34	$28	$37	$56	**$226**
Concord Commuter	25.4	73.5	48.1	$51	$20	$31	$14	$37	$53	**$206**
Manchester Regional	25.4	55.7	30.3	$37	$20	$24	$14	$27	$43	**$164**
Manchester Commuter	25.4	55.7	30.3	$37	$20	$24	$14	$27	$43	**$164**
Nashua Commuter	25.4	38.9	13.5	$24	$10	$20	$14	$24	$32	**$124**
Nashua Minimum	25.4	35.2	9.8	$24	$10	$20	$14	$24	$32	**$124**

Costs for commuter rail rolling stock were excluded from the preliminary commuter rail estimates because MBTA indicated they were in the process of receiving a substantial number of new locomotives and coaches that would render a large fraction of the current fleet as surplus. Massachusetts Department of Transportation (MassDOT)/MBTA indicated that MBTA would be able to supply the necessary rolling stock from this surplus equipment should New Hampshire and Massachusetts advance the project in the near future. The additional locomotive and coaches that would be required for each preliminary commuter rail option was valued at $28 million.

Intercity Rail – Preliminary intercity (Amtrak) capital costs (see Table A.4) were estimated using a methodology similar to the commuter rail methodology, but with assumptions for less double track and fewer stations. Schematic track diagrams showing crossovers, turnouts, stations, and new tracks were prepared for each option (see Appendix B-1 to this memorandum). Cost of rolling stock was included in the intercity options, as Amtrak indicated they could not operate the new service from within their existing fleet. The principal difference in costs between the options corresponds to fleet requirements necessary for each different level of service. An eight-train-per-day service could be operated with one train set sharing spares with the existing *Downeaster* service; the more extensive services would require an additional train set and more spare equipment.

Table A.4: Preliminary Capital Cost Estimates for Intercity Rail Options (In Millions, 2014$)

Service Option	Infrastructure Upgrades	Rolling Stock	Total
Intercity 8	$144	$18	**$162**
Intercity 12	$144	$30	**$174**
Intercity 18	$144	$30	**$174**

Bus – Preliminary estimates of capital costs for the bus options were driven by two factors: the additional buses required to operate more frequent service and the roadway upgrades that would be required to allow for bus on shoulder operations, which would provide more reliable peak service for some options.

The Expanded Base and Expanded Bus on Shoulder options entailed increasing the frequency of bus service. Additional vehicles would be required to operate the proposed services and both NHDOT and Boston Express (BX) indicated that new vehicles would be expected to cost $400,000 each. The Study team estimated the number of additional buses that would be required by consulting with NHDOT and BX to determine the size and utilization of the current BX fleet. Study team analysis indicated that amending the current schedule of peak service to operate direct non-stop half-hourly peak service from all six park-and-ride lots currently served by BX would require 16 additional buses be added to the current BX fleet of 22 vehicles (see Table A.5).

Table A.5: Boston Express Vehicle Requirements by Service Option

	Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
Vehicles to Operate Minimum Service	16	30	16	30
Fleet	22	38	22	378
Spares	6	8	6	8
Percent Spare	27%	21%	27%	21%

The Bus on Shoulder and Expanded Bus on Shoulder options entailed providing more reliable service by allowing buses to operate within highway shoulders during peak periods to bypass congestion in the general travel lanes. Study team analysis of existing and forecast traffic conditions found that Bus on Shoulder operations could reduce bus delays on I-93 south of I-495. This assumption was also made by the Merrimack Valley Regional Planning Commission in their 2014 Study on Bus Use of Shoulders. Analysis of existing right-of-way conditions found sufficient shoulder width on I-93 between I-495 and Somerville to allow Bus on Shoulder operation without substantial investment in new right-of-way. An allowance of $100,000 per route mile[2] (based on experience in Minnesota) was included for upgrades to drainage, striping, and signage that would be required for each of the 22 affected route miles. A more recent estimate of $250,000 per route mile[3] (2007) was used for final screening and analysis. Table A.6 shows the preliminary capital cost estimates for the bus options.

Appendix B
Preliminary O&M Cost Methodology Memorandum

TECHNICAL MEMORANDUM

This memorandum describes the assumptions and methods that were applied to derive the preliminary O&M cost estimates. The Study team's approach for estimating O&M costs was different for the commuter rail, intercity rail, commuter bus, and feeder bus service components. Each approach is described below.

Commuter Rail – A conceptual schedule was prepared for each rail service option. Each schedule included estimates of weekday train miles and estimates of rolling stock that would need to be added to the MBTA fleet for each service. A plan for track improvements to support each service option was prepared, allowing the team to assign a number of track miles to each service option. MassDOT and MBTA, rail stakeholders that would operate the proposed services, were briefed on the service designs and infrastructure proposals. Copies of the briefing documents with service statistics are found in Appendix A-1 to this memorandum.

Feedback from MassDOT and MBTA was applied to finalize the service designs and infrastructure requirements for each of the nine preliminary rail options. Those designs were used to prepare rough O&M cost estimates to a level sufficient for screening preliminary alternatives. The assumptions and cost drivers used to develop the estimates are summarized below.

MBTA cost reports to the FTA from 2009 were used to estimate components of cost for current MBTA service. Detailed operating information on MBTA's commuter rail service is limited because it is operated by a private contractor that is not required to disclose limited financial information for competitive reasons. Total annual costs for operations, mechanical (revenue vehicle) maintenance, and infrastructure (non-vehicle) maintenance are reported along with basic service statistics relating to transit service, fleet size, and infrastructure components. The Study team was able to disaggregate that basic information on MBTA commuter rail costs into four broad categories with allocation factors for each:

1. **Operations** – train and engine crews, train fuel, train dispatchers, crew callers, supervision, and train supplies; allocated by train mile
2. **Infrastructure maintenance** – inspection and maintenance of track, signals, stations, and structures, including non-revenue vehicles; allocated by track mile
3. **Mechanical maintenance** – inspection and maintenance of locomotives and coaches; allocated by vehicles in fleet; locomotives and coaches are estimated separately assuming that each locomotive requires four times more maintenance attention than the typical coach
4. **Administration** – human resources, information technology, safety, marketing, revenue management, and other central office oversight and support functions; it was presumed for the relatively small extension of the MBTA network into New Hampshire that cost impacts on MBTA administration would be negligible

Based on previous work with MBTA and other agencies, the Study team assumed that 15 percent of costs for operations, mechanical, and infrastructure were fixed overhead activities related to central office functions such as crew scheduling, mechanical facilities, and engineering management. Eighty-five percent of the average costs per train mile, locomotive, coach, and track mile shown in Table B.1 were used to estimate variable costs associated with the proposed service extension.

Table B.1: Derivation of Preliminary Estimates of Commuter Rail Operating Costs (2009$)

	Reported Annual Cost	Units	Reported Quantity	Ratio	% Variable	Variable Cost Ratio
Operations	$99,766,101	Train Miles	4,113,978	$24.25	85%	$20.61
Mechanical	$79,580,205	Peak Vehicles	418	$190,383.27	85%	$161,826
Locomotive Maint.	$31,938,544	Locomotives	60	$532,309	85%	$452,463
Coach Maintenance	$47,641,661	Coaches	358	$133,077	85%	$113,116
Infrastructure Maint.	$72,483,639	Track Miles	666	$108,850.64	85%	$92,523

Based on 2009 Financial Reports of MBTA to Federal Transit Administration

The Study team used the information in Table B.2 to estimate O&M cost drivers for each commuter rail option. These cost drivers are increased train miles, increased rolling stock (locomotives and coaches), and increased track miles.

Table B.2: Cost Drivers used for Preliminary Estimates of Commuter Rail Operating Costs

Commuter Rail Service Options	Weekday Train Miles	Morning Peak Locomotives	Morning Peak Coaches	Track Miles
Base Service	1,452	4	24	53
Concord Regional	1,957	5	36	115
Concord Commuter	2,374	5	36	115
Manchester Regional	2,068	5	36	98
Manchester Commuter	2,091	5	36	98
Nashua Commuter	1,888	5	36	80
Nashua Minimum	1,496	5	36	72
Increments above Base Service				
Concord Regional	505	1	12	62
Concord Commuter	922	1	12	62
Manchester Regional	616	1	12	45
Manchester Commuter	639	1	12	45
Nashua Commuter	436	1	12	27
Nashua Minimum	44	1	12	19

An annualization factor of 300 weekday equivalents per year was used to convert weekday train miles into an estimate of annual train miles. The product of the cost drivers multiplied by the cost factors for each service option yielded the six sets of forecasts shown in Table B.3.

Table B.3: Preliminary Estimates of Commuter Rail Operating Costs (In Millions, 2009$)

Commuter Rail Service Options	Operations	Mechanical Maintenance	Infrastructure Maintenance	Total
Concord Regional	$3.16	$1.62	$6.23	**$11.10**
Concord Commuter	$5.60	$1.58	$6.04	**$13.30**
Manchester Regional	$3.76	$1.57	$4.37	**$9.70**
Manchester Commuter	$3.94	$1.58	$4.38	**$9.90**
Nashua Commuter	$2.58	$1.55	$2.58	**$6.80**
Nashua Minimum	$0.35	$2.25	$2.48	**$5.20**

Intercity Rail – Each intercity rail option was developed to the same level of detail as the commuter rail service options, including estimates of daily train miles, rolling stock requirements, track miles required, number and location of stations, and service schedules. The three preliminary options were reviewed with Amtrak staff assigned to advise the Study team and revised to reflect their feedback. The Study team also consulted with Amtrak for guidance on preparing preliminary estimates of operating costs for the Service Development Plan (SDP) (Appendix 9 to the AA Final Report). The Study team was referred to documentation from several recent SDPs:

- *Feasibility Report on Proposed Amtrak Service: Chicago-Rockford-Galena-Dubuque*; prepared by M.W. Franke, Sr. Director – Corridor Planning and R.P. Hoffman Principal Officer – Midwest Corridors, Amtrak, Chicago, Illinois; revised June 22, 2007
- *Feasibility Report on Proposed Amtrak Service: Quad Cities-Chicago*; prepared by M.W. Franke Assistant Vice President – State and Commuter Partnerships (Central), R. P. Hoffman Principal Officer – Midwest Corridors and B. E. Hillblom Senior Director – State Partnerships; Amtrak Chicago, Illinois; January 7, 2008
- *Feasibility Report of Proposed Amtrak Service: Chicago – Peoria*; prepared by Policy and Development Department (Central) Amtrak, Chicago, Illinois; September 26, 2011
- *New York-Vermont Bi-State Intercity Passenger Rail Study: Identification and Evaluation of Alternatives*; March 9, 2012

Review of these documents revealed that the preliminary (and final) operating cost estimates for SDPs are typically derived in two ways. A measure of annual train miles is often the only cost factor used to derive a very simple and transparent operating cost estimate while other studies rely on Amtrak staff to develop estimates. The Study team used the annual train mile approach as documentation concerning Amtrak's methodology is not publicly available. Amtrak reviewed these findings and agreed that the average costs per train mile published for the Amtrak *Downeaster* service would be used to estimate operating costs for Capitol Corridor intercity rail options. The use of the *Downeaster* service between Brunswick, Maine and Boston, Massachusetts is especially appropriate since this service also operates on tracks owned by MBTA and PAR and runs into Boston's North Station.

The most recent data on the *Downeaster* service indicated that it costs roughly $36 per train mile to operate. This metric is roughly equivalent to the costs applied for Midwestern and New York/Vermont

services reviewed in the studies recommended by Amtrak. Using the simple cost of $36 per train mile, the preliminary estimates of operating cost in Table B.4 were derived for the three intercity service options.

Table B.4: Derivation of Preliminary Estimates of Intercity Rail Operating Costs (2012$)

Intercity Service Option	Trips per Day	Train Miles per Day	Train Miles per Year	Annual Operating Cost (@ $36/train mile)
Intercity 8	8	590	214,040	$7,705,300
Intercity 12	12	880	321,050	$11,557,940
Intercity 18	18	1,320	481,580	$17,336,920

Commuter Bus – Weekday service schedules were developed for each of the three commuter bus options, including estimates of vehicle requirements and bus miles. Each schedule was reviewed with BX and revised to reflect their advice and input. Service statistics and cost summaries used to develop a preliminary cost model were also provided by Boston Express (BX) and included in Appendix B-1 to this memorandum.

Cost drivers for the preliminary cost model were the size of the vehicle fleet and revenue vehicle miles traveled. BX provided an annual average maintenance cost per vehicle of $27,032 and information on total operating costs, including vehicle maintenance. The residual operating costs that remained after vehicle maintenance had been accounted for were used to derive an average operations and management cost of $4.17 per bus mile. These variables were used to estimate the annual operating costs for the three service options as summarized in Table B.5.

Table B.5: Derivation of Preliminary Estimates of Commuter Bus Operating Costs (2012$)

Service Statistics and Costs	Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
Peak Vehicles	20	30	20	30
Total Fleet including Spares	22	38	22	38
Revenue Vehicle Miles Travelled (RVMT)	1,286,685	1,914,368	1,286,685	1,914,368
Fuel, Crew, and Supervision per RVMT	$4.17	$4.17	$4.17	$4.17
Maintenance Expense per Coach	$27,032	$27,032	$27,032	$27,032
Vehicle Maintenance Expense	$594,704	$1,027,216	$594,704	$1,027,216
Vehicle Operating Expense	$5,364,033	$7,980,768	$5,364,033	$7,980,768
Preliminary Estimate of Total Expense	**$5,958,737**	**$9,007,984**	**$5,958,737**	**$9,007,984**

Feeder Bus – A feeder bus service was proposed for the Nashua Minimum Commuter Rail option to provide supplemental midday connecting service between the MBTA station in Lowell, Massachusetts and the proposed South Nashua station. Another feeder bus was proposed for the Manchester Regional Commuter Rail option to provide supplemental midday connecting service between the proposed Nashua Crown Street station and the proposed station in downtown Manchester. Schedules for the two proposed services were included in the timetables prepared for the two commuter rail options so that values for the vehicles required, number of trips, vehicle miles, and vehicle hours could be developed. Information for three nearby transit agencies reported to the FTA in 2012 (see Appendix C-1 to this

memorandum) was used to estimate cost components for the proposed feeder bus service as shown in Table B.6. These transit agencies were the Lowell Regional Transit Authority (LRTA), Manchester Transit Authority (MTA), and the Nashua Transit System (NTS).

Table B.6: Derivation of Preliminary Estimates of Feeder Bus Operating Costs (2012$)

Service Statistics and Costs	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail
Vehicles Required	1	1
Bus Trips per Day	8	12
Daily Vehicle Miles	164	162
Daily Vehicle Hours	3.9	5.8
Annual Vehicle Miles	41,820	41,310
Annual Vehicle Hours	986	1,479
Mech. Cost per Vehicle Mile	$34,935	$34,509
Transport Cost per Vehicle Hour	$45,939	$68,908
Annual O&M Cost	**$80,874**	**$103,417**

Summary of Preliminary Estimates of O&M Costs – The preliminary estimates of O&M cost for each rail and bus service option are found in Table B.7.

Table B.7: Preliminary Estimates of Annual O&M Costs (In Millions, 2009$ for Commuter Rail Options, 2012$ for Intercity and Bus Options)

Service Option		Total
Commuter Rail Options		
	Concord Regional	$11.1
	Concord Commuter	$13.3

TOD	Transit-Oriented Development

1 Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs more "car-light" mobility options
- Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences

2 Task Objective

This report summarizes the detailed evaluation of the following 12 initial preliminary transit alternatives, plus the no build option:

- No Build (Base)
- Concord Regional Rail
- Concord Commuter Rail
- Manchester Regional Commuter Rail
- Manchester Commuter Rail
- Nashua Commuter Rail
- Nashua Minimum Commuter Rail
- Intercity 8
- Intercity 12

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

- Intercity 18
- Expanded Base (increased bus service)
- Bus on Shoulder (existing service levels)
- Expanded Bus on Shoulder (increased service)

3 Evaluation Criteria

The Study team initially used the following evaluation criteria, listed in the original scope, to evaluate those alternatives:

- **Environmental impacts**. Are there any environmental fatal flaws that would, by themselves, be cause for eliminating an alternative?
- **Land use and economic development**. Relative to the other alternatives, how likely is it that an alternative would help promote desirable development patterns, in particular denser, walkable, mixed-use neighborhoods near transit stations, i.e., Transit-Oriented Development (TOD)?
- **Transportation impacts**. Compared with the other options, what is the average weekday ridership in terms of total boardings?
- **Financial cost**. What is the total capital cost (construction, equipment, stations, track right-of-way and signal upgrades, highway improvements) of each alternative?

While much of the assessment and ranking was qualitative and based on the Study team members' extensive transit experience and knowledge of the Boston-Concord corridor, the team produced preliminary capital cost and ridership data to guide this early screening process. Numbers were later refined for Task 7 detailed analysis (Appendix 7 to the AA Final Report). Table 3.1 shows preliminary cost and ridership estimates used in this preliminary evaluation process.

Table 3.1: Preliminary Cost and Ridership Estimates

Alternative	Capital Cost (In Millions, 2014$)	Ridership (Total Weekday Boardings)
Existing (Base) NH Transit Riders	$0	2,400
No Build/Base	$0	---
Concord Regional Rail	$226	2,700
Concord Commuter Rail	$206	3,020
Manchester Regional Commuter Rail	$164	3,120
Manchester Commuter Rail	$164	3,060
Nashua Commuter Rail	$124	2,040
Nashua Minimum Commuter Rail	$124	1,480
Intercity 8	$162	1,460
Intercity 12	$174	1,720
Intercity 18	$174	2,040
Expanded Base	$6	346
Bus on Shoulder	$2	692
Expanded Bus on Shoulder	$9	1,038

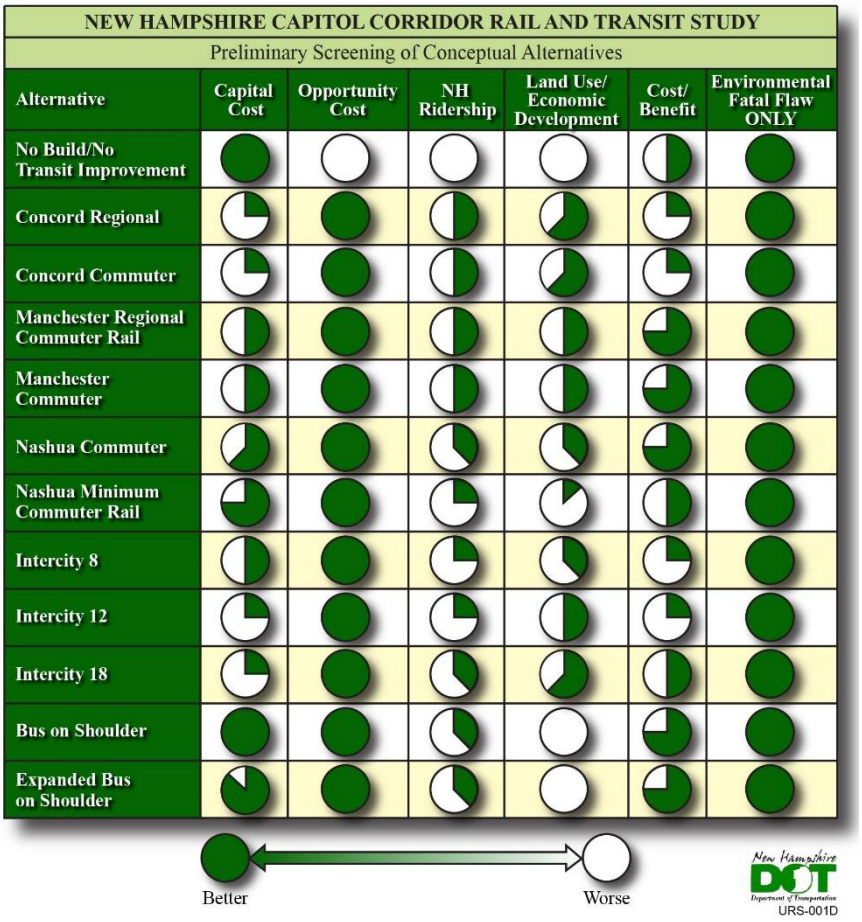
4 Alternative Evaluation

Based on the data above, professional judgment relating to environmental impacts, and land use and economic development potential, the Study team rated each alternative. In addition to those criteria, in consultation with the Federal Transit Administration's (FTA's) regional office staff in Cambridge, Massachusetts, the Study team added two additional evaluation criteria:

1. **Cost-benefit ratio:** how successfully does an alternative deliver greater benefits at a comparatively low cost?
2. **Opportunity cost:** weighed against the financial savings resulting from doing nothing (or doing relatively little), what are the resulting costs in terms of opportunities lost, for example, foregone development and additional transit options?

Figure 4.1 shows the ratings. Each alternative received a qualitative rating from best (full circle) to worst (empty circle), or, in most cases, somewhere in between. Ratings (and therefore rankings) are *relative to the other alternatives in the Capitol Corridor Study – rather than to any national standards or projects in other regions around the country.*

Figure 4.1: Alternative Ratings based on Preliminary Screening



5 Key Findings and Conclusions

5.1 Rail vs. Bus Tradeoffs: Cost and Development Impacts

Bus and rail alternatives can both perform well in terms of costs and benefits, but for very different reasons: bus options tend to rate low on cost (good) and benefit (not good) measures, while rail rates high on both.

In general, bus alternatives are far less expensive than rail projects. And for the Capitol Corridor, costs naturally rise as options move north from Lowell to Nashua, and then to Manchester and Concord.[2] However, in transit planning, benefits often rise with costs, and this is certainly true with the rail-bus tradeoffs in the Capitol Corridor. Thus, while rail costs are significantly higher than those for bus-based strategies, the benefits resulting from rail are also considerably greater, especially regarding beneficial land use and development impacts. As noted above, the type of development sought for this project is TOD, which is denser, mixed-use (commercial plus residential), walkable development near transit stations. Experience in the U.S. indicates that rail investments are more likely than bus investments to help spur that kind of desirable development. (That is not to say that bus facilities are not associated with development – Exit 5 on I-93 south of Manchester, for example – just not TOD, which is an objective of this Study.)

Naturally, as alternatives extend further to the north, total TOD potential increases with each city, with the greatest opportunities in Manchester, which already has major TOD elements, and Concord. Because of the station location at Crown Street, less opportunity exists in Nashua.

However, from a cost-benefit as opposed to benefit-only standpoint, alternatives providing service to Concord decline sharply north of Manchester, which effectively marks the peak of cost-benefit performance.

5.2 Opportunity Costs: The Cost of Doing Nothing

As noted above, after discussions with FTA, the Study team added an opportunity cost column to the evaluation matrix. Typically, in transit planning the focus is on the financial cost of implementing a project. However, for the Capitol Corridor Study, it is important to consider the costs of not making a transit investment. These include environmental costs and the costs to individuals and the broader population and economy from a lower quality-of-life that would result from not making a major transit investment.

Finally, while environmental impacts (positive and negative) are very important, for the purposes of screening alternatives in this early Study phase, the Study team considered only major negative impacts

[2] A potentially important caveat: the low cost for bus on shoulder alternatives assumes very limited highway improvements would be required in Massachusetts, where the feasibility of infrastructure requirements and strategy cost were being studied as of May 2014

that would be likely to disqualify alternatives. None were found. As the Study continued, Environmental Assessments (EAs) were completed (see Appendices 10a and 10b to the AA Final Report).

5.3 Intermediate Alternatives

The preliminary alternatives assessment helped guide selection of a set of alternatives to advance into more detailed analysis. Selection was also guided by input from two major public meetings in Manchester and Concord and by extensive discussions with public- and private-sector stakeholders (Task 1, Appendix 1 to the AA Final Report) in New Hampshire and Massachusetts.[3] In addition, the decision on final alternatives followed extensive consultation with the FTA and the Federal Railroad Administration (FRA).

The seven alternatives that advanced to further analysis (intermediate alternatives) included four bus-only and three rail-plus-bus options as follows and depicted in
Figure 5.1:

1. **No Build/Base**. Existing bus service from Concord and Manchester to Boston via I-93 and Route 3; no additional cost
2. **Bus on Shoulder**. Existing bus service using I-93 shoulders in Massachusetts
3. **Expanded Base**. Additional service on the existing system
4. **Expanded Bus on Shoulder**. Additional service, using the I-93 shoulders in Massachusetts
5. **Nashua Minimum Commuter Rail**. An extension of the MBTA Lowell line to North Station in Boston terminating in South Nashua; this is lowest-cost rail alternative of the initial 12 alternatives, retaining existing bus service on I-93 between Concord, Manchester, and South Station and Logan Airport in Boston and along Route 3
6. **Manchester Regional Commuter Rail**. An extension of the MBTA Lowell line terminating in downtown Manchester; when the decision on final options was made, this was judged to be the most cost-effective initial option; it would also retain existing bus service on I-93 and Route 3
7. **Intercity 8**. Intercity service from Concord to North Station overlaid on existing MBTA Lowell line service, operating similarly to the Amtrak Boston-Brunswick *Downeaster* service; this is the lowest cost of the original intercity alternatives and maintains all existing bus service on I-93 and Route 3

Each of the seven alternatives, except No Build, was defined in greater detail to help assure more accurate cost-benefit estimates. Detailed evaluation criteria were then developed in Task 6 (Appendix 6 to the AA Final Report) and were used to evaluate the alternatives in Task 7 (Appendix 7 to the AA Final Report), leading to a recommended strategy in Task 8 (Appendix 8 to the AA Final Report).

1 Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs more "car-light" mobility options
- Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

2 Task Objectives

The initial set of rail and bus alternatives were defined in Task 4 and evaluated in Task 5 (Appendices 4 and 5, respectively, to the AA Final Report), an exercise that resulted in selection of seven intermediate alternatives:

1. No Build/Base Bus (Base)
2. Expanded Base
3. Bus on Shoulder
4. Expanded Bus on Shoulder
5. Nashua Minimum Commuter Rail
6. Manchester Regional Commuter Rail
7. Intercity 8

This report identifies and defines eight evaluation criteria used to further assess those seven alternatives:

1. **Ridership**. What is the average weekday ridership for each alternative?
2. **Costs: Capital and Operations & Maintenance (O&M)**. What is the cost to build and operate each alternative?
3. **Land Use Impacts**. To what degree does an alternative result in relatively compact, environmentally sensitive development patterns?
4. **Economic Development Impacts.** How does the alternative contribute to the economy of the corridor and region?
5. **Equity and Environmental Justice.** What are the relative impacts on lower-income and minority communities?
6. **Environmental Impacts.** How does the alternative affect the natural, social, and economic environments?
7. **Financial Feasibility.** What is the likelihood of developing a financial plan that will fund the construction and operation of the alternative?
8. **Public Support.** How strong is the support for the alternative, to the point of moving it into implementation, including the acceptance of a feasible financial plan?

These eight criteria were then grouped into broader categories – e.g., “financial considerations” includes costs (capital and O&M) and feasibility of a financial plan and public support of that plan.

Detailed discussion of the travel demand forecasting (ridership) and equity technical methodologies used to produce data and other non-quantitative assessments of the relative impacts of the seven alternatives are provided in Appendices A and B, respectively, to this report. Detailed discussion of the capital and O&M costs used to produce data and other assessments of the relative impacts of the seven alternatives are included as appendices to the Task 7 Technical Report, Detailed Evaluation of Alternatives, provided as Appendix 7 to the AA Final Report.

Appendix A
Rail Ridership Forecast Methodology Memorandum

TECHNICAL MEMORANDUM

This document describes the Capitol Corridor rail ridership forecasting model development and presents forecasts for the Manchester Regional Commuter Rail and Nashua Minimum Commuter Rail alternatives.

Model Development

The forecast models use the existing Massachusetts Bay Transportation Authority (MBTA) commuter rail system to estimate parameters for forecasting commuter rail boardings on the proposed New Hampshire extensions of MBTA's system.

Multiple models were estimated with parameter inputs including rail operations data (service frequency, headway, and travel time), station characteristics (parking, highway access, transit service, distance between stations, and distance to Boston), socio-economic data (population, household income, vehicle ownership, employment), the Census Transportation Planning Package (CTPP) journey-to-work (JTW) data, and available MBTA system boarding data. A recommended model was selected from the estimated models based on the following criteria:

- **Model Statistical Performance:** The model must be statistically valid.
- **Expected Relationships between Model Parameters:** The model must make sense. If an additional train is provided in the peak period, daily boards should increase more than if the additional train was provided in the off-peak period.
- **Expert Opinion:** A set of statistically valid models was developed and reviewed by the Study team. These models were presented to the Federal Transit Administration (FTA), which approved the preferred model.

The recommended model inputs and the reasons why each were used are discussed below.

- **Frequency of peak and off-peak trains** accounts for the impacts of differing levels of service on ridership. Trains in the peak direction during peak travel times are expected to attract more riders than trains during off-peak times and direction. A train is considered to be a peak train if it arrives in Boston between 6:00am and 9:30am or if it departs Boston between 4:00pm and 7:00pm. Inclusion of the peak and off-peak frequency in the model enables the model to be sensitive to the differing frequency of service in the commuter rail alternatives.
- **JTW data** provide information on the size of the work market to Boston around each station. JTW trips to downtown Boston are associated with the closest commuter rail station where

they would board if they were to use the commuter rail to go to work. Inclusion of JTW data provides a measure of the number of workers who could possibly use the proposed rail service.

- **Employment around the station** informs the potential for a station to attract trips other than those destined for Boston, such as reverse/intermediate commute trips and non-work related trips. The total employment within a half-mile of each station is calculated. A half-mile buffer is used to allow for walk access to the employment location.
- **Park-and-ride (P&R) station designation** accounts for the impacts of parking availability. A park-and-ride station is characterized as having a large parking lot that is not located in a densely developed area. MBTA P&R stations have a greater number of boardings than non-P&R stations. The inclusion of a P&R designation allows the model to be sensitive to differences in the proposed stations, with the South Nashua and Bedford/Manchester-Boston Regional Airport (Manchester Airport) stations designated as P&R lots in the alternatives.

Model Forecasts

Opening day forecasts on the Manchester Regional and Nashua Minimum Commuter Rail alternatives are presented in Tables 1.1 and 1.2. Model results are presented with a forecast value and an upper- and lower-bound that are the 95 percent confidence interval around the forecast value. It is important to note that, as with all forecasts, the predictions are not a single value but rather a range of possible values.

Table 1.1: Manchester Regional Daily Boarding Estimates

Station	Forecast	Lower Bound	Upper Bound
Manchester, NH	270	180	390
Bedford/Manchester Airport	280	230	350
Nashua	420	330	540
South Nashua	590	440	800
TOTAL	**1,560**	**1,180**	**2,090**

Table 1.2: Nashua Minimum Daily Boarding Estimates

Feeder Bus Weight	Forecast	Lower Bound	Upper Bound
South Nashua	590	450	770

The estimated model predicts daily boards for each proposed station (see Table 1.3). These boards represent one-half of a daily round trip. To convert these boarding data to daily ridership, a factor of two is applied to account for the second-half of the round trip.

Table 1.3: Daily Ridership Estimates

Alternative	Ridership	Lower Bound	Upper Bound
Manchester Regional	3,130	2,350	4,170
Nashua Minimum	1,170	890	1,540

Appendix B
Corridor and Regional Equity Analysis Methodology Memorandum

TECHNICAL MEMORANDUM

Transit investment within the Capitol Corridor will confer benefits on corridor and regional residents, and may also generate adverse impacts that will be mitigated through project design, environmental clearance, and engineering phases. Building on the Civil Rights Act of 1964 and Executive Order 12898, the United States Department of Transportation (USDOT) has directed federal agencies, including the Federal Transit Administration and Federal Railroad Administration, to "ensure that all federally funded transportation-related programs, policies, or activities having the potential to adversely affect human health or the environment involve a planning and programming process that explicitly considers the effects on minority populations and low-income populations."[2] This detailed analysis – which is commonly referred to as environmental justice analysis – will be performed through the project environmental clearance process.

The equity analysis will include a high-level assessment of each alternative's potential for disproportionally adverse impacts on households below the poverty line, minority individuals, and households living in affordable housing units, as well as mobility and access benefits conferred to these households and individuals by each alternative. The purpose of this memorandum is to describe the methodology used to perform the equity analysis.

Income and Poverty

Data regarding average median household income and the percentage of households living below the federal poverty line will come from the U.S. Census Five-Year American Community Survey (2007-2011 and 2008-2012) for Census tracts within a half-mile of any alternative under consideration.

This data will be compared at the station area, corridor, state, and national levels to analyze which alternatives under consideration are serving areas with comparatively lower-income households and comparatively higher concentrations of households living below the federal poverty line.

[2] http://www.fta.dot.gov/12347_2238.html

Minority Population

Data regarding share of non-white (minority) population will be pulled from the U.S. Census Five-Year American Community Survey (2008-2012) for Census tracts within a half-mile of any alternative under consideration.

This data will be compared at the station area, corridor, state, and national levels to analyze which alternatives under consideration are serving areas with comparatively higher shares of a non-white population.

Affordable Housing

Data regarding the presence of affordable housing within the station areas of the alternatives under consideration were pulled from online research and conversations with municipal officials. While this list likely will not be inclusive of all affordable housing units within each station area, it will provide an order-of-magnitude estimate of affordable housing counts to support a comparison between the alternatives.

Data generated through the equity analysis will be used to support evaluation of transit investment alternatives, and may the form the basis of more detailed equity and environmental justice analyses that will be performed as the project progresses through subsequent development phases.

Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs more "car-light" mobility options
- Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences

Task Objectives

In Task 7, the intermediate set of alternatives selected in Task 5 (Appendix 5 to the AA Final Report) – one intercity rail, two commuter rail, and three express bus – are evaluated using criteria developed in Task 6 (Appendix 6 to the AA Final Report).

- Section 1 of this report, "Definition of Intermediate Alternatives," describes the three bus, two commuter rail, and one intercity rail investment options that advanced through preliminary screening leading towards the selection of a recommended strategy.
- Section 2 of this report, "Application of Selection Criteria," discusses how the Study team evaluated each alternative according to five criteria: economic impacts, land use and economic development, equity impacts, financial considerations (including costs), and mobility impacts (including ridership forecasts).

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

Overall analysis results were used, along with other important factors such as public and key stakeholder input, to select a transit investment strategy – the subject of Task 8 (Appendix 8 to the AA Final Report).

1 Definition of Intermediate Alternatives

Task 5 detailed analyses led to selection of seven (from 12) transit alternatives for further study. Table 1.1 summarizes these seven intermediate alternatives.

Table 1.1: Summary of Intermediate Alternatives

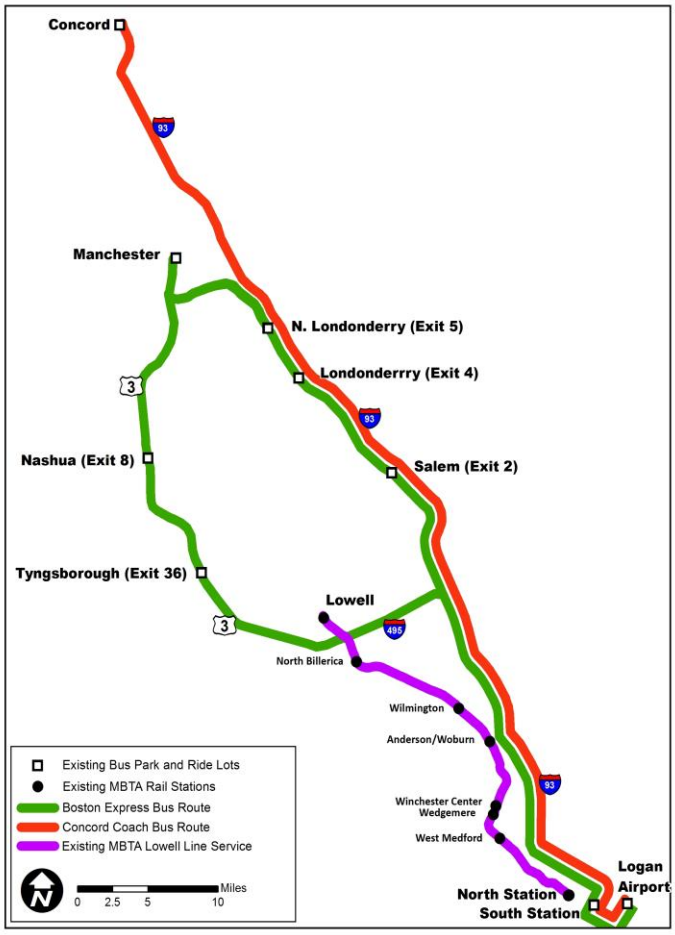
Base	▪ No investment; existing bus and rail services are continued, but not expanded
Expanded Base	▪ New Hampshire's Boston Express (BX) bus service is increased from current 80 buses per day to 120 buses per day ▪ All peak buses run direct and non-stop between each NH park-and-ride lot and Boston South Station with service every 30 minutes ▪ Each park-and-ride lot sees hourly off-peak service making intermediate stops at each NH park-and-ride lot ▪ No changes to existing passenger rail services
Bus on Shoulder	▪ BX bus service of 80 daily trips is permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes ▪ Savings of eight to 12 minutes predicted during the morning peak period ▪ No significant travel time savings predicted during the afternoon peak period
Expanded Bus on Shoulder	▪ 120 daily trips permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes ▪ Savings of eight to 12 minutes predicted during the morning peak period ▪ No significant travel time savings predicted during the afternoon peak period
Manchester Regional Commuter Rail	▪ Extends Massachusetts Bay Transportation Authority (MBTA) commuter rail service north from Lowell, MA to Manchester, NH with intermediate stops at South Nashua, Nashua Crown St., and Bedford/Manchester-Boston Regional Airport (Manchester Airport or MHT) ▪ BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained ▪ BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained
Nashua Minimum Commuter Rail	▪ Extends MBTA commuter service north from Lowell, MA to South Nashua, NH ▪ BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained ▪ BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained
Intercity 8	▪ Four daily intercity passenger rail round trips between Concord, NH and Boston, MA making intermediate stops at Manchester, Bedford/Manchester Airport, Nashua Crown St., and Lowell and Woburn, MA ▪ Base BX service is retained

1.1 Expanded Base

- New Hampshire's BX bus service is increased from current 80 buses per day to 120 buses per day
- All peak buses run direct and non-stop between each New Hampshire park-and-ride lot and Boston South Station with service every 30 minutes
- Each park-and-ride lot sees hourly off-peak (but not direct) service
- No changes to existing passenger rail services

The Expanded Base option (Figure 1.1) increases transit service frequency and directness within the Study Corridor by providing peak-period, point-to-point, non-stop trips from each of the New Hampshire park-and-ride lots to points within downtown Boston (southbound trips only), South Station, and Logan Airport. The service would add approximately 40 trips to the schedule and would require approximately 16 additional vehicles. There are no transit priority measures proposed in this option that would result in increased service velocities or decreased travel times.

Figure 1.1: Existing Corridor Bus and Existing Rail Services



Peak-period, point-to-point service would be provided at 30-minute headways, except for the Manchester service, which operates at 60-minute headways throughout the day. Hourly off-peak service would provide non-point-to-point service between each park-and-ride lot within the I-93 or Route 3 corridors and Boston South Station and Logan Airport without circulating through downtown Boston. A timetable for the proposed service is included in Index A at the end of this Section 1.

Anticipated ridership response to this service initiative would include increased ridership at all BX park-and-ride lots and some possible reduction of ridership on MBTA commuter rail service from Lowell and, perhaps, North Billerica, Massachusetts.

1.2 Bus on Shoulder

- Existing BX bus service of 80 daily trips is permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes
- Savings of eight to 12 minutes predicted during the morning peak period
- Savings of up to five minutes predicted during the afternoon peak period

The Bus on Shoulder option provides faster peak-period service by permitting buses to operate within the I-93 shoulder south of I-495 to bypass peak congestion in Massachusetts. Typical southbound morning peak-period savings would be eight to 12 minutes depending upon arrival time. Typical northbound afternoon peak-period savings would be approximately five minutes. The option would not add any additional trips or operate in a point-to-point manner, but would provide faster, more reliable

peak travel times. The proposed schedules maintain the existing arrival and departure times at South Station and modify the departure and arrival times at New Hampshire park-and-ride lots based on the estimated travel time savings resulting from Bus on Shoulder operation. The service would not require any additional vehicles to operate the proposed schedule. The timetable (see Index A at the end of this Section 1) prepared for this analysis reflects time savings estimated using a variety of sources. Ridership response to the service initiative is anticipated to include increased ridership at all BX park-and-ride lots and some possible reduction of ridership on MBTA commuter rail service from Lowell and, perhaps, North Billerica.

1.3 Expanded Bus on Shoulder

- 120 daily trips permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes
- Savings of eight to 12 minutes predicted during the morning peak period
- Savings of up to five minutes predicted during the afternoon peak period

The Expanded Bus on Shoulder option merges the increased frequency and directness of the Expanded Base option with the peak-period congestion bypass feature of the Bus on Shoulder option. It would offer faster and more direct peak service with more frequent off-peak service to all New Hampshire park-and-ride lots. The timetable prepared for this analysis merges the Bus on Shoulder and Expanded Base service concepts and can be found in Index A at the end of this Section 1. Ridership response to this service initiative is anticipated to include increased ridership at all park-and-ride lots and some possible reduction of ridership on MBTA commuter rail service from Lowell and, perhaps, North Billerica.

1.4 Manchester Regional Commuter Rail

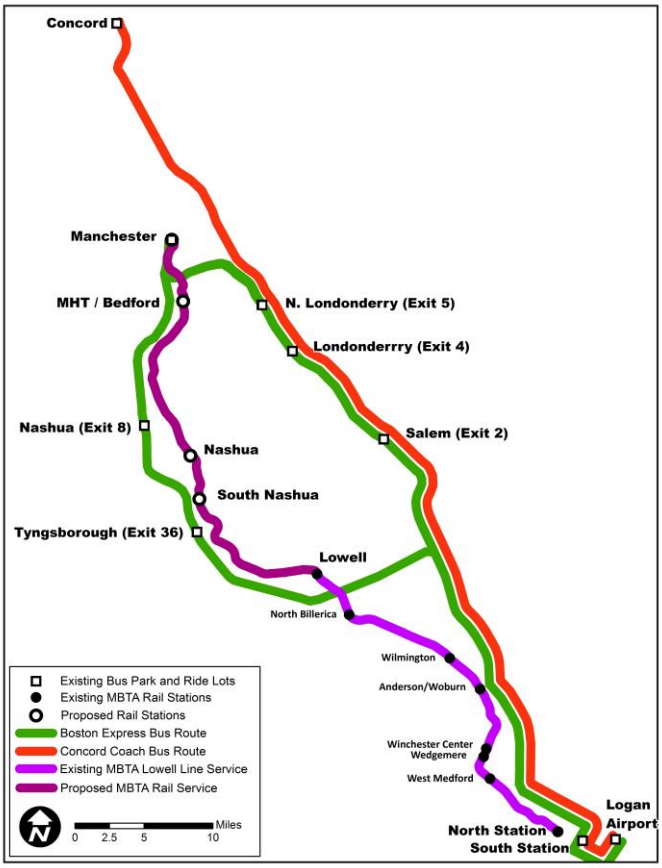
- Extends MBTA commuter rail service north from Lowell, Massachusetts to Manchester, New Hampshire with intermediate stops at South Nashua, Nashua Crown Street, and Bedford/Manchester Airport
- BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained
- BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained

The Manchester Regional Commuter Rail option would extend MBTA service 30 miles north from Lowell to downtown Manchester. The service initiative would provide all day commuter rail service between Boston and Nashua with a lower frequency regional service provided north to Manchester (see Figure 1.2). The service adds four new stations to the line with 16 weekday trains for Manchester and 34 weekday trains for Nashua. All existing MBTA deadhead trains on the Lowell Line would be eliminated.

Eight optional connecting bus trips could be added between South Nashua and Manchester to supplement the schedule of rail services with additional midday and evening mobility options. The existing BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem would be retained, as would BX Route 3 service to Nashua and Tyngsborough.

A layover facility for four train sets would be constructed in the vicinity of Manchester. Up to six coaches and one locomotive would be added to the MBTA's weekday equipment line-up. The number of weekday MBTA train miles operated on the line would increase 42 percent to 2,068. Six MBTA trains would be marginally adjusted with most changes required on light ridership reverse peak trains. The number of affected passengers would be 520 (3.9 percent) of 13,382 weekday riders. The total effect would be 10,202 passenger minutes of change (2.4 percent) out of 430,954 total daily passenger minutes of travel.

Figure 1.2: Proposed Manchester Regional Commuter Rail and Bus Service Configuration



Ridership response to this service initiative is anticipated to include new riders attracted to rail service provided to the proposed New Hampshire stations. It is assumed that some current MBTA rail passengers living in New Hampshire would shift to these new stations from the existing MBTA Lowell and North Billerica Stations. Ridership impacts on the BX I-93 main line services to Londonderry, North Londonderry, and Salem would be likely negligible.

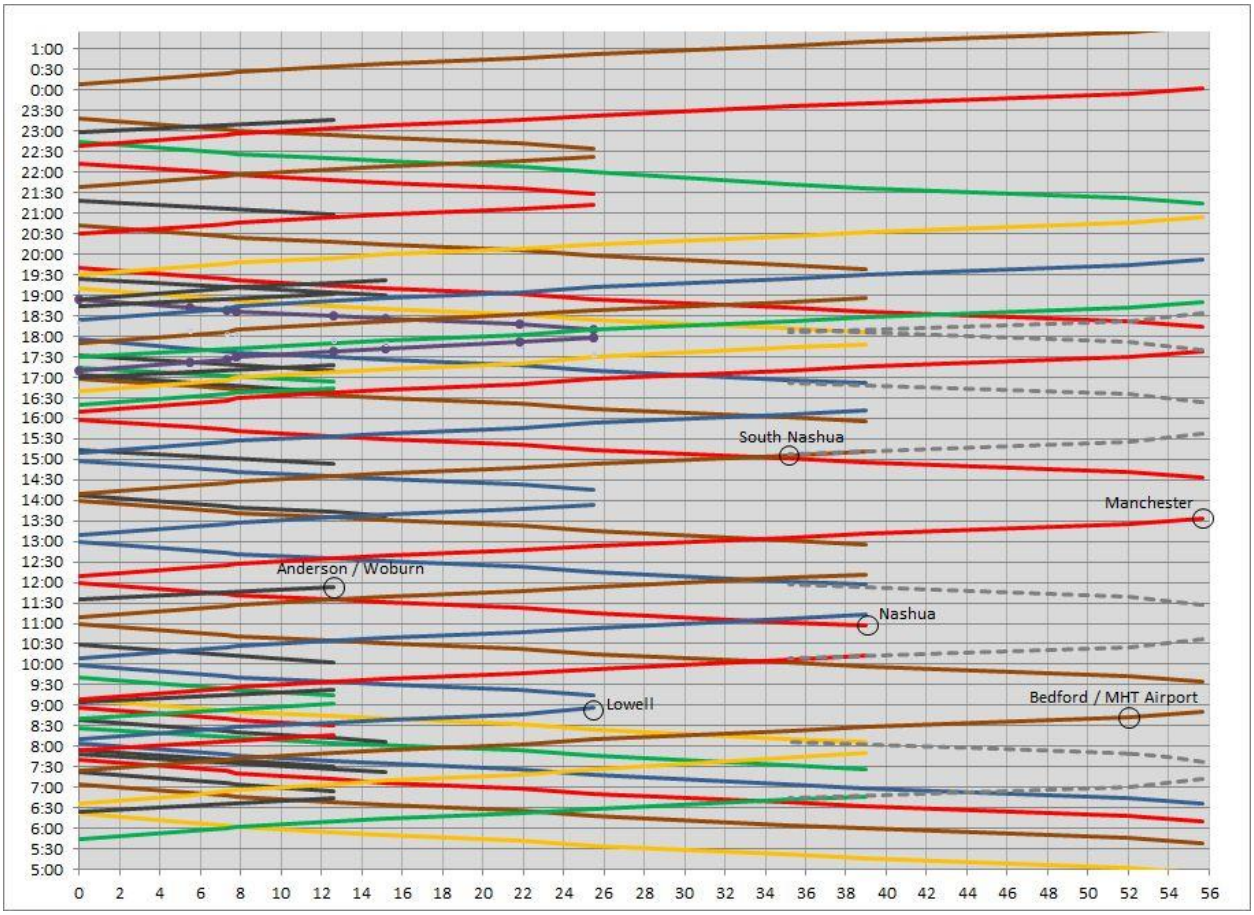
A timetable for the proposed service is included in Index B to this Section 1 and a stringline diagram is found in Figure 1.3. The stringline diagram graphically depicts the proposed schedule of passenger services. The vertical Y-axis represents time while the horizontal X-axis represents distance from Boston's North Station. The earliest portion of the day is at the bottom of the diagram. Boston is on the left of the chart while Manchester is on the right. Each train is graphed as a line indicating its movement through time and space. The colors represent unique train sets assigned to the service.

For example, the yellow line represents trainset "N." It departs Manchester at 4:54 as train 302 and returns north from North Station at 6:37 as train 305. It arrives in Nashua at 7:51 and returns south at 8:06 as train 312. Trainset "N" then operates along other lines during the midday until it departs North Station at 16:40 as train 329 and arrives in Nashua at 17:49. It returns south at 18:07 as train 338 arriving in North Station at 19:06. The final trip of the day departs North Station at 19:30 as train 339 and arrives in Manchester at 20:55. Trainset "N" then lays over in New Hampshire and completes the same schedule on the following day.

Optional midday and early evening feeder bus service would provide connecting service to fill out a complete schedule of services. Three midday and one early evening bus round trips linking South

Nashua, Bedford/Manchester Airport, and Manchester could supplement the peak-only rail service. The feeder bus service is represented in the stringline diagram by the dashed lines running between South Nashua and Manchester.

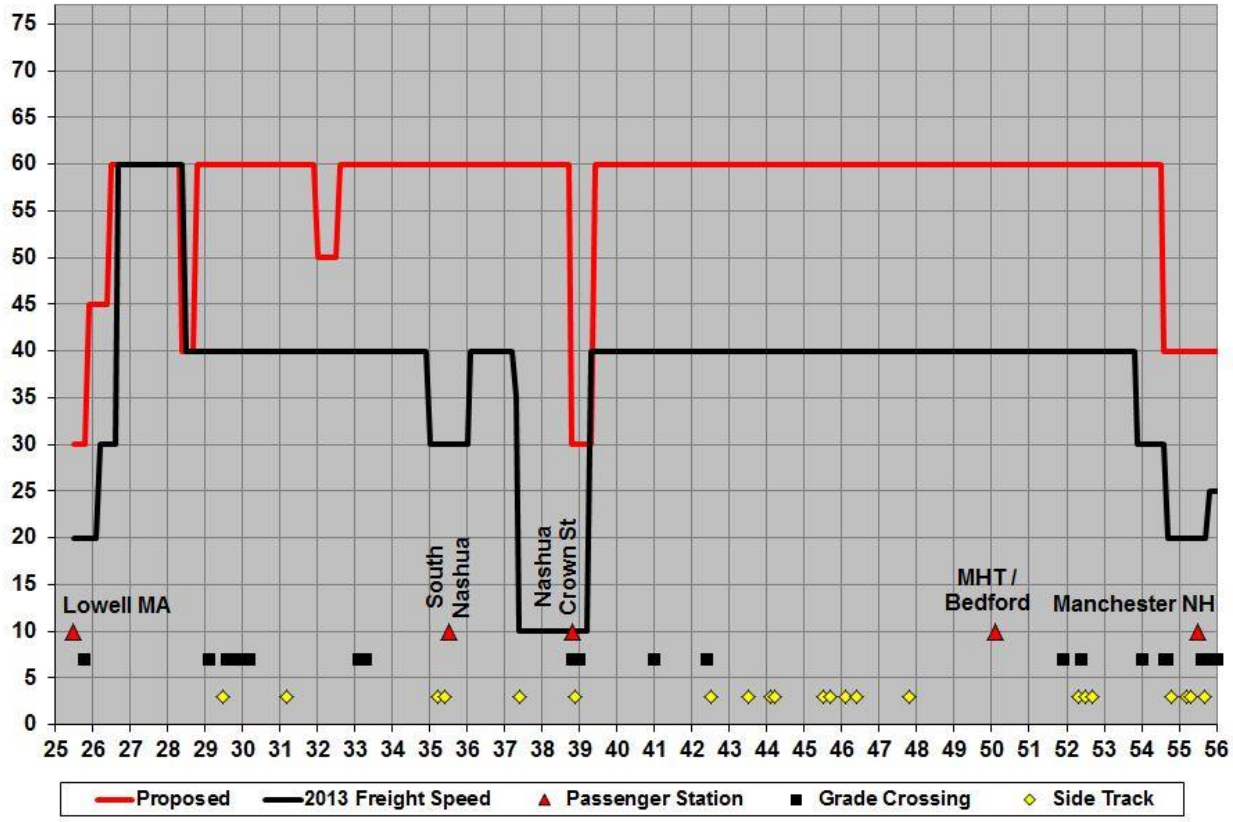
Figure 1.3: Time-Distance Stringline Diagram for Manchester Regional Commuter Rail Service



Infrastructure Requirements

No improvements would be required south of Lowell's Gallagher MBTA Terminal. North of Lowell the railroad would be upgraded to permit safe, reliable operation of 34 daily passenger trains making 16 round trips at speeds of up to 60 miles per hour (mph) (see Figure 1.4). Recommended upgrades to track, bridges, crossings, and signals are summarized below.

Figure 1.4: Current and Proposed Maximum Train Speeds for Manchester Regional Commuter Rail



Track – Study team engineers recommend that this option be supported by replacing nearly all the existing 70-plus-year-old main line rail between Lowell and Manchester with new continuous welded rail (CWR) of a similar weight. CWR is more expensive than jointed rail, but it is preferred because it is stronger, gives a smoother ride, allows for higher operating speeds, and has lower maintenance costs. Along segments where the rail is renewed with CWR, approximately one-quarter of the existing ties would be replaced to provide an additional margin of structural integrity in the track.

To facilitate meets between southbound and northbound passenger trains, a second track would be added between North Chelmsford (Mile Post [MP] 28.5) and the southern end of the Tyngsborough Curve (MP 32.0). Double track would also be extended through the Nashua and Manchester freight yards.

Industrial sidings would be created at three key areas of freight activity in Nashua and Merrimack to harmonize local freight deliveries with through passenger trains. At these locations the existing main line track would be retained as an industrial siding with an entirely new parallel main line track constructed in the same alignment for use by through trains. Adding a second track would be a straightforward undertaking, as the railway was once entirely double-tracked with the double-track bed still largely intact.

Bridges – The service expansion would use 16 existing bridges over watercourses or roadways (see Table 1.2). Most of the bridges are rated as having sufficient strength to accommodate the proposed additional traffic. One bridge in Tyngsborough (MP 32.5) is a candidate for complete replacement. The large steel (circa 1930) structure spanning the Merrimack River (MP 51.8) between Manchester and Bedford is subject to more detailed inspection. The other 14 bridges should receive a renewal of worn and weakened components when the rails crossing them are replaced.

Table 1.2: Manchester Regional Commuter Rail Bridge Inventory

MP	Length (Ft.)	PAR Rating (000's of lbs.)	Municipality	Overall Assessment
25.7	155	Not Available	Lowell	Fair
26.2	163	Not Available	Lowell	Fair
28.8	104	334	Chelmsford	Fair
28.8	44	350	Chelmsford	Good/Fair
29.1	13	350	Chelmsford	Fair
32.5	46	263	Tyngsborough	Fair/Poor
32.6	12	320	Tyngsborough	Good
37.9	17	350	Nashua	Good
39.2	113	350	Nashua	Fair
39.4	35	286	Nashua	Fair
41.8	48	350	Nashua	Good/Fair
44.8	16	289	Merrimack	Fair
44.9	108	350	Merrimack	Fair/Good
46.2	112	350	Merrimack	Good/Fair
47.8	10	350	Merrimack	Good/Fair
51.8	655	Not Rated	Manchester	Fair

Grade Crossings – With double tracking and increased frequency of faster trains, most of the roadway grade crossings between Granite Street in Manchester and Wotton Street in Chelmsford (listed in Table 1.3) would require upgrades to their Automatic Highway Warning Devices (AHWD). If requested by the communities, New Hampshire Department of Transportation (NHDOT) and the MBTA can work with the municipalities, PAR, and the Federal Railroad Administration (FRA) to establish "quiet zones" where desired.

Table 1.3: Manchester Regional Commuter Rail Grade Crossings

Municipality	MP	Street	Type	AHWD	Recommended Upgrades
Chelmsford	29.1	Wotton St.	Private	FGBX	Add provisions for second main line track
Chelmsford	29.6	Wellman Rd.	Private	CFGB	Add provisions for second main line track
Chelmsford	30.0	Cross St.	Private	None	Install FGBX for double-track main line
Tyngsborough	30.5	New England Marine	Private	None	Install FGBX for double-track main line
Tyngsborough	33.5	Helena Dr./River Rd.	Private	X	Install FGBX for single track main
Nashua	36.2	"Dustbowl"	Informal	None	Work with community to close or protect this informal crossing
Nashua	36.9	East Glenwood St.	Private	None	Install FGBX for single track main
Nashua	38.8	Crown St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Nashua	38.9	East Hollis St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Nashua	39.0	Bridge St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Nashua	40.8	Hills Ferry Rd.	Public	X	Install FGBX for single track main
Merrimack	42.4	Mast Rd.	Private	X	Install FGBX for single track main
Merrimack	43.7	Busch	Private	None	Work with Anheuser Busch to upgrade AHWD
Merrimack	44.1	Star Dr.	Private	None	Work with National Grid to upgrade AHWD
Merrimack	45.7	New England Pole	Private	X	Install FGBX for double-track main line
Manchester	52.1	Pine Island Rd.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	52.6	Winston Rd.	Public	FGBX	Renew crossing surface as new rail and ties are installed; provide for a three track crossing if this becomes the commuter railroad's overnight layover facility
Manchester	54.0	West Mitchell St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	54.6	Sundial Ave. (Dunbar St.)	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	54.7	Bryon St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	55.6	Depot St.	Public	FGBX	CLOSE
The column marked "AHWD" reports the types of "Automatic Highway Warning Devices" installed at each crossing. F=Flashers, G=Gates, B=Bell, X=Cross buck Sign, C=Cantilever over roadway with flashing lights, None=No AHWD					

Stations – Five new passenger stations would be constructed for the Manchester Regional Commuter Rail option (see Table 1.4). They would be a mix of high-level platforms and low-level platforms with MBTA "mini-high" platforms for handicapped accessibility. High-level platforms would be preferred at all locations. A low-level with mini-high platform approach would be employed where no path was available for PAR freight trains to avoid using the platform track to ensure a clear route for wide freight loads. A mini-high platform is a short, elevated platform that allows for wheelchair accessibility for one or two cars. Mini-high platforms are usually located at the end of the station away from Boston, allowing them to be served by the car nearest the locomotive.

Table 1.4: Manchester Regional Commuter Rail Passenger Station Development Plan

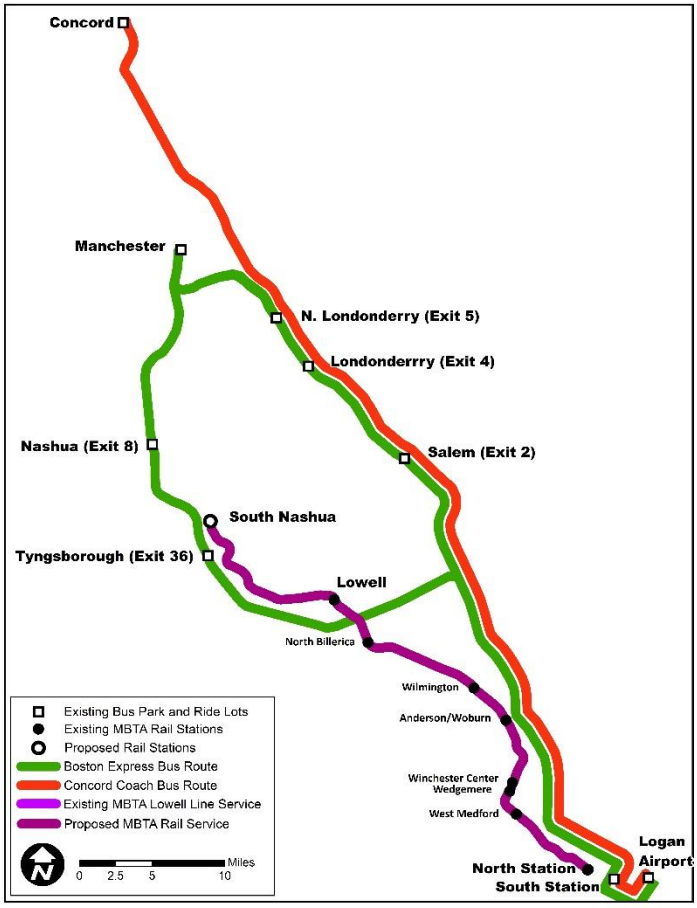
Station	MP	Type	Comments
Manchester	55.5	High-Level	Single high-level platform to the east of the eastern main line track
Bedford/MHT	50.1	Low-Level	Single low-level platform with mini-high to the west of the single main line track
Nashua	38.8	High-Level	Single island high-level platform between two main line tracks; oversize freight would run around platform using yard tracks
South Nashua	35.5	Low-Level	Single low-level platform with mini-high to the west of the single main line track

Other – Upgrades to the train control and signal systems would also be required as well as a number of new switches and interlockings. These details are described in detail in Appendix D, Capital Cost Methodology Report, to this report.

1.5 Nashua Minimum Commuter Rail

- Extends MBTA commuter service north from Lowell, Massachusetts to South Nashua, New Hampshire
- BX Route 3 service to Nashua and Tyngsborough is retained
- BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained

Figure 1.5: Proposed Nashua Minimum Commuter Rail and Bus Service Configuration



The Nashua Minimum Commuter Rail service option provides a minimal peak-period-only commuter rail service to and from South Nashua with no rail service further north to Manchester or Concord (Figure 1.5). It is specifically designed to minimize the MBTA operating cost of extending service to Nashua. It could be developed and operated as an interim service coordinated with bus service while markets and finances for further New Hampshire service were given time to develop.

MBTA service would be extended 13.5 miles north from Lowell to the South Nashua Station. The service adds one new station to the line with 20 weekday trains for South Nashua. A layover facility for four train sets would be constructed in the

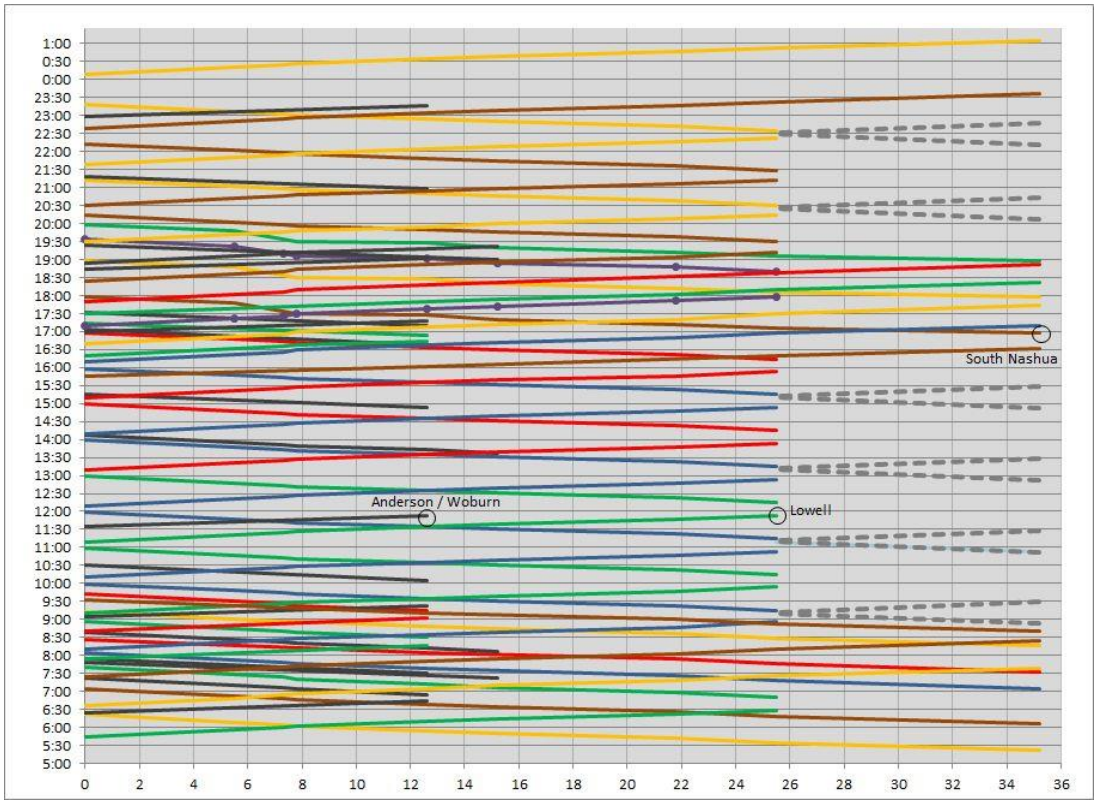
vicinity of South Nashua. No additional coaches or locomotives would need to be added to the MBTA's weekday line-up of equipment.

The number of weekday MBTA train miles operated on the line would increase only three percent to 1,496. Schedules for several MBTA trains would be marginally adjusted with most changes required on light ridership reverse peak trains. The number of affected passengers would be 876 (6.5 percent) of 13,382 weekday riders. The total effect would be 9,846 passenger minutes of change (2.3 percent) out of 430,954 total daily passenger minutes of travel.

A timetable for the proposed service is included in Index B to this Section 1 and a time-distance stringline diagram that graphically depicts the proposed schedule of passenger services is found in Figure 1.6.

Optional midday and early evening feeder bus service would provide connecting service to fill out a complete schedule of services. Three midday and two early evening bus round trips linking South Nashua with the Lowell MBTA train station could supplement the peak-only rail service. The feeder bus service is represented in the stringline diagram by the dashed lines running between Lowell and South Nashua. BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem would be retained, as would Route 3 service to Nashua and Tyngsborough.

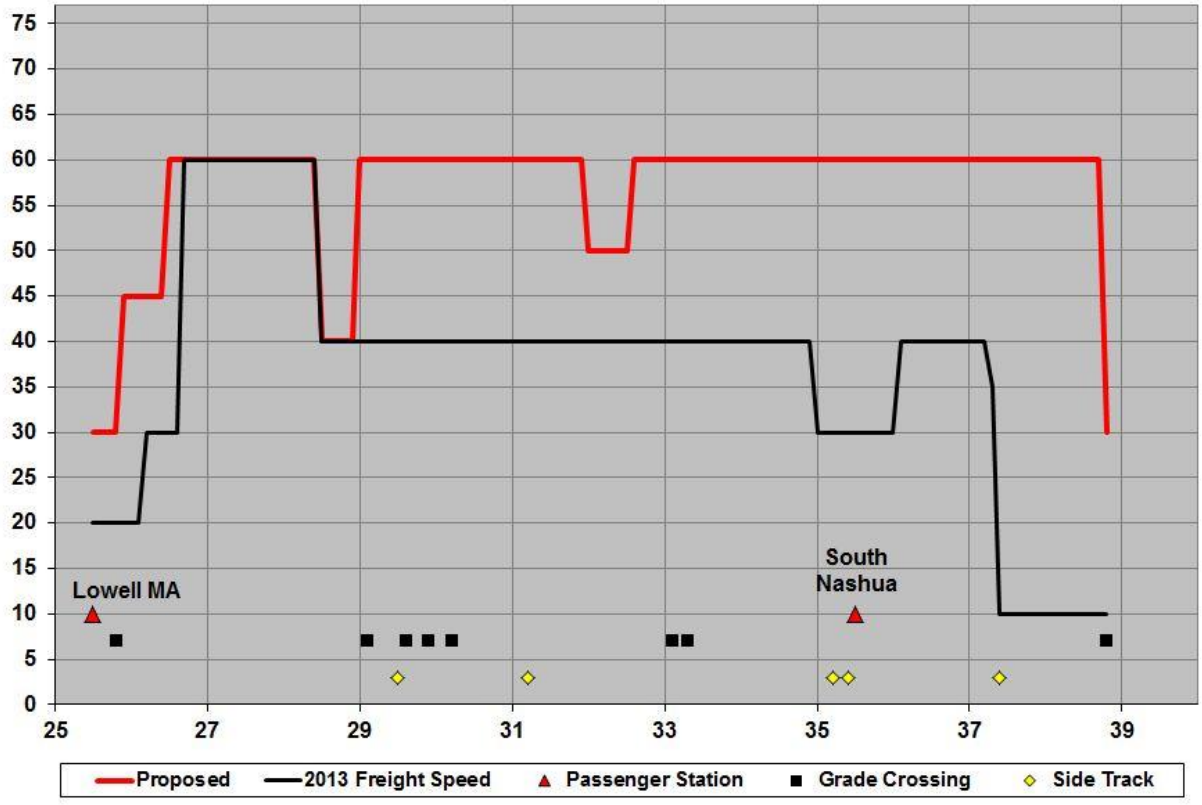
Figure 1.6: Time-Distance Stringline Diagram for Nashua Minimum Commuter Rail



Infrastructure Requirements

The Nashua Minimum Commuter Rail was specifically crafted to facilitate subsequent upgrades to the service, including a potential future extension to Manchester and more off-peak service to Nashua. Consequently, the infrastructure requirements for Nashua Minimum Commuter Rail are a subset of the proposed Manchester Regional Commuter Rail service needs. Like Manchester Regional, no improvements south of Lowell's Gallagher Terminal would be required. North of Lowell the railroad would be upgraded to permit safe, reliable operation of 20 weekday passenger trains at speeds of up to 60 mph (see Figure 1.7). Recommended upgrades to track, bridges, crossings, and signals are summarized below.

Figure 1.7: Proposed Maximum Allowable Passenger Speeds for Nashua Minimum Commuter Rail



Track – As proposed for the Manchester Regional Commuter Rail option, Study team engineers recommend that this option also be supported by replacing nearly all the existing 70-plus-year-old main line rail between Lowell and Nashua with new CWR of a similar weight. To facilitate meets between southbound and northbound passenger trains, a second track would be added between North Chelmsford (MP 28.5) and the southern end of the Tyngsborough Curve (MP 32.0). Unlike the Manchester Regional Commuter Rail option, no industrial sidings would be required because the service would not extend across the segments with the most intense freight activity.

Bridges – The service expansion would use eight existing bridges over watercourses or roadways (see Table 1.5). Most of the bridges are rated as having sufficient strength to accommodate the proposed additional traffic. One bridge in Tyngsborough (MP 32.5) is a candidate for complete replacement. The other seven bridges should receive a renewal of worn and weakened components when the rails crossing them are replaced.

Table 1.5: Nashua Minimum Commuter Rail Bridge Inventory

MP	Length (Ft.)	PAR Rating (000's of lbs.)	Municipality	Overall Assessment
25.7	155	Not Available	Lowell	Fair
26.2	163	Not Available	Lowell	Fair
28.8	104	334	Chelmsford	Fair
28.8	44	350	Chelmsford	Good/Fair
29.1	13	350	Chelmsford	Fair
32.5	46	263	Tyngsborough	Fair/Poor
32.6	12	320	Tyngsborough	Good
37.8	17	350	Nashua	Good

Crossings – With double tracking and increased frequency of faster trains, most of the roadway grade crossings between "Dustbowl" in Nashua and Wotton Street in Chelmsford listed in Table 1.6 would require upgrades in their AHWD. If requested by the communities, NHDOT and the MBTA can work with the municipalities, PAR, and the FRA to establish "quiet zones" where desired.

Table 1.6: Nashua Minimum Commuter Rail Grade Crossings

Municipality	MP	Street	Type	AHWD	Recommended Upgrades
Chelmsford	29.1	Wotton St.	Private	FGBX	Add provisions for second main line track
Chelmsford	29.6	Wellman Rd.	Private	CFGB	Add provisions for second main line track
Chelmsford	30.0	Cross St.	Private	None	Install FGBX for double-track main line
Tyngsborough	30.5	New England Marine	Private	None	Install FGBX for double-track main line
Tyngsborough	33.5	Helena Dr./River Rd.	Private	X	Install FGBX for single track main
Nashua	36.2	"Dustbowl"	Informal	None	Work with community to close or protect this informal crossing
Nashua	36.9	East Glenwood St.	Private	None	Install FGBX for single track main
The column marked "AHWD" reports the types of "Automatic Highway Warning Devices" installed at each crossing. F=Flashers, G=Gates, B=Bell, X=Cross buck Sign, C=Cantilever over roadway with flashing lights, None=No AHWD					

Stations – One new passenger station with a low-level platform would be constructed for the Nashua Minimum Commuter Rail option (see Table 1.7). An MBTA mini-high platform would be located at the north end of the station for handicapped accessibility.

Table 1.7: Nashua Minimum Commuter Rail Passenger Station Development Plan

Station	MP	Type	Comments
South Nashua	35.5	Low-Level	Single low-level platform with mini-high platform to the west of the single main line track

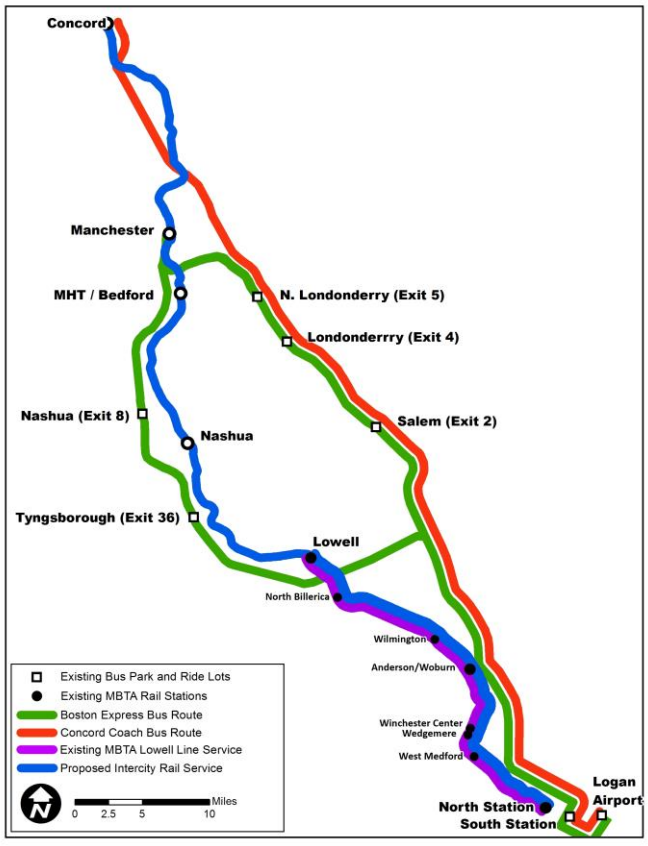
Other – Upgrades to the train control and signal systems would also be required as well as some new switches and interlockings. These details are covered in the Appendix D, Capital Cost Methodology Report, to this report.

1.6 Intercity 8

- Four daily intercity passenger rail round trips between Concord, New Hampshire and Boston, Massachusetts making intermediate stops at Manchester, Bedford/Manchester Airport, Nashua Crown Street, and Lowell and Woburn, Massachusetts
- BX Route 3 service to Nashua and Tyngsborough and BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained

The eight-train-per-day Intercity 8 rail option would provide four daily round trips over the 73-mile route stopping at five intermediate stations (see Figure 1.8). Intercity rail service would operate much like Amtrak's *Downeaster* service between Boston and Brunswick, Maine. The Intercity 8 option could be operated by Amtrak or the MBTA or contracted to a third-party service provider.

Figure 1.8: Proposed Intercity 8 Rail Service and Bus Service Configuration



The end-to-end trip time would be approximately 96 minutes and the service would operate 586 daily train miles. A timetable for the proposed service is shown in Table 1.8 and a full New Hampshire Main Line (NHML) schedule showing how the intercity trains would fit in with the existing Lowell line commuter rail service is found in Index C to this Section 1. A time-distance diagram showing the proposed service is found in Figure 1.9. Presuming an average cost of $36 per train mile, the Intercity 8 option would cost approximately $7.7 million per year to operate.

The service would provide connections in Concord to private bus services for North Country destinations. No changes are proposed to express bus service for commuting to Boston

via I-93 or Route 3. Local bus service to the intercity rail stations could be offered, but would not be integral to the service design. A BX/Concord Coach/intercity rail fare integration scheme similar to that used by the *Downeaster* at Portland, Maine could be employed at the Concord and Manchester stations that would be shared by both intercity rail and coach bus services.

Anticipated ridership responses to the service initiative would include new riders attracted to the intercity rail service. It is anticipated that few current MBTA passengers living in New Hampshire would shift from using MBTA Lowell and North Billerica Stations to the new intercity rail service. Some BX and Concord Coach customers may shift to intercity rail service from Nashua, Manchester, and Concord. The overall increase in the quality and frequency of transit options to Manchester and Concord may stimulate bus ridership, as has been observed at the shared terminal in Portland, Maine.

Table 1.8: Intercity 8 Timetable

380	382	384	386		Station	MP		381	383	385	387

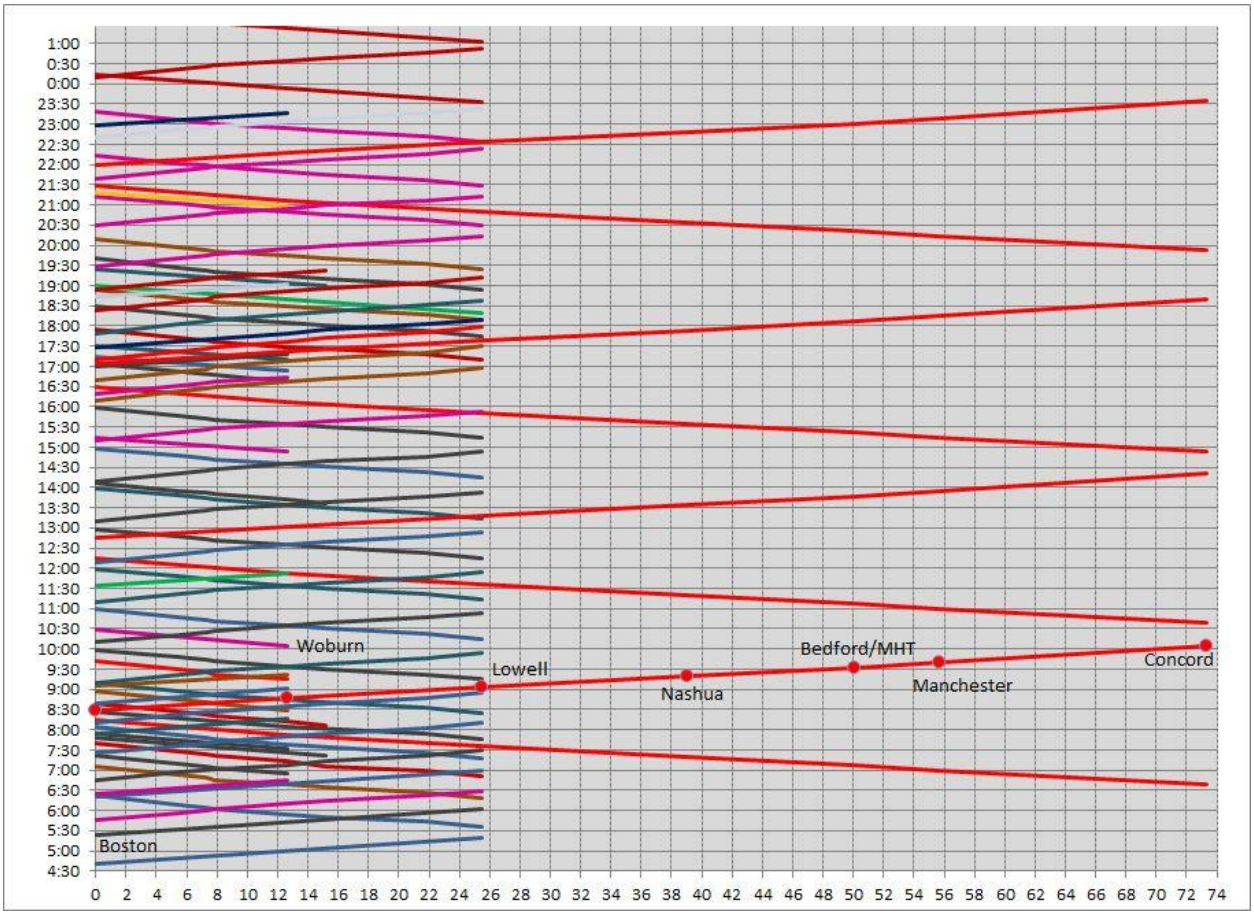
Figure 1.9: Time-Distance Stringline Diagram for Intercity 8 Rail Service

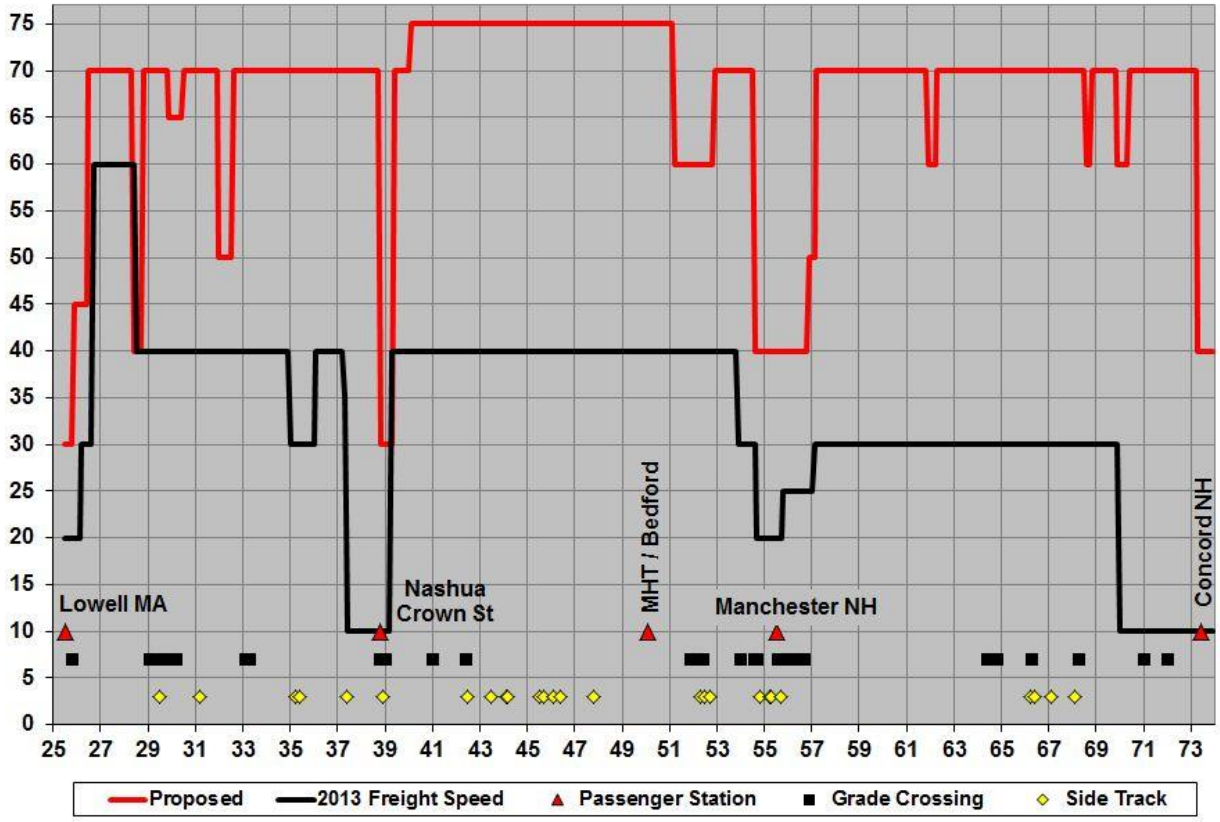


Infrastructure Requirements

No improvements would be required south of MBTA's Lowell Gallagher Terminal. North of Lowell the railroad would be upgraded to permit safe, reliable operation of eight daily passenger trains at speeds of up to 75 mph. Intercity 8 would require more extensive infrastructure upgrades than the commuter rail options as it is approximately 18 miles longer than the Manchester Regional Commuter Rail service. The service would also operate at higher maximum speeds: up to 75 mph between Manchester Airport and Nashua and 70 mph at many other locations (see Figure 1.10). Recommended upgrades to track, bridges, crossings, and signals are summarized below.

Track – Study team engineers recommend that this option be supported by replacing all of the existing 70-plus-year-old main line rail between Lowell and Concord with new CWR of a similar weight. Along segments where the rail is renewed with CWR approximately one-third of the existing ties would be replaced. This would provide an additional margin of structural integrity in the track over the one-quarter of existing ties that would be replaced for 60 mph maximum speeds.

Figure 1.10: Proposed Maximum Passenger Speeds for Intercity 8 Rail Service



Unlike the Manchester Regional and Nashua Minimum Commuter Rail options, no double track would be required between North Chelmsford (MP 28.5) and the southern end of the Tyngsborough Curve (MP 32.0). Industrial sidings would be created at three key areas of freight activity in Nashua and Merrimack to eliminate conflicts between local freight deliveries and through passenger trains. At these locations the existing main line track would be retained as an industrial siding with an entirely new parallel main line track constructed in the same alignment for use by through trains. Adding a second track would be straightforward as the railway was once entirely double tracked with the double-track bed still largely intact.

Bridges – The service expansion would use 25 existing bridges over watercourses or roadways (see Table 1.9). Most of the bridges are rated as having sufficient strength to accommodate the proposed additional traffic. One bridge in Tyngsborough (MP 32.5) is a candidate for complete replacement. The large steel (circa 1930) structure spanning the Merrimack River (MP 51.8) between Manchester and Bedford is subject to more detailed inspection. In Hooksett, the 488-foot steel bridge also spanning the Merrimack is similarly subject to more detailed inspection. The other 22 bridges should receive a renewal of worn and weakened components when the rails crossing them are replaced.

Table 1.9: Intercity 8 Bridge Inventory

MP	Length (Ft.)	PAR Rating* (000's of lbs.)	Town	Overall Assessment
25.7	155	Not Available	Lowell	Fair
26.2	163	Not Available	Lowell	Fair
28.8	104	334	Chelmsford	Fair

67.6	15	286	Bow	Good/Fair
70.8	17	286	Bow	Good/Fair
71.1	11	350	Bow	Good/Fair
71.5	16	Not Rated	Concord	Good
71.5	10	Not Rated	Concord	Fair
73.3	Short	Not Rated	Concord	Fair

Crossings – With double tracking and increased frequency of faster trains, most of the 35 roadway grade crossings between Concord and downtown Lowell listed in Table 1.10 would need upgrades to their AHWD. The density of crossings just north of the proposed Granite Street Station in Manchester is very high. If requested by the communities, NHDOT and the MBTA can work with the municipalities, PAR, and FRA to establish "quiet zones" where desired.

Table 1.10: Intercity 8 Grade Crossings

Municipality	MP	Street	Type	AHWD	Recommended Upgrades
Chelmsford	29.1	Wotton St.	Private	FGBX	Add provisions for second main line track
Chelmsford	29.6	Wellman Rd.	Private	CFGB	Add provisions for second main line track
Chelmsford	30.0	Cross St.	Private	None	Install FGBX for double-track main line
Tyngsborough	30.5	New England Marine	Private	None	Install FGBX for double-track main line
Tyngsborough	33.5	Helena Dr./River Rd.	Private	X	Install FGBX for single track main
Nashua	36.2	"Dustbowl"	Informal	None	Work with community to close or protect this informal crossing
Nashua	36.9	East Glenwood St.	Private	None	Install FGBX for single track main
Nashua	38.8	Crown St.	Public	FGBX	Renew crossing surface as new rail and ties are installed.
Nashua	38.9	East Hollis St.	Public	FGBX	Renew crossing surface as new rail and ties are installed.
Nashua	39.0	Bridge St.	Public	FGBX	Renew crossing surface as new rail and ties are installed.
Nashua	40.8	Hills Ferry Rd.	Public	X	Install FGBX for single track main
Merrimack	42.4	Mast Rd.	Private	X	Install FGBX for single track main
Merrimack	43.7	Busch	Private	None	Work with Anheuser Busch to upgrade AHWD
Merrimack	44.1	Star Dr.	Private	None	Work with National Grid to upgrade AHWD
Merrimack	45.7	New England Pole	Private	X	Install FGBX for double-track main line
Manchester	52.1	Pine Island Rd.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	52.6	Winston Rd.	Public	FGBX	Renew crossing surface as new rail and ties are installed; provide for a three track crossing if this becomes the commuter railroad's overnight layover facility
Manchester	54.0	West Mitchell St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	54.6	Sundial Ave. (Dunbar St.)	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	54.7	Bryon St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	55.6	Depot St.	Public	FGBX	CLOSE
Manchester	55.7	Granite St.	Public	CFGBX	Renew crossing surface as new rail and ties are installed
Manchester	55.9	Pleasant St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	56.0	Ped Xing #1	Public	FBX	Renew crossing surface as new rail and ties are installed
Manchester	56.2	Spring St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	56.3	Kidder St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	56.5	Ped Xing #2	Public	FBX	Renew crossing surface as new rail and ties are installed
Manchester	56.6	Commercial St.	Public	FGBX	Renew crossing surface as new rail and ties are installed
Manchester	58.7	Eve St. (Chauncey Ave.)	Private	X	Install FGBX for single track main
Hooksett	64.3	Old Londonderry Turnpike	Public	FGBX	Renew crossing surface as new rail and ties are installed
Hooksett	64.8	Edgewater Dr.	Public	FBX	Renew crossing surface as new rail and ties are installed
Bow	66.3	Johnson Rd.	Public	FBX	Renew crossing surface as new rail and ties are installed
Bow	68.3	Robinson Ferry	Private	X	Install FGBX for single track main
Bow	69.8	Gavins Falls Rd.	Private	None	Install FGBX for single track main
Bow	71.0	Hall St.	Public	FGBX	Renew crossing surface as new rail and ties are installed

The column marked "AHWD" reports the types of "Automatic Highway Warning Devices" installed at each crossing.
F=Flashers, G=Gates, B=Bell, X=Cross buck Sign, C=Cantilever over roadway with flashing lights, None=No AHWD

Stations – Four new passenger stations would be constructed (see Table 1.11). They would be a mix of high-level and low-level platforms with mini-high platforms for handicapped accessibility. The platforms at Nashua and Manchester would be less complex than for the commuter rail options because no intercity trains would turn from northbound to southbound at these stations.

Table 1.11: Intercity 8 Passenger Station Development Plan

Station	MP	Comments
Concord	73.3	Single high-level platform on the stub end terminal track east of the main line
Manchester	55.5	Single low-level platform with mini-high to the east of the single main line track
Bedford/MHT	50.1	Single low-level platform with mini-high to the west of the single main line track
Nashua	38.8	Single low-level platform with mini-high to the west of the single main line track

Other – Upgrades to the train control and signal systems would also be required as well as some new switches and interlockings. These details are covered in Appendix D, Capital Cost Methodology Report, to this report.

2 Application of Selection Criteria

The application of five selection criterion is discussed in the following sections of this document:

- Economic impacts
- Land use and economic development
- Equity impacts
- Financial considerations, including costs
- Mobility impacts, including ridership forecasts

In addition, technical memoranda that detail the analysis supporting criteria application are appended to this report:

- Economic development (Appendix A)
- Sustainable land use (Appendix B)
- Corridor and regional equity analysis (Appendix C)
- Capital costs (Appendix D)
- Operations and maintenance (O&M) costs (Appendix E)
- Ridership forecasting (Appendix F)

2.1 Economic Impacts

An economic development assessment aimed at estimating the potential benefits associated with the set of final build alternatives in the corridor was conducted to examine two types of economic benefit:

1. The amount of new development that might occur locally around new station areas
2. The impact of this new development, plus the investment in new or upgraded transit infrastructure measured in terms of employment and economic output in the Capitol Corridor region

This assessment estimates benefits associated with the three rail alternatives, all of which provide new permanent infrastructure such as stations. In contrast, none of the bus alternatives involve new stations, and are, therefore, not expected to generate the development-based economic benefits.

Numerous studies done by transportation research organizations have identified a net positive benefit of fixed-guideway transit investment to the regional economy. This economic benefit is a result of travel time savings and congestion reduction, expanded access to jobs and workforce, and new development attracted to station areas. Studies have also found a positive impact of transit on property values in station areas. There are very few studies of the economic impacts of bus enhancement projects, and, of those, none suggest that the kinds of enhancements contemplated in the Capitol Corridor would help catalyze new, more intense development.

The Study team assembled data on land use and zoning to evaluate the potential impact of the Capitol Corridor project alternatives on development and redevelopment. This potential was measured in terms

of commercial square footage (office and retail) and housing units for the different alternatives. The Study team estimated the following illustrative impacts, as summarized in Table 2.1.

Table 2.1: Total Station Area Development Potential by Alternative

Alternative	Commercial (Sq. Ft.)	Residential (Units)	Jobs
Manchester Regional Commuter Rail	1,898,000	3,600	5,600
Nashua Minimum Commuter Rail	930,000	1,100	2,500
Intercity 8	819,000	1,600	2,500
Intercity Bus	0	0	0
No Build (Base)	0	0	0

Note: residential units and jobs rounded to the nearest hundred

- **Manchester Regional Commuter Rail** – This alternative, serving four stations in Nashua and Manchester at a moderate-to-high frequency, would have the greatest benefit. It has the potential to generate more than 3,600 new residential units and nearly two million square feet of commercial space supporting 5,600+ new jobs by the year 2030.
- **Nashua Minimum Commuter Rail** – This alternative, serving one station in Nashua at moderate-to-high frequency, could potentially generate about 1,100 new residential units and 930,000 square feet of commercial space supporting 2,500 new jobs by the year 2030.
- **Intercity 8** – With four trains per day serving Nashua, Manchester, and Concord, this alternative could potentially generate about 1,600 new residential units and 819,000 square feet of commercial space supporting 2,500 new jobs by the year 2030. While the same number of stations would be served for Manchester Regional Commuter Rail, impacts per station would be somewhat lower due to the lower service frequency.
- **Bus Alternatives** – Capital improvements associated with the bus alternatives range from additional buses to operate increased levels of service, to roadway improvements that would help buses bypass congestion by operating on the shoulder along I-93 south of I-495. These alternatives differ from the three rail alternatives above in that they will not include new stations around which Transit-Oriented Development (TOD) might occur. For this reason, and notwithstanding other benefits associated with bus improvements such as reductions in travel times, the kinds of economic development benefits documented in this assessment are not expected to occur for the bus alternatives. This is supported by the literature and was the consensus opinion of the stakeholders interviewed.

The Study team used this data to measure development potential at the individual stations. The analysis shows that the commuter rail alternatives consistently perform better from both a jobs and development perspective. The Concord location could potentially generate the highest square feet of commercial space in either scenario; the downtown Manchester location could potentially generate the greatest number of residential units; and the Nashua Spit Brook Road location has the potential to support the greatest number of jobs. See the summary in Tables 2.2 and 2.3.

Table 2.2: Commuter Rail Development Potential in Each Station Area

Alternative	Commercial (Sq. Ft.)	Residential (Units)	Jobs
Manchester – Bridge St.	587,000	1,410	2,040
Manchester – Granite St.*	567,000	1,360	1,970
Bedford – MHT*	245,000	0	720
Nashua – Crown St.*	155,000	1,110	410
Nashua – Spit Brook Rd.*	930,000	1,120	2,480
Nashua – Pheasant Lane Mall	116,000	0	280

**Included in summary totals for Manchester Regional Commuter Rail*

Table 2.3: Intercity Rail Development Potential in Each Station Area

Concord – Stickney Ave.*	335,000	400	890
Manchester – Bridge St.	294,000	710	1,020
Manchester – Granite St.*	284,000	680	980
Bedford – MHT*	123,000	0	360
Nashua – Crown St.*	77,000	560	210
Nashua – Spit Brook Rd.	465,000	560	1,240
Nashua – Pheasant Lane Mall	58,000	0	140

**Included in summary totals for Intercity 8*

The economic modeling tool IMPLAN was used to estimate the broader economic benefits to the southern New Hampshire region of each Capitol Corridor project rail alternative and its associated station area development. For this assessment, the following regional economic benefits were evaluated:

- Short-term benefits as a result of spending on construction of rail improvements in New Hampshire
- Long-term benefits as a result of the attraction of more residents and jobs to southern New Hampshire; these include benefits related to the construction of new real estate in station areas, as well as ongoing benefits from new worker earnings reinvested in the local economy

Benefits of time savings to travelers cannot be directly monetized in this type of economic analysis. However, they are capitalized into land values and, therefore, are indirectly considered through the real estate effects. Benefits of the bus alternatives were not estimated, as these alternatives would involve minimal capital investment and the literature, stakeholder interviews, and the Study team's professional experience suggest that associated development impacts would also be minimal.

The economic modeling provides the following illustrative regional impacts, as summarized in Tables 2.4 and 2.5:

- **Manchester Regional Commuter Rail** – This alternative has moderate construction impacts and the highest development-related impacts. It has the potential to generate 230 new jobs over the construction period (2019-2022), about 3,390 jobs related to new real estate development between 2021 and 2030,[2] and about 1,730 new jobs annually in 2030 and beyond (with benefits beginning to accrue after 2021) due to reinvested worker earnings. Real estate development would add $1.2 billion to the state's output between 2021 and 2030, with reinvested earnings adding $220 million per year beyond 2030.
- **Nashua Minimum Commuter Rail** – This alternative generates the lowest construction and development impacts since only one new station is located in New Hampshire. It has the potential to generate 80 new jobs over the construction period (2019-2022), more than 850 jobs related to new real estate development between 2021 and 2030, and nearly 380 new jobs annually in 2030 and beyond due to reinvested worker earnings. Real estate development would add $260 million to the state's output between 2021 and 2030, with reinvested earnings adding $50 million per year beyond 2030.
- **Intercity 8** – This alternative generates the greatest construction impacts, but lesser development-related impacts compared to the Manchester Regional Commuter Rail alternative because of its lower-service frequency. It has the potential to generate 350 new jobs over the construction period (2019-2022), 2,460 jobs related to new real estate development between 2021 and 2030, and 1,140 new jobs annually in 2030 and beyond (with benefits beginning to accrue after 2021) due to reinvested worker earnings. Real estate development would add $750 million to the state's output between 2021 and 2030, with reinvested earnings adding $140 million per year beyond 2030.

Table 2.4: Impacts on Employment (Jobs) by Alternative

Alternative	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	230	3,390	1,730
Nashua Minimum Commuter Rail	80	850	380
Intercity 8	350	2,460	1,140
Bus on Shoulder	0	0	0
No Build	0	0	0

These impacts are in addition to the new jobs located in station areas as shown in Tables 2.2 and 2.3

[2] A new "job" over a multi-year period is really a "job-year," i.e., 3,400 jobs over a 10-year period is equivalent to 340 jobs that each continue for the entire 10-year period

Table 2.5: Impacts on Output (Gross Regional Product) by Alternative (In Millions, 2014$)

Alternative	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	$70	$1,200	$220
Nashua Minimum Commuter Rail	$20	$260	$50
Intercity 8	$100	$750	$140
Bus on Shoulder	0	0	0
No Build	0	0	0

2.2 Land Use and Economic Development

Each of the alternatives was also evaluated for its ability to support local land use goals and to catalyze and support economic development activity within station areas.

Generally, the cities of Concord, Manchester, and Nashua have transit-supportive plans and policies. Specifically, three of the potential station locations (downtown Concord, Manchester [both Bridge and Granite Street sites], and Nashua Crown Street) have transit-supportive existing zoning and land use. These policies support further transit growth and TOD around the potential stations. The other three potential stations (Bedford/Manchester Airport/South Suburban Manchester, Nashua South at Spit Brook, and Nashua South at Pheasant Lane Mall) have less transit-supportive existing zoning and land use around each of the potential stations. These areas would more likely be developed as a park-and-ride station and less focused on integrating residential and mixed-use types of developments.

When evaluated at the individual station level, the number of jobs within a half-mile of each potential station is categorized as “low” per the Federal Transit Administration (FTA) breakpoints. However, the FTA evaluates this criterion by looking at the total number of jobs within a half-mile of all the stations on the line (not by individual station); this includes North Station in Boston and all stations on the existing MBTA Lowell Line commuter rail in Massachusetts. When including this data in the project calculation, the total number of jobs served by the Lowell Line and the proposed Capitol Corridor extension results in a “medium” FTA rating for employment served.

Some of the potential station locations are better suited for TOD and supporting growth in transit than others. The four sites in the urban centers (Concord, Manchester [Bridge or Granite Streets], and Nashua Crown Street) are all primed for future transit growth and TOD. Potential stations on the municipalities’ outskirts (Bedford/Manchester Airport/South Suburban Manchester, Nashua South at Spit Brook, and Nashua South at Pheasant Lane Mall) all lack strong existing zoning and plans/policies that support their future growth as transit hubs. However, they would be good locations for park-and-ride stations, which are intended as their primary function.

2.2.1 *Sustainable Land Use*

A sustainable transportation system is one that meets and balances the existing environmental, social, and economic needs of a community without compromising resources for future generations. Each alternative was evaluated for its ability to meet land use goals in these three categories.

- Environmental goals:
  - Catalyze more compact, infill transit-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power) to support new development and supporting maintenance of existing open/rural space
  - Reduce reliance on cars for trips/errands
- Social goals:
  - Expand mobility and transportation choice for all age cohorts
  - Support low-income households through increased access to jobs
- Economic goals: Alternatives that create more opportunities for people to move efficiently from place-to-place and open up more connections to transportation serve to increase access and mobility. Access and mobility also affect the economies of the places served by transportation at local and regional levels:
  - Attract employers to New Hampshire
  - Attract and retain regional employers to New Hampshire and Boston
  - Provide improved residency location choice in New Hampshire for commuters to Boston or regional jobs

Table 2.6 presents the composite assessments for each of the three categories of sustainable land use goals by alternative.

Table 2.6: Summary of Goals by Alternative

	Alternative						
	Base	**Expanded Base**	**Bus on Shoulder**	**Expanded Bus on Shoulder**	**Manchester Regional Commuter Rail**	**Nashua Minimum Commuter Rail**	**Intercity 8**

Social Goals	no change	low	low	low	low/medium	low	low/ medium
Economic Goals	no change	medium	low	medium	medium	low	medium
Summary Assessment	**no change**	**low**	**low**	**low/medium**	**medium**	**low**	**medium**

2.3 Equity Impacts

Equitable access to transit investments – and the mobility benefits that these investments confer on riders – is an important consideration when assessing the alternatives. Public transit investment supports broad improvements in mobility, but is a particularly critical tool in increasing the mobility of transit-reliant or -dependent populations, including households below the poverty line, minorities, and households in affordable housing units.

U.S. Census data was used to calculate statistics related to income, race, and housing for households and individuals in Census Tracts within a half-mile of the Capitol Corridor alternatives (PAR right-of-way between the state lines of New Hampshire and Massachusetts and the potential rail station location in Concord, New Hampshire; BX bus route between the state lines of New Hampshire and Massachusetts and the existing Manchester, New Hampshire BX station; the Concord Coach bus route between the state lines of New Hampshire and Massachusetts; and the existing Concord, New Hampshire Concord Coach station). This data was also collected for New Hampshire and Massachusetts, and the U.S. comparison between the alternatives within the larger geographic context will support the analysis of which alternatives minimize potential adverse impacts on concentrations of households below the poverty line, minority populations, and households in affordable housing units, while supporting equitable transit access by these populations.

The three populations considered as part of this equity analysis – population below the poverty line, minority populations, and households living in affordable housing units – tend to be concentrated in the central areas of Concord, Manchester, and Nashua. When compared to the base and bus alternatives, the rail alternatives offer comparatively higher levels of service and transit access to these populations with minimal adverse impacts anticipated. The equity of and access to the rail alternatives improve as transit service extends north from Nashua (to Manchester and/or Concord) because those alternatives (Manchester Regional Commuter Rail and Intercity 8) reach more individuals and households living below the poverty line, minority households, and households living in affordable housing units. The base and all bus alternatives would not adversely impact these populations either, but also would not offer expanded access to these populations through new station locations.

Table 2.7 provides a summary of the equity metrics for each existing bus station and proposed rail station.

Table 2.7: Summary of Alternatives

Station Area (Half-Mile Buffer)	Proposed Rail Station	Existing Bus Station	Equity Metrics				Stations Served by Alternative(s)			
			Average Median Income	Population Below Poverty	Minority Population	Affordable Housing Units	Base and All Bus Alternatives	Intercity 8	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail
Concord, NH	X	X	$39,000	18.0%	9.7%	398	X	X		
Manchester, NH	X	X	$30,300	29.5%	26.1%	675	X	X	X	
Bedford/MHT	X		$65,500	4.5%	5.2%	0		X	X	
N. Londonderry, NH		X	$82,900	1.7%	4.7%	minimal	X			
Londonderry, NH		X	$84,700	3.9%	5.2%	minimal	X

2.4 Capital and O&M Costs

2.4.1 Capital Costs

Summary of Estimated Rail Costs

Estimated capital costs for each final rail service option are summarized below and in Table 2.8.

Table 2.8: Summary of Project Capital Costs (In Millions, 2014$)

	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Main Line Tracks	$29.7	$15.3	$42.1
Track Switches	$6.4	$2.8	$7.8
Interlockings	$10.6	$5.1	$12.0
Block Signals	$1.0	$0.4	$1.2
Grade Crossing Signals	$5.0	$1.4	$8.3
Grade Crossing Track Renewals	$3.3	$0.8	$5.6
Bridges	$10.7	$2.1	$15.4
Stations	$20.8	$6.3	$18.7
Layovers	$12.4	$13.4	$4.8
Right-of-Way Improvements	$6.2	$2.9	$8.8
Positive Train Control	$6.5	$2.9	$9.5
Railroad Appliances	$0.5	$0.1	$1.0
Direct Construction Expense Subtotal	**$113.3**	**$53.7**	**$135.2**
Multipliers for Allowances	$20.4	$9.7	$24.3
Railroad Services	$4.5	$2.1	$5.7
Land for Stations	$1.2	$0.3	$0.9
Land for Layovers	$0.6	$2.1	$1.4
Assemblage Allowance (220%)	$4.0	$5.3	$5.2
Subtotal Land	**$5.9**	**$7.8**	**$7.5**
Contingency	$50.0	$25.6	$60.5
Grand Total (infrastructure)	**$194.5**	**$98.9**	**$233.2**
Coaches	$27.8	$15.2	$12.7
Locomotives	$5.3	$5.3	$10.6
Grand Total (rolling stock)	**$33.2**	**$20.5**	**$23.3**
Trackage Rights	**$18.0**	**$0.9**	**$0.0**
Total Project Value	**$245.6**	**$120.3**	**$256.5**

- **Manchester Regional Commuter Rail** is projected to cost $143 million for infrastructure and land plus $50 million contingency allowance. This option cost also includes $33 million in rolling stock and $18 million in trackage rights that would be contributed by the Commonwealth of Massachusetts.
- **Nashua Minimum Commuter Rail** is projected to cost $73 million for infrastructure and land plus $26 million contingency allowance. This option cost also includes $20 million in rolling stock that would be contributed by the Commonwealth of Massachusetts. The value of the Massachusetts trackage rights for this option is $0.95 million as it would use roughly one mile of PAR right-of-way in New Hampshire to access a station and/or a layover facility at the Spit Brook Road site.
- **Intercity 8** is projected to cost $172 million for infrastructure and land plus a $60 million contingency allowance. This option cost also includes $23 million in rolling stock that would be the responsibility of NHDOT. This option would be operated by Amtrak (although no decision on an operator has been made); therefore, the value of Massachusetts acquired trackage rights would be zero since Amtrak has statutory authority to operate without acquiring trackage rights from PAR.

2.4.2 Summary of Estimated Bus Costs

Final estimates of capital costs for the bus options revolved around the same two factors applied to derive preliminary estimates: additional buses required to operate more frequent service and roadway upgrades required to allow for Bus on Shoulder operations providing faster peak service for some options.

As noted for the preliminary options, some bus service improvement options entailed increasing the frequency of bus service. These services would require additional rolling stock to operate. The Study team estimated the required number of additional buses by consulting with NHDOT and BX to determine the size and utilization of the current BX fleet. Study team analysis indicated that amending the current schedule of peak service to operate direct, non-stop, half-hourly peak service from all six park-and-ride lots currently served by BX would require an addition of 16 buses to BX's current fleet of 22 vehicles as shown in Table 2.9.

Table 2.9: BX Vehicle Requirements by Service Option

	Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
Vehicles to Operate Minimum Service (VOMS)	16	30	16	30
Fleet	22	38	22	38
Spares	6	8	6	8
% Spare	27%	21%	27%	21%

A preliminary estimate of $400,000 was included for new vehicles, but NHDOT informed the Study team that new vehicles would be expected to cost $600,000 each. Study team work on existing highway conditions found sufficient shoulder width for the 22 affected route miles between I-495 and Somerville, Massachusetts along I-93 to allow Bus on Shoulder operations without substantial investment in new right-of-way. A preliminary estimate of $100,000 per route mile[3] had been used based on early experience in Minnesota. For the final estimate, a more recent figure of $250,000 per route mile[4] was employed. Consistent with FTA guidance, a 35 percent contingency was applied to projected infrastructure costs (see Table 2.10).

Table 2.10: Final Capital Cost Estimates for Bus Options (In Millions, 2014$)

	Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
Vehicles Cost *	$0.0	$9.6	$0.0	$9.6
Infrastructure Cost **	$0.0	$0.0	$7.4	$7.4
Total Capital Cost	**$0.0**	**$9.6**	**$7.4**	**$17.0**

** New coaches at $600,000 each*
*** Infrastructure cost of $250,000 per route mile plus a 35% contingency allowance*

2.4.3 Final Estimates of Capital Costs

In summary, the final estimates of capital cost for each of the final rail and bus service options are found in Table 2.11.

Table 2.11: Final Estimates of Capital Cost (In Millions, 2014$)

Service Option	Infrastructure, Land and Contingency	Rolling Stock	Massachusetts Department of Transportation (MassDOT) Trackage Rights	Total
Commuter Rail Options				
Manchester Regional	$194.5	$33.2	$18.0	$245.6
Nashua Minimum	$98.9	$20.5	$0.0	$120.3
Intercity Rail Option				
Intercity 8	$233.2	$23.3	$0.0	$256.5
Bus Service Options				
Base	$0.0	$0.0	$0.0	$0.0
Expanded Base	$0.0	$9.6	$0.0	$9.6
Bus on Shoulder	$7.4	$0.0	$0.0	$7.4
Expanded Bus on Shoulder	$7.4	$9.6	$0.0	$17.0

[3] *TCRP Synthesis 64 Bus Use of Shoulders,* Peter C. Martin, Wilbur Smith Associates, San Francisco, CA, 2006, pg 20
[4] *TCRP Report 151 A Guide for Implementing Bus On Shoulder Systems*, Peter Martin and Herbert S. Levinson, Texas Transportation Institute, 2012, pg 2-5

2.4.4 O&M Costs

Refined O&M cost estimates were prepared for more detailed final analysis of the two commuter rail, one intercity rail, and three bus options that advanced through preliminary screening: Manchester Regional Commuter Rail, Nashua Minimum Commuter Rail, Intercity 8, Expanded Base, Bus on Shoulder, and Expanded Bus on Shoulder.

2.4.5 Commuter Rail – Manchester Regional and Nashua Minimum

The Study team revisited the operating conditions for each of the three remaining rail options in meetings with PAR, MassDOT, MBTA, and NHDOT and was able to refine the service characteristics based on their feedback. The O&M costs evolved over the course of the Study's preliminary stages, but did not change significantly. The total number of weekday vehicle miles and weekday revenue miles changed slightly as options were refined. Two additional elements where changes were applied are in the calculation of unit costs and fare revenue. The operating cost data for the commuter rail options were updated to 2012 National Transit Database (NTD) figures from the 2009 NTD values. These values were used to describe each service option to estimate O&M cost drivers for each commuter rail option: train miles, rolling stock fleet size (locomotives and coaches), and track miles.

2.4.6 Intercity Rail

The Intercity 8 service option that advanced through preliminary screening was developed to the same level of detail as the commuter rail service options, including estimates of daily train miles, rolling stock requirements, track miles required, number and location of stations, and schedules of service.

The most recent data on the *Downeaster* service indicated that it costs roughly $36 per train mile to operate. This metric is roughly equivalent to the costs applied for Midwestern and New York/Vermont services reviewed in the studies recommended by Amtrak. Using the simple cost of $36 per train mile, the preliminary estimates of operating cost were derived for the three intercity service options.

2.4.7 Commuter Bus

Weekday service schedules developed for each of the three commuter bus options did not change after the preliminary screening. The estimates of vehicle requirements and revenue miles, however, did change slightly as the options were refined.

2.4.8 Summary of Final Estimates of Annual O&M Costs

In summary, the preliminary estimates of annual O&M costs for the rail and bus service options are found in Table 2.12.

Table 2.12: Final Estimates of Annual O&M Costs (In Millions, 2012$)

Service Option	Total
Commuter Rail Options	
Manchester Regional	$11
Nashua Minimum	$4
Intercity Rail Options	
Intercity 8	$8
Bus Service Options	
Expanded Base	$3
Bus on Shoulder	$0
Expanded Bus on Shoulder	$3

2.5 Ridership

Opening day forecasts on the Manchester Regional and Nashua Minimum Commuter Rail alternatives are presented below in Tables 2.13 and 2.14. The model results are presented with a forecast value and an upper and lower bound that are the 95 percent confidence interval around the forecast value. It is important to note that, as with all forecasts, the predictions are not a single value but are a range of possible values.

Table 2.13: Manchester Regional Daily Boarding Estimates

Station	Forecast	Lower Bound	Upper Bound
Manchester	270	180	390
Bedford/MHT	280	230	350
Nashua	420	330	540
South Nashua	590	440	800
TOTAL	**1,560**	**1,180**	**2,090**

Table 2.14: Nashua Minimum Daily Boarding Estimates

Feeder Bus Weight	Forecast	Lower Bound	Upper Bound
South Nashua	590	450	770

The estimated model predicts the daily boards (Table 2.15) for each proposed station. These boards represent one-half of a daily round trip. To convert these boarding data to daily ridership a factor of two is applied to account for the second half of the round trip.

Table 2.15: Daily Ridership Estimates

Alternative	Ridership	Lower Bound	Upper Bound
Manchester Regional Commuter Rail	3,130	2,350	4,170
Nashua Minimum Commuter Rail	1,170	890	1,540

Executive Summary

Building upon the land use and economic development analyses prepared for the New Hampshire Capitol Corridor Alternatives Analysis (AA) Transit Study, Cambridge Systematics has conducted an economic development assessment aimed at estimating the potential benefits associated with the set of final build alternatives in the corridor. The assessment examines two types of economic benefit. First is the amount of new development that might occur around new station areas. Second is the impact of this new development plus the investment in new or upgraded transit infrastructure measured in terms of employment and economic output in the Capitol Corridor region. This assessment does not attempt to capture every type of economic benefit that might be realized from implementation of the alternatives; rather it focuses on these two key benefits measures to help identify differences among the alternatives. As a consequence, this assessment estimates benefits associated with the three rail alternatives, all of which provide new permanent infrastructure such as stations. In contrast, none of the bus alternatives involve new stations, and are therefore not expected to generate the development-based economic benefits measured in this assessment.

1.1 Economic Benefits of Transit Investment

The Study team examined the literature and findings from recent studies of similar regional transit enhancement projects. Numerous studies have identified a net positive benefit of fixed-guideway transit investment to the regional economy, as a result of travel time savings and congestion reduction, expanded access to jobs and workforce, and new development attracted to station areas. Studies have also found a positive impact of transit on property values in station areas. While only a few studies have specifically examined commuter rail, evidence from other rail system expansions in the greater Boston region similarly suggests that transit investment will have a positive effect on the communities it serves. There are very few studies of the economic impacts of bus enhancement projects, and none which suggest that the kinds of enhancements contemplated in the Capitol Corridor would help catalyze new, more intense development.

1.2 Station Area Economic Development

The Study team conducted interviews with local stakeholders to gather information on the impact the different transit alternatives could have in bringing about new development over the next 20 years. Based on the expressed opinions of the set of stakeholders interviewed, there was general consensus that commuter rail service to Boston is important for the future development of southern New Hampshire. While some high tech, residential and institutional development is currently occurring near several of the stations, respondents felt that this development would be difficult to maintain or boost (particularly in the case of high tech) without rail enhancements to attract the type of workers necessary to facilitate growth, namely a younger demographic looking for urban to semi-urban living with walkable amenities.

The Study team also assembled data on land use and zoning to evaluate the potential impact of the project alternatives on development and redevelopment. This potential was measured in terms of commercial square footage (office and retail) and housing units for the different alternatives. The Study team estimated the following illustrative impacts, as summarized in Table ES-1:

- **Manchester Regional Commuter Rail** – This alternative, serving four stations in Nashua and Manchester at a moderate to high frequency, would have the greatest benefit. It has the potential to generate over 3,600 new residential units and nearly 2 million square feet of commercial space supporting over 5,600 new jobs by the year 2030.
- **Nashua Minimum Commuter Rail** – This alternative, serving one station in Nashua at moderate to high frequency, could potentially generate about 1,100 new residential units and 930,000 square feet of commercial space supporting 2,500 new jobs by the year 2030.
- **Intercity 8** – This alternative, with four trains per day serving Nashua, Manchester, and Concord, could potentially generate about 1,600 new residential units and over 800,000 square feet of commercial space supporting 2,500 new jobs by the year 2030. While the same number of stations would be served as for the Manchester Regional Commuter Rail, impacts per station would be somewhat lower due to the lower service frequency.
- **Bus Alternatives** – Capital improvements associated with the bus alternatives range from additional buses to operate increased levels of service, to roadway improvements that would help buses bypass congestion by operating on the shoulder along I-93 south of I-495. These alternatives differ from the three rail alternatives above, in that they will not include new stations around which transit oriented development might occur. For this reason, and notwithstanding other benefits associated with bus improvements such as reductions in travel times, the kinds of economic development benefits documented in this assessment are not expected to occur for the bus alternatives. This is supported both by the literature and was the consensus opinion of the stakeholders interviewed.

Table ES.1: Total Station Area Development Potential by Alternative

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Manchester Regional Commuter Rail	1,898,000	3,600	5,600
Nashua Minimum Commuter Rail	930,000	1,100	2,500
Intercity 8	819,000	1,600	2,500
Intercity Bus	0	0	0
No Build	0	0	0

Note: residential units and jobs rounded to the nearest hundred

The Study team used these data to measure potential at the individual stations. The analysis shows that the commuter rail alternatives consistently perform better from both a jobs and development perspective. The Concord location could potentially generate the highest square feet of commercial space in either scenario, either downtown Manchester location could potentially generate the greatest

number of residential units in either scenario, and the Nashua Spit Brook Road location had the potential to support the greatest number of jobs. See summary in Tables ES.2 and ES.3.

Table ES.2: Summary – Commuter Rail Development Potential in Each Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Manchester – Bridge Street	587,000	1,410	2,040
Manchester – Granite Street*	567,000	1,360	1,970
Bedford – Manchester-Boston Regional Airport (Bedford – MHT)*	245,000	0	720
Nashua – Crown Street*	155,000	1,110	410
Nashua – Spit Brook Road*	930,000	1,120	2,480
Nashua – Pheasant Lane Mall	116,000	0	280

**Included in summary totals for Manchester Regional Commuter Rail alternative*

Table ES.3: Summary – Intercity 8 Development Potential in Each Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Concord – Stickney Avenue*	335,000	400	890

Nashua – Pheasant Lane Mall	58,000	0	140

**Included in summary totals for Intercity 8 alternative*

1.3 Regional Economic Benefits

The economic modeling tool IMPLAN was used to estimate the broader economic benefits to the southern New Hampshire region of each Capitol Corridor project rail alternative and its associated station area development. IMPLAN is a widely accepted and utilized model that shows how an investment made in particular sectors of the economy – in this case public transportation and station area development – then flow through and benefit other sectors, for a total estimate of economic activity generated by that original investment. For this assessment, the following regional economic benefits were evaluated:

- Short-term benefits as a result of spending on construction of rail improvements in New Hampshire
- Long-term benefits as a result of the attraction of more residents and jobs to southern New Hampshire; these include benefits related to the construction of new real estate in station areas, as well as ongoing benefits from new worker earnings reinvested in the local economy

Benefits of time savings to travelers cannot be directly monetized in this type of economic analysis. However, they are capitalized into land values, and therefore are indirectly considered through the real estate effects. Benefits of the bus alternatives were not estimated, as these alternatives would involve minimal capital investment, and the literature, stakeholder interviews, and the Study team's professional experience suggest that associated development impacts would also be minimal.

The economic modeling provides the following illustrative regional impacts, as summarized in Tables ES.4 and ES.5:

- **Manchester Regional Commuter Rail** – This alternative has moderate construction impacts and the highest development-related impacts. It has the potential to generate 230 new jobs over the construction period (2019-2022), about 3,390 jobs related to new real estate development between 2021 and 2030;[1] and about 1,730 new jobs annually in 2030 and beyond (with benefits beginning to accrue after 2021) due to reinvested worker earnings. Real estate development would add $1.2 billion to the state's output between 2021 and 2030, with reinvested earnings adding $220 million per year beyond 2030.
- **Nashua Minimum Commuter Rail** – This alternative generates the lowest construction and development impacts since only one new station is located in New Hampshire. It has the potential to generate 80 new jobs over the construction period (2019-2022), over 850 jobs related to new real estate development between 2021 and 2030; and nearly 380 new jobs annually in 2030 and beyond due to reinvested worker earnings. Real estate development would add $260 million to the state's output between 2021 and 2030, with reinvested earnings adding $50 million per year beyond 2030.
- **Intercity 8** – This alternative generates the greatest construction impacts but lesser development-related impacts compared to the Manchester Regional Commuter Rail alternative, because of its lower service frequency. It has the potential to generate 350 new jobs over the construction period (2019-2022), 2,460 jobs related to new real estate development between 2021 and 2030; and 1,140 new jobs annually in 2030 and beyond (with benefits beginning to accrue after 2021) due to reinvested worker earnings. Real estate development would add $750 million to the state's output between 2021 and 2030, with reinvested earnings adding $140 million per year beyond 2030.

Table ES.6 shows the impacts on state and local tax revenues by alternative. Project construction would add up to $2.1 million, real estate development up to $43 million over the 2021-2030 timeframe, and reinvested worker earnings up to $13 million annually in 2030 and beyond.

[1] A new "job" over a multi-year period is really a "job-year", i.e., 3,400 jobs over a 10-year period is equivalent to 340 jobs that each continue for the entire 10-year period

Table ES.4: Impacts on Employment (Jobs) by Alternative*

Alternative	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	230	3,390	1,730
Nashua Minimum Commuter Rail	80	850	380
Intercity 8	350	2,460	1,140
Intercity Bus	0	0	0
No Build	0	0	0

**These impacts are in addition to the new jobs located in station areas as shown in Table ES-1.*

Table ES.5: Impacts on Output (Gross Regional Product) by Alternative (In Millions, 2014$)

Alternative	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	$70	$1,200	$220
Nashua Minimum Commuter Rail	$20	$260	$50
Intercity 8	$100	$750	$140
Intercity Bus	0	0	0
No Build	0	0	0

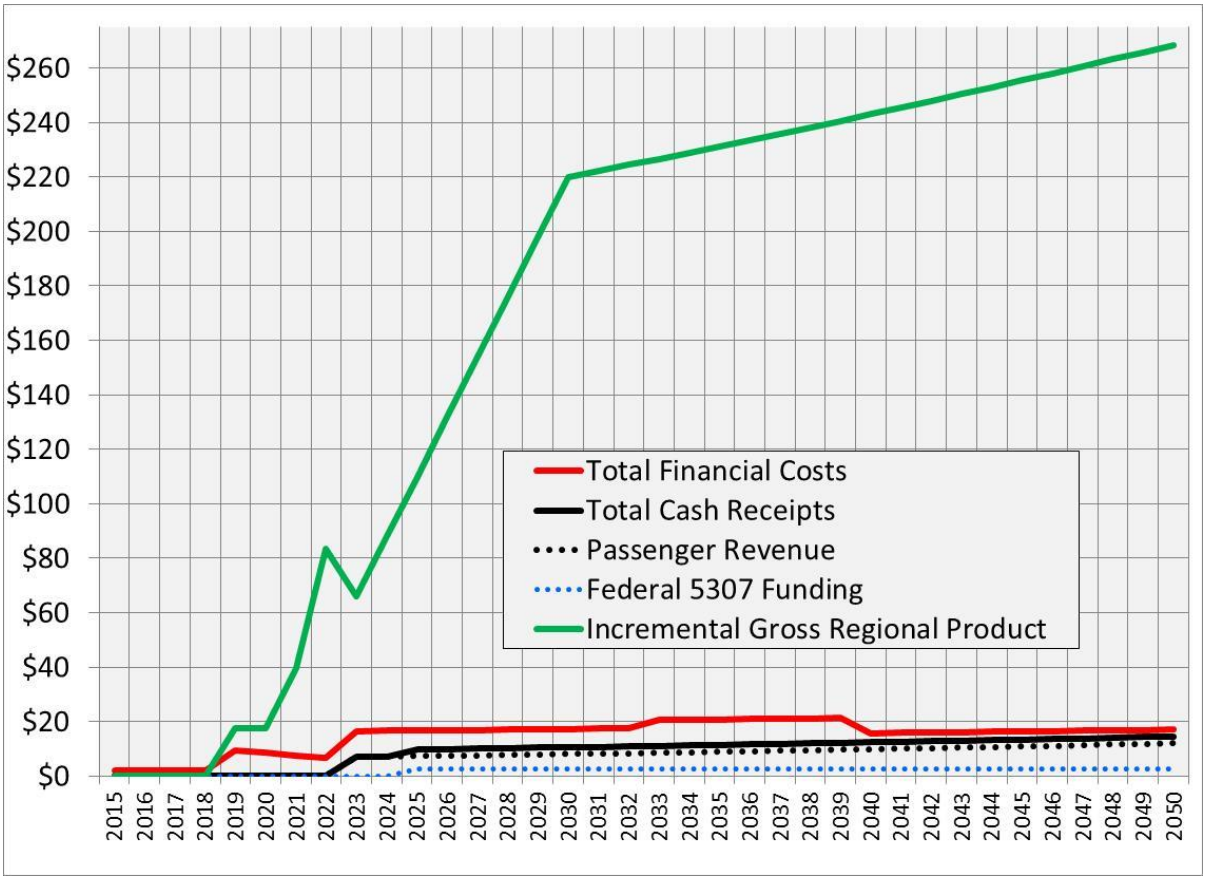
Table ES.6: Impacts on State and Local Tax Receipts by Alternative (In Millions, 2014$)

Alternative	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	$1.3	$43.3	$13.1
Nashua Minimum Commuter Rail	$0.5	$9.3	$2.9
Intercity 8	$2.1	$27.1	$8.7
Intercity Bus	0	0	0
No Build	0	0	0

1.4 Time Line of Costs, Revenues, and Economic Benefits

The Study team integrated the forecast stream of economic benefits with the forecast streams of costs and revenues to derive a timeline of costs, revenues, and economic benefits forecast to result from a state investment in the Manchester Regional Commuter Rail alternative. Figure ES.1 shows a 35-year time horizon with forecast annual costs, cash receipts, and economic benefits for each future year**. All costs, revenues, and benefits are shown in 2014 dollars.**

Figure ES.1: Forecast Annual Costs, Revenues, and Economic Benefits



With an allowance for capital renewal, the forecast cash receipts (fare revenue and federal formula funds) over the next 35 years approach, but do not fully cover, the annual financial costs for engineering, debt retirement, operating costs, and asset renewal. However, forecast economic benefits in terms of employee wages, business earnings, and tax receipts clearly exceed the annual financial costs of the service. While the forecast economic benefits are estimates, if only half that forecast growth in regional economic activity is achieved, the benefits would still outweigh the net financial liabilities by a large margin.

It is notable that the forecast regional economic activity grows to include $13 million in annual tax revenue by 2030. If New Hampshire officials can fashion a mechanism to capture a fraction of this new tax revenue to support the rail service, a self-sustaining financial path forward could be achievable.

2 Economic Benefits of Transit Investment

The objective of this task was to document the potential benefits of the New Hampshire Capitol Corridor alternatives. The assessment included both quantitative and qualitative findings of economic benefits resulting from improved transit services. Two types of benefit were evaluated:

- Station area economic development benefits, measured through new development and increased population and employment, which supports community development/ revitalization and the local tax base
- Net regional benefits, including jobs, income, and regional product, resulting from increased population and workforce in southern New Hampshire, traveler benefits, and the short-term benefits from constructing the project

Given that this assessment was focused primarily on new development that could be spurred by construction of new transit facilities such as stations, the kinds of economic benefits estimated will not be expected to occur for the three bus alternatives. Capital improvements associated with those alternatives range from additional buses to operate increased levels of service, to roadway improvements that would help buses bypass congestion by operating on the shoulder along I-93 south of I-495. In other words, the bus alternatives differ from the three rail alternatives, in that they will not include new stations around which Transit-Oriented Development (TOD) might occur. For this reason, and notwithstanding other benefits associated with bus improvements such as reductions in travel times, the kinds of economic development benefits documented in this assessment are not expected to occur for the bus alternatives. This is supported by the literature and was the consensus opinion of the stakeholders interviewed.

Furthermore, while the focus of this assessment was on new benefits directly related to transit enhancements, it is worth noting that the relocation of economic activity can also lead to net benefits. For instance, the relocation of businesses and jobs into more compact, TOD patterns may increase transportation efficiencies while decreasing the social and environmental costs of sprawling development patterns. These types of indirect benefits are more difficult to quantify and beyond the scope of this assessment, but are nonetheless important to consider.

The remainder of this section provides a qualitative overview of the various ways in which a transit investment in the Capitol Corridor is expected to benefit the local and regional economy. Section 2.0 describes a quantitative estimate of local (station area) development impacts. Section 4.0 describes a quantitative estimate of the net regional benefits developed using the IMPLAN economic model.

2.1 Regional Economic Benefits

Transit investments can add regional value in the following ways:

- By reducing time and cost for roadway and transit travelers, as well as freight traffic through reduced traffic congestion; these time and cost savings may result in business cost savings and productivity improvements
- By attracting new businesses or residents to the region, or encouraging existing businesses to expand, because of improved transportation infrastructure

These benefits can lead to increases in jobs, regional product, and personal income. According to a recent Transit Cooperative Research Program (TCRP) publication, nearly 15,900 jobs are supported for a year for each billion dollars of spending on public transportation *capital,* and over 24,200 jobs are supported for a year for each billion dollars of annual spending on public transportation *operations*.[2]

The benefits of transportation improvements can also be reflected in higher property values, which add to the local tax base.

Several research efforts have estimated the benefits of transit investment in different cities. For example, a 2012 study developed by Cambridge Systematics for the Itasca Project in the Twin Cities region[3] found that build-out of a regional transit network through year 2030 would yield the following:

- A 25 percent increase in access to workforce within a 30-minute travel time
- Direct benefits of $6.6 to $13.9 billion accruing over the 2030-2045 period (including travel time savings, vehicle operating cost savings, and other benefits)
- Over 30,000 full-time equivalent jobs and $4.3 billion in gross regional product (GRP) from construction
- Indirect benefits of an additional 3,500 to 8,495 jobs by 2045 and expansion of the regional economy up to $1.4 billion

A 2005 study for Envision Utah[4] of transit improvements in the Salt Lake City region estimated annual direct benefits to users of $220 million, an increase in employment of 1,400 jobs, an increase in net personal income of $105 million, and an increase in GRP of $140 million from efficiency gains for business travel.

[2] Economic Impact of Public Transportation Investment, EDRG, Inc., 2014. Includes all modes of public transportation, including bus and rail, but does not differentiate benefits among them. Benefits are estimated in terms of direct spending (i.e., capital and operations and maintenance [O&M] costs), but also in terms of travel time and access improvements and economic impacts, such as increases in property values.

[3] *Regional Transit System Return on Investment Assessment*. Itasca Project, 2012

[4] Economic Impacts of Expanding Public Transportation in the Wasatch Front Region. Envision Utah Project, 2005

A 1995 light rail study conducted by the Greater Hartford Transit District[5] found that transit investment could create as many as 2,246 jobs and $34.3 million change in real GRP by 2030.

A 1998 study of light trail transit investment in Rochester, New York[6] estimated that the project would add nearly $54 million to GRP during construction, up to $7 million annually to GRP over life of the project, and create 111 permanent jobs by 2025 with an annual personal income of $9.9 million, not including O&M jobs required by light rail transit.

2.2 Station Area Development Benefits

2.2.1 Property Values

A considerable amount of research and literature across the U.S. has examined the impacts of transit systems on property values for both residential and commercial development. Numerous studies have found a positive link between rail transit and property values. The evidence for commuter rail systems is more limited, but also positive. While U.S. bus rapid transit (BRT) systems, which share characteristics with fixed guideway systems such as dedicated rights-of-way, stations with passenger amenities, level boarding, and frequent service, are showing impacts to development and property values, there are no studies providing similar evidence for standard bus service.

Studies quantifying property value increases in the Boston area found the following conclusions:

- Armstrong (1994) found an increase in single-family residential property values of approximately 6.7 percent by virtue of being located within a community having a commuter rail station. At the regional level there appears to be a significant impact on single-family residential property values resulting from the accessibility provided by commuter rail service.[7]
- Where commuter rail service was restored since 1994 in Brockton, Newburyport, and Worcester, real estate values climbed faster than state and county averages by most measures, in some cases much faster.[8]

Studies in other areas have found similar benefits. Here are some examples:

- In the New York region, Cambridge Systematics performed an analysis of the overall property value benefit of a commuter rail system to the counties served by the system. The analysis found that between seven and 15 percent of the value of a home may be due to proximity to rail stations.

[5] *Griffin Line Major Investment Study Economic Impact Analysis*, 1995
[6] *Rochester LRT Economic Development Feasibility Study*, Wilbur Smith Associates with BRW, Erdman Anthony, and Fisher Associates, 1998
[7] Armstrong, Robert J., "Impacts of Commuter Rail Service as Reflected in Single-Family Residential Property Values," Transportation Research Record, 1466 (1994): 88-97
[8] Howe, Peter J. "New rail service to Hub called economic boon: Three cities point to rise in real estate values." *Boston Globe*, February 17, 2008

- A study of the Coaster commuter rail line in San Diego found a residential premium of 17 percent for properties within one-half mile of stations.[9]
- A 1997 study by Gruen Gruen + Associates found that proximity to Chicago Transit Authority heavy rail and Metra commuter rail stations positively affects the value of single family homes, with the price of a single-family house located 1,000 feet from a station averaging 20 percent higher than a comparable house located a mile away.

2.2.2 New Development

Several studies have demonstrated that under the right circumstances, rail transit stations can serve as a catalyst or focal point for growth. Here are some examples:

- A 2006 study by the Kennedy School of Government at Harvard University on the impacts of commuter rail in Massachusetts concluded that commuter rail is most likely to impact land use patterns when it is explicitly and clearly linked to local and regional policies for land use and development.
- Opening of the Massachusetts Bay Transportation Agency's (MBTA's) Greenbush line has supported new residential and mixed-use developments in Kingston, Scituate, and Weymouth.[10]
- The California Intercity High Speed Rail Commission projected land value increases between 0 and 20 percent, and between $1.7 and $2.0 billion of development attributable to high speed rail (HSR). The study also found that land within 1,000 feet of HSR alignment, but outside of station radius would remain stable or decrease slightly depending on future conditions.[11]
- Transit-oriented planning and rezoning, in conjunction with related development activities and anticipation of new LRT service, has helped spur 46 new development projects in Charlotte's South Corridor LRT station areas.
- In Washington, D.C., the Metrorail system generated more than $15 billion in development through the year 2000. At least 52 joint development projects with a market value of $4 billion were constructed around Metrorail stations, generating an estimated 50,000 new transit riders and over 25,000 jobs.

2.2.3 Transit Supportive Factors

Numerous studies have concluded that these types of successful development outcomes in transit station areas, with associated gains in ridership and economic benefits, require the presence of other supportive factors. These factors are summarized in a report for the TCRP (Cervero et al, 2004):

[9] Cervero, R., and M. Duncan. "Effects of Light and Commuter Rail Transit on Land Prices Experiences in San Diego." National Association of Realtors and Urban Land Institute, 2002

[10] Robert Preer, "Now arriving: Development spurred by Greenbush line South Shore towns rezone land to concentrate building near new stations," Boston Globe, April 16, 2006; and "Family-Friendly Housing." Editorial, *Boston Globe*, April 25, 2007

[11] Economic Impact and Benefit/Cost of High Speed Rail for California, Economic Research Associates, 1996

- Local comprehensive plans and zoning ordinances must promote development with transit-supportive characteristics, including higher-density, mixed-use, and pedestrian-oriented development.
- Public assistance with land assembly, contaminated site cleanup, infrastructure finance, or other factors may sometimes be needed to leverage private investment.
- Timely processing of development permits, and certainty on the types of allowable development, are extremely important.
- Station area planning is another critical activity to address neighborhood concerns about development and create greater certainty for developers.

Many of these type of transit supportive development policies, including higher-density mixed-use zoning, flexible parking requirements, development agreements for expedited permitting, and pedestrian-oriented development are in place for the Concord and downtown Manchester sites, while TOD supportive zoning enhancements are recommended for the Crown Street and Spit Brook Road station sites in Nashua.[12] Combined with a favorable regional economic climate, these factors suggest that the New Hampshire Capitol Corridor could act as an organizing force for new development.

3 Station Area Development Potential

To assess the potential economic benefits of the alternatives, an illustrative analysis was conducted of the station area development potential for the seven proposed station areas. This analysis did not identify quantifiable development or other economic benefits associated with any of the three bus alternatives – Expanded Base, Bus on Shoulder, or Expanded Bus on Shoulder. As explained above, this is because there are no new permanent infrastructure improvements, such as stations, that would be constructed in New Hampshire. While there are other benefits that would be expected as a result of these bus improvement alternatives, such as increased mobility options, improved bus travel time and related increases in ridership, and lowered carbon footprints per passenger mile, neither the literature nor interviews with corridor stakeholders support meaningful increases in economic activity for the final set of bus alternatives as compared to the fixed guideway commuter rail and intercity rail alternatives.

Literature examining benefits of intercity bus and motor coach services generally cites tourism as the primary industry served. For a predominantly intercity commuter service, such as the services that are contemplated in the Capitol Corridor, benefits would be expected to include increased mobility options and out-of-pocket savings for riders, decreased travel times, and lower emissions. However, no studies have specifically addressed economic development benefits of this type of bus service.[13,14,15,16,17] Rather,

[12] Land Use & Economic Development Analysis, Capitol Corridor Rail & Transit Alternatives Analysis (Parts A & B), URS, 2014

[13] However, as noted above, direct bus capital spending will generate economic benefits, commensurate with the level of spending. The majority of those benefits, for example related to bus manufacturing, will accrue to the locations where the manufacturing activities take place.

[14] *The Economic Impacts and Social Benefits of the U.S. Motorcoach Industry*, Nathan and Associates, Inc., December 2008

[15] *Economic and Community Benefits of Local Bus Transit Service*, Michigan Department of Transportation, July 2010

economic benefit studies have been focused on fixed guideway infrastructure that provides permanent stations and other facilities around which TOD can occur. This type of development impact, which is not comparable for bus, can generate direct capital and indirect consumer spending, which, in turn, results in economic benefits to local and regional economies.

Finally, the extensive national experience of Study team members – and other transit industry experts – on both bus and rail projects indicates that well-designed rail projects can lead to the kinds of desirable economic impacts estimated in this assessment, while bus service of the type envisioned in the Capitol Corridor would not.

3.1 Approach

The Study team assembled land use, parcel and zoning data, where available, for the potential station area sites in Nashua, Manchester, and Concord. A quantitative and qualitative approach was used to assess the amount of additional development potential that might be reasonably expected for the proposed station areas included in each of the corridor transit alternatives. Underdeveloped and/or vacant parcels within a one-half mile radius of each station area were considered most likely for new development. Development potential was calculated using floor area ratios (FAR) permitted under existing zoning, combined with assumptions about the likely mix of uses for each station area. This potential was measured in terms of commercial square footage (office and retail) and housing units for the different alternatives. For residential development, conversion factors of 1,250 square feet per residential unit and two persons per unit were applied as being typical for TOD style multi-family development. For commercial development, 250 square feet per office job and 750 square feet per retail job were assumed.

This analysis assumed that the development potential for each alternative would be fully realized by 2030. A No Build scenario was also considered.

3.2 Interviews

The Study team conducted stakeholder interviews with local and regional planners (4), developers (1), chamber of commerce members (2), and local planning board members (1) to help inform the necessary assumptions, such as existing development conditions and trends and the degree of impact the different transit alternatives could have in bringing about new development for each of the potential station area sites over the next 20 years. Participants, who were selected based on their knowledge of the development climate in the Southern New Hampshire, were asked 11 questions beginning with their level of involvement with the Capitol Corridor Alternatives Analysis (AA) Study and their detailed knowledge of economic development conditions in specific station areas. Participants were asked for their professional opinions as to the development impact that might occur under the different

[16] Kansas Statewide Intercity Bus Study, Kansas Department of Transportation, December 2012
[17] The American Bus Association Economic Impact Study, ABA, January 2013

alternatives, including commuter rail service of 16-34 trains per day, intercity rail service with four trains per day, and the intercity bus alternatives as "enhanced" bus service. Participants were also asked for their professional opinions of what development might look like over the next 20 years *without* the project. Based on participant responses, the Study team assumed *full* development potential would be achieved with the commuter rail alternative, but only *half* that potential would be realized under an intercity rail alternative. There was general consensus that the intercity bus alternative would do little to boost economic development, as buses are subject to existing roadway congestion issues. Similarly, while there currently is some high tech, residential, and institutional development occurring near several of the station area sites, there was general consensus among interview participants that this economic development would be difficult to maintain or boost (particularly in the case of high tech) without rail enhancements to attract the type of workers necessary to facilitate growth, namely a younger demographic looking for urban to semi-urban living with walkable amenities. One respondent also indicated rail was just as important to retain existing workers in New Hampshire that may be otherwise attracted to the transit amenities and walkable lifestyle found farther south in the Boston area.

3.3 Station-by-Station Assessment

3.3.1 Concord – Stickney Avenue

The Stickney Avenue station area site was identified as suitable for TOD, primarily due to the mixed use and high-density residential allowances and flexible parking requirements under zoning. Parcels considered most likely to develop or redevelop due to transit alternatives were primarily located within the Opportunity Corridor Performance (OCP) District, the Gateway Performance District (GWP), and the Central Business Performance (CBP) District, all with a FAR of 2. The potential development/ redevelopment area is large (1.7 million square feet), so the analysis conservatively assumes a FAR of 1.0 as an average across the sites. The analysis also assumed a 60/40 residential/commercial mix of uses (built square footage) with commercial split evenly between office and retail. See Table 3.1.

Table 3.1: Development Potential in Concord Stickney Avenue Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Commuter Rail	n/a	n/a	n/a
Intercity Rail	335,000	400	890
Intercity Bus	0	0	0
No Build	0	0	0

3.3.2 Manchester – Bridge Street

Similar to the Granite Street site, there is little vacant land within this station area. Parcels considered likely to redevelop are predominantly located within the Central Business (CBD, FAR 5) and residential (R-3, FAR 0.75) districts. The Study team assumed a majority of floor area (75 percent) would be developed with residential use, with most of the remaining being office. See Table 3.2.

Table 3.2: Development Potential in Manchester Bridge Street Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Commuter Rail	587,000	1,410	2,040
Intercity Rail	294,000	710	1,020
Intercity Bus	0	0	0
No Build	0	0	0

3.3.3 Manchester – Granite Street

There is little vacant land within the Granite Street station area. Due to the transit supportive zoning, however, there are many underutilized parcels that could potentially redevelop in conjunction with the proposed rail service enhancements. Parcels considered likely to redevelop are predominantly located within the Central Business District (CBD, FAR 5) with some intensification possible in the residential (R-3, FAR 0.75) district. This area is also considered suitable for TOD due to its high-density residential and commercial allowances under zoning. The Study team assumed a majority of floor area (75 percent) would be developed with residential use, with most of the remaining being office. See Table 3.3.

Table 3.3: Development Potential in Manchester Granite Street Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Commuter Rail	567,000	1,360	1,970
Intercity Rail	284,000	680	980
Intercity Bus	0	0	0
No Build	0	0	0

3.3.4 Manchester Airport (Bedford/MHT)

Given the relatively low residential and commercial densities proximate to the proposed station area, this site has the least amount of development potential; however, there was a general consensus among interview participants that rail connectivity to the airport was critical for regional economic development. The analysis focused on land presently zoned industrial and an assumed FAR of 0.15 to 1.0 developed with office and retail uses. This analysis did not consider parcels likely to redevelop but not vacant in this station area. See Table 3.4.

Table 3.4: Development Potential in Manchester Airport (Bedford/MHT) Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Commuter Rail	245,000	0	720
Intercity Rail	123,000	0	360
Intercity Bus	0	0	0
No Build	0	0	0

3.3.5 Nashua – Crown Street

The predominant zoning for this station area is multi-family residential (R-B, FAR 0.5) and General Industrial (GI, FAR 2). This analysis utilized FAR for these districts and an assumed development would be predominantly residential with a small amount of commercial use. A mixed-use or TOD supportive overlay in this area would boost development potential, given the amount of vacant land suitable for development. This analysis did not consider parcels likely to redevelop but not vacant in this station area, as in the near-term at least such redevelopment is expected to be modest. See Table 3.5.

Table 3.5: Development Potential in Nashua Crown Street Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Commuter Rail	155,000	1,110	410
Intercity Rail	77,000	560	210
Intercity Bus	0	0	0
No Build	0	0	0

3.3.6 Nashua – Spit Brook Road

The predominant zoning for vacant parcels within this station area are Highway Business (HB, FAR 0.75) and General Business (GB, FAR 1.25). This analysis assumes a 60/40 residential to commercial mix with an even split between retail and office uses. A mixed use or TOD overlay for this station area, including higher allowable densities for the large undeveloped parcel adjacent to the station site, could boost the development potential of this station area significantly. See Table 3.6.

Table 3.6: Development Potential in Nashua Spit Brook Road Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Commuter Rail	930,000	1,120	2,480
Intercity Rail	465,000	560	1,240
Intercity Bus	0	0	0
No Build	0	0	0

3.3.7 Nashua – Pheasant Lane Mall

The limited vacant land near this station area is zoned Highway Business (HB, FAR 0.75). This analysis assumed the land is developed for commercial uses with a greater emphasis on retail. The current low density zoning and development configuration of this site remain limited for economic development through rail and transit enhancements. See Table 3.7.

Table 3.7: Development Potential in Nashua Pheasant Lane Mall Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Commuter Rail	116,000	0	280
Intercity Rail	58,000	0	140
Intercity Bus	0	0	0
No Build	0	0	0

3.3.8 Station Area Summary

Tables 3.8 and 3.9 provide a summary of the economic benefits at each station.

Table 3.8: Summary – Commuter Rail Development Potential at Each Station Area

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Concord – Stickney Avenue	n/a	n/a	n/a
Manchester – Bridge Street	587,000	1,410	2,040
Manchester – Granite Street	567,000	1,360	1,970
Bedford – MHT	245,000	0	720
Nashua – Crown Street	155,000	1,110	410
Nashua – Spit Brook Road	930,000	1,120	2,480
Nashua – Pheasant Lane Mall	116,000	0	280

Table 3.9: Summary – Intercity 8 Development Potential at Each Station

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Concord – Stickney Avenue	335,000	400	890
Manchester – Bridge Street	294,000	710	1,020
Manchester – Granite Street	284,000	680	980
Bedford – MHT	123,000	0	360
Nashua – Crown Street	77,000	560	210
Nashua – Spit Brook Road	465,000	560	1,240
Nashua – Pheasant Lane Mall	58,000	0	140

3.4 Combined Economic Benefits of Alternatives

Based on the analysis of the individual station areas, the Study team estimated the following illustrative, cumulative economic development potential for the various project alternatives:

- **Manchester Regional Commuter Rail** – Commuter rail benefits for the Manchester Granite Street, Manchester Airport (Bedford/MHT), Nashua Crown Street, and Spit Brook Road station locations
- **Nashua Minimum Commuter Rail** – Commuter rail benefits for the Spit Brook Road station only
- **Intercity 8** – Intercity rail benefits for the Concord, Manchester Granite Street, Manchester Airport (Bedford/MHT), and Nashua Crown Street station locations

The greatest benefit, as expected, is for the Manchester Regional Commuter Rail alternative serving four stations at a moderate to high frequency. Manchester Regional Commuter Rail has the potential to generate over 3,600 new residential units and nearly two million square feet of commercial space supporting over 5,600 new jobs. The second greatest benefit is for the Intercity 8 alternative, which serves the most stations, but with more limited impact due to its low frequency of service. The Nashua Minimum Commuter Rail alternative provides frequent service, but only to one station in New Hampshire. See Table 3.10.

Table 3.10: Total Development Potential by Alternative

Alternative	Commercial (Square Feet)	Residential (Units)	Jobs
Manchester Regional Commuter Rail	1,898,000	3,600	5,600
Nashua Minimum Commuter Rail	930,000	1,100	2,500
Intercity 8	819,000	1,600	2,400
Intercity Bus	0	0	0
No Build	0	0	0

Note: residential units and jobs rounded to the nearest hundred

3.5 Limitations of the Analysis

This analysis was intended to expand upon the Land Use & Economic Development Analysis (January, 2014) of the Capitol Corridor AA Study,[18] which detailed the transit supportive conditions of each of the seven proposed station areas. It provides illustrative estimates of the potential station area economic development that could be leveraged by the proposed transit alternatives. Parcel level data and existing development conditions in a GIS format are critical in determining new development potential. This information was not readily accessible for each of the station areas. Absent this information, assumptions were rooted in local knowledge about the likelihood of development and/or redevelopment of certain parcels informed the analysis. In addition, assumptions about the likely mix of uses for each station area were highly malleable resulting in slightly variable development projections.

[18] Not included as an appendix to the AA Final Reports; available under separate cover

Jobs and residents per square foot of development may also vary. Development potential projections were based only on FAR under existing zoning. Other dimensional requirements that may influence development potential (such as building height, open space, or parking) were not considered in the analysis, and zoning could be changed in the future. Long-term development potential could be greater than estimated here, if lower-value properties were redeveloped at higher intensities. Finally, as explained in this section, the types of economic impacts examined would not be expected for any of the bus alternatives; however, other benefits could be expected as a result of the improvements in bus travel time, but were not captured in this assessment.

4 Regional Economic Benefits

4.1 IMPLAN Analysis

The economic modeling tool IMPLAN was used to estimate the broader economic benefits to the Southern New Hampshire region of each Capitol Corridor project alternative. These benefits are in addition to the direct attraction of new station area jobs and residents. IMPLAN is a widely accepted and utilized model that shows how an investment made in one sector of the economy – in this case transportation – then flows through and generates benefits in other sectors for a total estimate of economic activity in a region.

4.1.1 Scope of the Analysis

The following regional economic benefits were evaluated:

- Short-term benefits as a result of spending on construction of rail improvements and new station area development in New Hampshire
- Long-term benefits as a result of the attraction of more residents and jobs to Southern New Hampshire, through worker earnings that are reinvested in the state's economy

Direct benefits to travelers (time and cost savings) were not explicitly included in the analysis. Economic modeling tools such as IMPLAN are designed to track monetary flows through the economy. Time savings can only be monetized if they lead to direct cost savings, such as in the case of "on-the-clock" business or freight travel. Personal time savings benefits (for commuting or other personal travel) cannot be directly monetized in this way. However, they may be capitalized into land values, and therefore were indirectly considered through the real estate effects included in this analysis. While commuting time savings benefits were also sometimes assumed to benefit businesses by increasing productivity or reducing costs, in this case, most of the transit riders will be commuters to Boston, and, therefore, the businesses benefiting will not be within the southern New Hampshire Study area.

Cost savings to travelers using the commuter rail also were not included. While travelers would save out-of-pocket expenses on gasoline, vehicle maintenance, and parking, they would also incur expenses in the form of transit fares. With a marginal vehicle operating cost of about $0.20 per mile and a round trip of 80 miles, the vehicle cost savings would be $16, which compares with expected fares of around

$20 to $24 round-trip (based on current MBTA Zone 8-10 fares). Parking cost savings would be accrued by some, not all, commuters, as some employers provide free parking. Cost savings for other highway travelers also could not be estimated since the impacts of the project on highway congestion have not been modeled.

Benefits of the bus alternatives were not estimated, as these alternatives would involve minimal capital investment, and the Study team's professional experience, the literature, and stakeholder interviews suggested that associated development impacts would also be minimal.

4.1.2 Methodology

IMPLAN is a regional input-output model used to measure how changes in economic activity lead to direct, indirect, and induced changes in output, final payments, employment, and final demand. This analysis used the IMPLAN model version 3.1.1001.12, released in 2013. The study area for this analysis included the State of New Hampshire.

Construction Costs

This analysis was based on the projected external (primarily federal) capital spending in New Hampshire for the three rail alternatives: Commuter Rail with terminals in Nashua and Manchester and Intercity 8 rail with a terminal in Concord. Internal spending (i.e., funding from New Hampshire sources) is not included, as there will be an impact of reduced consumer spending that will offset the construction spending benefit.

The source for this spending is the list of line items produced by Jacobs Engineering Inc. for NHDOT in September, 2014. The approach was as follows:

- Isolate the line items that are located within the State of New Hampshire
- Identify the alternatives for which each line item is relevant
- Assign the line items IMPLAN industry codes
- Compute total spending by alternative and industry
- Factor the spending to compute the projected external share
- Divide the external share among the construction years 2019-2022

The Capitol Corridor project includes approximately 10 miles of track improvements and stations in Massachusetts; the Nashua alternative does not include any revenue track or stations in New Hampshire (though it does include service track and a layover yard there). Project costs were divided by state based on information provided by Jacobs on the locations of the costs incurred.

IMPLAN uses a unique system of industry codes that differs from other classification systems. When modeling the economic impact of a project, the inputs to IMPLAN consist of the projected productivity of each industry, equivalent in this case to the income earned by each sector from out-of-state sources. Capital spending was assigned to the four IMPLAN industries in Table 4.1.

Table 4.1: IMPLAN Industries Associated with Capital Spending

IMPLAN Number	IMPLAN Name	Description
36	Construction of other new non-residential structures	Proxy for all new construction spending on track and facilities
39	Maintenance and repair construction of non-residential structures	Proxy for "maintenance and protection" spending on track and facilities
360	Real estate establishments	Proxy for land acquisition
369	Architectural, engineering, and related services	Includes "final design and construction phase services" for each alternative

A formal financing plan has not yet been finalized and the project has not yet been submitted for federal funding. Consequently, professional judgment was used to estimate that less than half the project costs will be covered by NHDOT, with the remainder coming from external sources, including the Federal Transportation Administration (FTA). To reflect these projections, the cost of each of the alternatives was factored to account for those external sources of capital funding. Project construction is projected to occur between 2019 and 2022.

Residential Relocation and Business Expansion

The development estimates provided in Section 2.0 were used as a basis for estimating the long-term change in jobs and output related to residential and business growth. It is assumed that the new growth identified in Section 2.0 will all occur by the year 2030. Benefits will also accrue in earlier years in proportion to the amount of development realized by that year. It is further assumed that this is new development in the Southern New Hampshire region, rather than a relocation of activity that would have occurred anyway within the region.

The following impacts related to new development were included:

- Real estate construction and sales – Commercial valued at $95.49 per square foot[19] and residential valued at $167,000 to $181,000 per unit.[20] These benefits are assumed to accrue over a 10-year period (2021–2030).
- Earnings of new resident workers (based on the average income for New Hampshire), which are reinvested in the New Hampshire economy. These will be ongoing, annual benefits reaching their full extent in 2030 and beyond.

[19] http://www.loopnet.com/Nashua_New-Hampshire_Market-Trends
[20] Derived from Trulia listings, adjusted for an eight percent premium for proximity to commuter rail

4.1.3 Results

Table 4.2 shows the estimated impact on jobs for each alternative by year. These results include direct jobs in project construction and real estate development, as well as indirect and induced jobs related to spending flowing through the economy. Over the four-year construction period, the various alternatives are projected to generate between 80 and 350 new jobs.[21] Impacts are largest for the Intercity 8 alternative to Concord, since this alternative would include the longest track improvements and most stations. Real estate development between 2021 and 2030 is projected to generate between 850 and 3,390 new jobs. The reinvested earnings of new residents are expected to generate between 380 and 1,730 new jobs per year in 2030 and beyond, with proportionally smaller benefits increasing from 2021 to 2029 as development scales up. The greatest real estate and earnings impacts are for the Manchester Regional Commuter Rail alternative since this alternative is expected to have the largest development impacts.

Table 4.2: Impacts on Employment (Jobs) by Alternative

Alternative	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	230	3,390	1,730
Nashua Minimum Commuter Rail	80	850	380
Intercity 8	350	2,460	1,140

Table 4.3 shows the estimated impact on output (gross regional product, or GRP) for each alternative by year. Over the four-year construction period, the various alternatives are projected to generate between $20 and $100 million in new state output. Real estate development between 2021 and 2030 is projected to generate between $260 million and $1.2 billion in new state output, cumulatively over this period. The reinvested earnings of new residents are expected to generate between $50 million and $220 million in new state output, in 2030 and beyond, with proportionally smaller benefits increasing from 2021 to 2029 as development scales up. The impacts by alternative are similar to the job impacts, with the Intercity 8 to Concord generating the largest construction impacts and the Manchester Regional Commuter Rail generating the largest real estate and earnings benefits.

Table 4.3: Impacts on Output (Gross Regional Product) by Alternative (In Millions, 2014$)

Alternative	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	$70	$1,200	$220
Nashua Minimum Commuter Rail	$20	$260	$50
Intercity 8	$100	$750	$140

[21] A new "job" is really a "job-year", i.e., 353 jobs over a four-year period is equivalent to 88 jobs that each continue for the entire four-year period

IMPLAN also reports changes in federal, state, and local tax receipts. These include revenue from taxes on employee compensation (social insurance), production and imports (sales, property, motor vehicle, and other taxes), households (income, property, and licenses, fines and fees), and corporations (profits and dividends). The net changes are shown in Table 4.4. The vast majority of new tax receipts are from taxes on production and imports and corporations.

Table 4.4: Impacts on State and Local Tax Receipts by Alternative (In Millions, 2014$)

Alternative	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Manchester Regional Commuter Rail	$1.3	$43.3	$13.1
Nashua Minimum Commuter Rail	$0.5	$9.3	$2.9
Intercity 8	$2.1	$27.1	$8.7
Intercity Bus	0	0	0
No Build	0	0	0

4.2 Comparison of Economic Benefits, Costs, and Revenues

The Study team integrated the forecast stream of economic benefits with the forecast streams of costs and revenues to derive a timeline of costs, revenues, and economic benefits forecast to result from a state investment in the Manchester Regional Commuter Rail alternative. Table 4.5 shows a 35-year time horizon with forecast annual costs, cash receipts, and public benefits for each future year. **All costs, revenues, and benefits are shown in 2014 dollars.**

Table 4.5: Forecast Annual Costs, Revenues, and Economic Benefits (In Millions, 2014$)

Year	Total Financial Costs	Total Cash Receipts	Passenger Revenue	Federal 5307 Funding	Incremental Gross Regional Product
Present Value	$537	$326	$261	$64	$6,176
2015	$2.0	$0.0	$0.0	$0.0	$0.0
2016	$2.0	$0.0	$0.0	$0.0	$0.0
2017	$2.0	$0.0	$0.0	$0.0	$0.0
2018	$2.0	$0.0	$0.0	$0.0	$0.0
2019	$9.4	$0.0	$0.0	$0.0	$17.5
2020	$8.5	$0.0	$0.0	$0.0	$17.5
2021	$7.6	$0.0	$0.0	$0.0	$39.5
2022	$6.7	$0.0	$0.0	$0.0	$83.5
2023	$16.5	$7.1	$7.1	$0.0	$66.0
2024	$16.6	$7.2	$7.2	$0.0	$88.0
2025	$16.8	$9.8	$7.4	$2.5	$110.0
2026	$16.9	$10.0	$7.5	$2.5	$132.0
2027	$17.0	$10.1	$7.7	$2.5	$154.0
2028	$17.1	$10.3	$7.8	$2.5	$176.0
2029	$17.2	$10.5	$8.0	$2.5	$198.0
2030	$17.3	$10.6	$8.1	$2.5	$220.0
2031	$17.4	$10.8	$8.3	$2.5	$222.2
2032	$17.5	$10.9	$8.5	$2.5	$224.4
2033	$20.6	$11.1	$8.6	$2.5	$226.7
2034	$20.8	$11.3	$8.8	$2.5	$228.9
2035	$20.9	$11.5	$9.0	$2.5	$231.2
2036	$21.0	$11.6	$9.2	$2.5	$233.5
2037	$21.1	$11.8	$9.3	$2.5	$235.9
2038	$21.3	$12.0	$9.5	$2.5	$238.2
2039	$21.4	$12.2	$9.7	$2.5	$240.6
2040	$15.8	$12.4	$9.9	$2.5	$243.0
2041	$15.9	$12.6	$10.1	$2.5	$245.4
2042	$16.0	$12.8	$10.3	$2.5	$247.9
2043	$16.2	$13.0	$10.5	$2.5	$250.4
2044	$16.3	$13.2	$10.7	$2.5	$252.9
2045	$16.4	$13.4	$10.9	$2.5	$255.4
2046	$16.6	$13.6	$11.2	$2.5	$258.0
2047	$16.7	$13.9	$11.4	$2.5	$260.5
2048	$16.8	$14.1	$11.6	$2.5	$263.2
2049	$17.0	$14.3	$11.8	$2.5	$265.8
2050	$17.1	$14.6	$12.1	$2.5	$268.4

Total Financial Costs:

- Engineering and design at $2 million per year over four years
- Debt service on long-term bonds for 20 years, plus the interest on Grant Anticipation Notes during the four-year construction period
- O&M costs starting once construction is complete and escalating at one percent per year as ridership grows
- Capital renewal allowance for periodic rail and tie renewal as well as other periodic asset refurbishment costs

Total Cash Receipts:

- Passenger revenue once service starts
- Federal formula funding based on route miles and vehicle miles of operation

Future passenger revenue grows at a conservative long-term rate of two percent per year as development occurs to stimulate ridership growth.

Incremental Gross Regional Product includes benefits of employee wages, business earnings, and state and local tax receipts associated with project construction, real estate development, and ongoing increased economic activity in the state. Projecting beyond 2030, this is assumed to grow at two percent per year as ridership grows.

With an allowance for capital renewal, the forecast cash receipts (fare revenue and federal formula funds) over the next 35 years approach, but do not fully cover, the annual financial costs for engineering, debt retirement, operating costs, and asset renewal. However, forecast economic benefits in terms of employee wages, business earnings, and tax receipts clearly exceed the annual financial costs of the service.

While the forecast economic benefits are estimates, if only half that forecast growth in regional economic activity is achieved, the benefits would still outweigh the net financial liabilities by a large margin.

1 Introduction

1.1 Purpose of Report

This Sustainable Land Use Technical Report was prepared in support of Task 7 of the New Hampshire Capitol Corridor Rail & Transit Alternative Analysis (AA) Study. The objective of this report is to evaluate the sustainability of the potential land use impacts of the project in the Study corridor.

1.2 Methodology

The approach for preparing this report included the following tasks:

- Defining the scope of analysis
- Reviewing station locations for the seven intermediate alternatives
- Reviewing station area land use and economic development characteristics
- Evaluating final alternatives against the defined goals

2 Sustainable Land Use Goals

As stated in the Purpose and Need document (Appendix 2 to the Capitol Corridor AA Final Report), a sustainable transportation system is one that meets and balances the existing environmental, social, and economic needs of a community without compromising resources for future generations. Each transit investment alternative was evaluated for its ability to meet land use goals in these three categories.

- Environmental Goals:
    - Catalyze more compact, infill transit-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power) to support new development, and supporting maintenance of existing open/rural space
    - Reduce reliance on cars for trips/errands
- Social Goals:
    - Expand mobility and transportation choice for all ages
    - Support low-income households through increased access to jobs
- Economic Goals:
    - Attract employers to New Hampshire
    - Attract and retain regional employers to New Hampshire and Boston
    - Provide improved residency location choice in New Hampshire for commuters to Boston or regional jobs

2.1 Environmental Goals

The following situations describe the degree to which the transit investment may meet the defined environmental goals.

Sub goal 1: Catalyze more compact, infill transit-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power) to support new development, and supporting maintenance of existing open/rural space.

Transit investments have shown ability to catalyze or influence a Transit-Supportive Development (TSD) or Transit-Oriented Development (TOD) around station areas. Four pre-conditions are necessary for this to occur:

- Favorable real estate market conditions
- Available land for development
- Transit-supportive land use policies and plans (comprehensive plans, neighborhood plans, zoning ordinances, parking policy, etc.)
- Urban design that supports efficient and pleasant station access

These four conditions are generally mode/service-neutral. Variations in the ability to support this sub goal come from the differing degrees to which various modes and service schedules influence TSD/TOD. Fixed guideway modes (heavy rail, light rail, commuter rail, and streetcar) historically have tended to have more significant impact on development than flexible modes (express bus, standard bus, vanpool, bikeshare, etc.). Service that is more frequent and faster also tends to have a more significant impact than service that is infrequent (e.g., peak hour only, or long head-ways) or offers slower trips (e.g., all-stops vs. express or skip-stop).

By concentrating more development in existing areas (infill) around stations, not in outlying greenfield areas, transit service can reduce the need for additional infrastructure investments at the urban edge.

Likewise, as increased choice in places to live, work, and visit become available through the development of TSD/TOD, demand for development at the urban fringe that can consume agricultural land and place pressure on previously undeveloped open spaces may be reduced. The conveniences of locating closer to transit stations may come to outweigh the benefits of edge/semi-rural living for some households or businesses, increasing demand for space in existing urban areas or new infill development.

Therefore, the following can be concluded:

- Rail alternatives will meet this goal better than bus alternatives
- Alternatives with more runs/trips will meet this goal better than alternatives with fewer trips

Sub goal 2: Reduce reliance on cars for trips/errands.

Increased transit service indicates increased choice in how people travel for work, shopping, entertainment/recreation, and other purposes. Some households may choose to use transit for their trips instead of cars, which may reduce Vehicle Miles Travelled (VMT) by single-occupancy vehicles. Overall reductions in VMT reduce roadway congestion and emissions produced by passenger automobiles. The degree to which overall mode share shifts between single-occupancy passenger automobile based trips and transit, and changes in the absolute numbers of vehicle-based trips is complex and depends upon a number of circumstances:

- Travel patterns for various types of trips: local vs. regional, single-destination vs. chained trips, work vs. non-work
- Service frequency
- Station location and proximity to desired destinations
- Population and employment growth in station areas and across the service area
- Other exogenous factors, such as fuel costs

Mode-shift and VMT changes and related emissions reductions were not modeled for this Study. However, the following can be concluded:

- Alternatives that offer additional runs or trips will support this goal, with alternatives offering more frequent service coverage meeting the goal comparatively better
- Alternatives that introduce new station locations or transit access points will also meet this goal comparatively better than alternatives that use the same alignment and station locations as existing conditions

2.2 Social Goals

The following situations describe the degree to which the transit investment may meet the defined social goals.

Sub goal 1: Expand mobility and transportation choice for all ages.

Compared to the existing transit service, alternatives that introduce more opportunities for people to move efficiently from place-to-place increase mobility. This can result from increased options for routes, increased windows for travel time, and new modes or means for travel (transportation choice). Therefore, the following can be concluded:

- Alternatives that offer additional runs or trips will support this goal, with alternatives offering more frequent service coverage meeting the goal comparatively better
- Alternatives that introduce new station locations or transit access points (as destinations and as intermediate stops) will also meet this goal comparatively better than alternatives that use the same alignment and station locations as the baseline

Sub goal 2: Support low-income households through increased access to jobs.

Alternatives that introduce new connections – origins and/or destinations – or make it easier to get from place-to-place increase access. Connections to employment centers will result in increased access to jobs. Therefore, the following can be concluded:

- Alternatives that introduce new station locations or transit access points (as destinations and as intermediate stops) will meet the "increased access to jobs" component of this goal comparatively better than alternatives that use the existing alignments/routes and station locations as the baseline (assuming that one or more of the station locations [new or existing] feature employment uses within walking or connecting distance of the station)
- New station/stop locations that are located within areas that have a presence of low-income households, or that have connections (via feeder bus, pedestrian or non-motorized paths, or roadways) to areas with a presence of low-income households will meet the "supports low-income households" component of this goal comparatively better than alternatives that feature station locations in areas where household incomes meet or exceed area median incomes

2.3 Economic Goals

The following situations describe the degree to which the transit investment may meet the defined economic goals. As discussed in the *Social Goals* section above, alternatives that create more opportunities for people to move efficiently from place-to-place and open up more connections to transportation serve to increase access and mobility. Access and mobility also affect the economies of the places served by transportation, at local and regional levels.

Sub goal 1: Attract employers locally to New Hampshire, and attract and retain regional employers from New Hampshire to Boston.

Employers in most industry sectors consider a variety of labor force characteristics when choosing locations for their business concerns. These may include typical levels of educational attainment and availability of specialized skills required by their business processes, but also consider to some degree how easy it will be for employees to get to work or to conduct any intra-workday travel that may be required. Good access and high degrees of resident mobility correspond to workforce stability, on-time performance, and lower levels of turnover related directly to employees' ability to get to work consistently and on time.

From the perspective of current or prospective employees, the transportation infrastructure that provides access to a job site also affects the decision to take a job with that company, whether the employer contributes financially to its construction and operation or not. Other factors being equal, employees may choose a job that is easier to get to, or for which they have multiple choices in how to get to, over another similar job that is less accessible. In this way, employers may also present transportation access as a job benefit and way to attract and retain quality employees.

Therefore, the following can be concluded:

- Alternatives that offer increased access and mobility will support this goal, with alternatives offering more frequent service and/or new station locations or transit access points meeting this goal comparatively better than alternatives that use the same alignment and station locations as the baseline
- Alternatives that provide more reliable service (i.e., rail-based or in dedicated right-of-way) will meet this goal comparatively better than alternatives that simply provide more service

Sub goal 2: Provide improved residency location choice in New Hampshire for commuters to Boston or regional jobs.

For many households, the decision on where to live may include preferences for a certain style or price-point of housing stock, neighborhood, or community, and proximity to shopping, healthcare, and open and space/recreation (among other types of destinations). Other factors may include proximity to extended family, or ties to an area where household members grew up or previously lived. For many, access to employment is also important: choice and convenience in ways to get to work, travel time length and consistency, and impacts of the commute on quality-of-life. Transportation investments that increase access across a region and increase the number of potential connections between residential centers and employment centers provide more choice to employees as to where they can live according to their preferences (e.g., a rural New Hampshire hamlet with a short drive to a transit station) and still work in the region (e.g., Boston's financial district).

Multiple choices will help retain skilled employees and productive citizens in the region, because they are not obligated to move away from their preferred residence location to access jobs. Communities may have an additional desire to maintain the balanced age distribution necessary for healthy communities, and retaining workers in all age groups accomplishes that policy goal. (For example, young professional workers from New Hampshire who work in Boston are less likely to move to Massachusetts to work in their industry of choice.)

Therefore, the following can be concluded:

- Alternatives that offer increased access will support this goal, with alternatives offering more new station locations or transit access points meeting this goal comparatively better than alternatives that use the same alignment and station locations as the baseline

3 Review of Station Characteristics

3.1 Summary of Final Alternatives

This section describes the baseline, three bus, two commuter rail, and one intercity rail investment options that advanced through preliminary screening leading towards the selection of recommended strategies (see Tables 3.1 and 3.2). Details concerning each final investment option are listed below with more detail available in the Task 7 Technical Report, Detailed Evaluation of Alternatives (Appendix 7 to the AA Final Report).

Table 3.1: Summary of Alternatives

Base	▪ No investment; existing bus and rail services are continued, but not expanded
Expanded Base	▪ New Hampshire's Boston Express (BX) bus service is increased from current 80 buses per day to 120 buses per day ▪ All peak buses run direct and non-stop between each NH park-and-ride lot and Boston South Station with service every 30 minutes ▪ Each park-and-ride lot sees hourly off-peak service making intermediate stops at each NH park-and-ride lot ▪ No changes to existing passenger rail services
Bus on Shoulder	▪ BX bus service of 80 daily trips is permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes ▪ Savings of eight to 12 minutes predicted during the morning peak period ▪ No significant travel time savings predicted during the afternoon peak period
Expanded Bus on Shoulder	▪ 120 daily trips permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes ▪ Savings of eight to 12 minutes predicted during the morning peak period ▪ No significant travel time savings predicted during the afternoon peak period
Manchester Regional Commuter Rail	▪ Extends Massachusetts Bay Transportation Authority (MBTA) commuter rail service north from Lowell, MA to Manchester, NH with intermediate stops at South Nashua, Nashua Crown St., and Bedford/Manchester-Boston Regional Airport (Bedford/MHT) ▪ BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained ▪ BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained
Nashua Minimum Commuter Rail	▪ Extends MBTA commuter service north from Lowell, MA to South Nashua, NH ▪ BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained ▪ BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained
Intercity 8	▪ Four daily intercity passenger rail round trips between Concord, NH and Boston, MA making intermediate stops at Manchester, Bedford/MHT, Nashua Crown St., and Lowell and Woburn, MA ▪ Base BX service is retained

3.2 Summary of Land Use and Economic Development Conditions

A detailed analysis of the land use and economic development characteristics of proposed transit stations is contained in the technical memorandum *Land Use & Economic Development Analysis* dated January 2014 and in the draft supporting working memorandum *Land Use Evaluation of Alternatives for Preliminary Screening* dated September 2013. The findings from those memoranda are not repeated here, but are incorporated by reference.

4 Analysis Presented by Goal

This section of the report contains a qualitative assessment of each alternative's anticipated potential to meet the three sustainable land use goals. This qualitative assessment is based upon an understanding of service levels and route characteristics of the alternatives, as well as the varied land use and socio-economic characteristics of each of the station areas served by the alternative.

A station-level assessment is provided for each station area served by an alternative, with footnotes explaining the rationale for assessment. Assessments were absolute, not relative rankings among alternatives. Ratings are provided on the following scale:

- N/A: For the alternative, there is no service to this station
- No Change: This alternative is not anticipated to have any effect on this aspect of sustainable land use
- Negative: This alternative could potentially reduce sustainability
- Low: This alternative is anticipated to have some positive effect on this aspect of sustainable land use
- Medium: This alternative is anticipated to have a solidly positive effect on this aspect of sustainable land use
- High: This alternative is anticipated to have a very positive effect on this aspect of sustainable land use

These very localized assessments were then rolled-up as a composite assessment for the overall alternative. A summary of the composite goals is presented in Section 5.0.

4.1 Environmental Goals

Environmental Goals:

1. Catalyze more compact, infill transit-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power) to support new development, and supporting maintenance of existing open/rural space
2. Reduce reliance on cars for trips/errands

Assessments for the Environmental Goals are presented in Tables 4.1 and 4.2. Each sub-goal was assessed separately due to different influencing factors.

Table 4.1: Evaluation of Environmental Goals by Alternative and Station

Location	Rail Station (Proposed)	Bus Station (Existing)	Alternative						
			Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Number of Stations (excluding existing MA + Boston terminal)			7 Bus	7 Bus	7 Bus	7 Bus	4 Rail 5 Bus	1 Rail 4 Bus	4 Rail 8 Bus
Composite/Environmental Goals			**no change**	**low**	**low**	**low**	**medium**	**low**	**low/ medium**
Composite/Environmental Sub-Goal 1: catalyze more compact, infill transit supportive land use and development patterns			**no change**	**low/no change**	**low/no change**	**low/no change**	**low/ medium**	**low**	**low**
Concord, NH	X	X	no change	n/a	n/a	n/a	n/a	n/a	low [3]
Manchester, NH: Granite Street	X	X	no change	low/no change	low/no change [2]	low/no change [2]	medium [4]	low/no change [1,2]	medium [4]
Bedford/MHT	X		n/a	n/a	n/a	n/a	low/no change [6]	n/a	low/no change [6]
N. Londonderry, NH: Exit 5		X	no change	low/no change [1]	low/no change [2]	low/no change [2]	low/no change	low/no change [1,2]	no change [1,2]
Londonderry, NH: Exit 4		X	no change	low/no change [1]	low/no change [2]	low/no change [2]	low/no change	low/no change [1,2]	no change [1,2]
Nashua, NH: Exit 8		X	no change	low/no change [1]	low/no change [2]	low/no change [2]	no change/ negative [5]	no change/ negative [5]	no change [1,2]
Nashua, NH: Crown Street	X		n/a	n/a	n/a	n/a	low/medium [3,4]	n/a	low/ medium [3,4]
South Nashua, NH: Spit Brook Road or Pheasant Lane Mall	X		n/a	n/a	n/a	n/a	low [3]	low [3]	n/a
Tyngsborough, MA: Exit 36		X	no change	low/no change [1]	low/no change [2]	low/no change [2]	n/a	n/a	n/a
Salem, NH: Exit 2		X	no change	low/no change [1]	low/no change [2]	low/no change [2]	low/no change [1]	low/no change [1]	no change [1,2]

[1] Traditional bus service was not correlated to changing or encouraging more transit-oriented land use and development patterns, particularly in systems with highway service and park-and-ride commuter stations
[2] Bus on shoulder was not correlated to changing or encouraging more transit-oriented land use and development patterns, particularly in systems with highway service and park-and-ride commuter stations
[3] Proposed station location, local real estate conditions, accessibility and urban design, and service schedule suggest some positive potential for transit-oriented development
[4] Proposed station location, local real estate conditions, accessibility and urban design, and service schedule suggest positive potential for TOD
[5] Elimination of bus service may reduce or eliminate the marginal correlations of bus service to TOD patterns
[6] Proposed station location, local real estate conditions, accessibility and urban design, function as a park-and-ride, and service schedule suggest little potential for TOD

Table 4.2: Evaluation of Environmental Goals by Alternative and Station

Location	Rail Station (Proposed)	Bus Station (Existing)	Alternative						
			Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Number of Stations (excluding existing MA + Boston terminal)			7 Bus	7 Bus	7 Bus	7 Bus	4 Rail 5 Bus	1 Rail 4 Bus	4 Rail 8 Bus
Composite/Environmental Sub-Goal 2: reduce reliance on cars for trips/errands			**no change**	**medium**	**low**	**medium**	**medium**	**low/ medium**	**medium**
Concord, NH	X	X	no change	n/a	n/a	n/a	n/a	n/a	medium [7]
Manchester, NH: Granite Street	X	X	no change	medium [7]	low [8]	medium [8]	high [7,8]	low/no change [7,8]	medium [7]
Bedford/MHT	X		n/a	n/a	n/a	n/a	low [7]	n/a	medium [7]
N. Londonderry, NH: Exit 5		X	no change	medium [7]	low [8]	medium [8]	low/no change [7]	low/no change [7,8]	no change [7,8]
Londonderry, NH: Exit 4		X	no change	medium [7]	low [8]	medium [8]	low/no change [7]	low/no change [7,8]	no change [7,8]
Nashua, NH: Exit 8		X	no change	medium [7]	low [8]	medium [8]	no change/ negative [9]	no change/ negative [9]	no change [7,8]
Nashua, NH: Crown Street	X		n/a	n/a	n/a	n/a	high [7,8]	n/a	medium [7]
South Nashua, NH: Spit Brook Road or Pheasant Lane Mall	X		n/a	n/a	n/a	n/a	high [7,8]	high [7]	n/a
Tyngsborough, MA: Exit 36		X	no change	medium [7]	low [8]	medium [8]	n/a	n/a	n/a
Salem, NH: Exit 2		X	no change	medium [7]	low [8]	medium [8]	low/no change [7]	low/no change [7]	no change [7,8]

[7] Increased service may provide more choice for use in some trips, but only between stations, as this is commuter service, not local service
[8] Increased travel speed may provide more choice for use in some trips, but only between stations, as this is commuter service, not local service
[9] Elimination of bus service may reduce or eliminate choice for some trips

4.2 Social Goals

Social Goals:

- Expand mobility and transportation choice for all ages
- Support low-income households through increased access to jobs

Assessments for the Social Goals are presented in Tables 4.3. The two sub-goals have been assessed together due to the same influencing factors.

Table 4.3: Evaluation of Social Goals by Alternative and Station

Location	Rail Station (Proposed)	Bus Station (Existing)	Stations Served by Alternative						
			Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Number of Stations (excluding existing MA + Boston terminal)			7 Bus	7 Bus	7 Bus	7 Bus	4 Rail 5 Bus	1 Rail 4 Bus	4 Rail 8 Bus
Composite Assessment/Social Goals			**no change**	**low**	**low**	**low**	**low/medium**	**low**	**low/ medium**
Concord, NH	X	X	no change	n/a	n/a	n/a	n/a	n/a	medium [10]
Manchester, NH: Granite Street	X	X	no change	low [10]	low [10]	low [10]	medium [10]	low/no change [10]	medium [10]
Bedford/MHT	X		n/a	n/a	n/a	n/a	medium [10]	n/a	medium [10]
N. Londonderry, NH: Exit 5		X	no change	low [10]	low [10]	low [10]	low/no change [10]	low/no change [10]	low/no change [10]
Londonderry, NH: Exit 4		X	no change	low [10]	low [10]	low [10]	low/no change [10]	low/no change [10]	low/no change [10]
Nashua, NH: Exit 8		X	no change	low [10]	low [10]	low [10]	no change/ negative [11]	no change/ negative [11]	no change [10]
Nashua, NH: Crown Street	X		n/a	n/a	n/a	n/a	medium [10]	n/a	medium [10]
South Nashua, NH: Spit Brook Road or Pheasant Lane Mall	X		n/a	n/a	n/a	n/a	medium [10]	medium [10]	n/a
Tyngsborough, MA: Exit 36		X	no change	low [10]	low [10]	low [10]	n/a	n/a	n/a
Salem, NH: Exit 2		X	no change	low [10]	low [10]	low [10]	low/no change [10]	low/no change [10]	no change [10]

[10] *Increased service or new station will provide more choice for use in some trips, increasing access and mobility*
[11] *Elimination of bus service may reduce or eliminate choice for some trips, reducing access and mobility*

4.3 Economic Goals

Economic Goals:

- Attract employers locally to New Hampshire
- Attract and retains regional employers from New Hampshire to Boston
- Provide improved residency location choice in New Hampshire for commuters to Boston or regional jobs

Assessments for the Economic Goals are presented in Tables 4.4. The three sub-goals have been assessed together due to the same influencing factors.

Table 4.4: Evaluation of Economic Goals by Alternative and Station

Location	Rail Station (Proposed)	Bus Station (Existing)	Stations served by Alternative						
			Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Number of Stations (excluding existing MA + Boston terminal)			7 Bus	7 Bus	7 Bus	7 Bus	4 Rail 5 Bus	1 Rail 4 Bus	4 Rail 8 Bus
Composite Assessment/Economic Goals			**no change**	**medium**	**low**	**medium**	**medium**	**low**	**medium**
Concord, NH	X	X	no change	n/a	n/a	n/a	n/a	n/a	medium [12, 13]
Manchester, NH: Granite Street	X	X	no change	medium [13]	low [13]	medium [13]	medium [12, 13]	medium [12, 13]	medium [12, 13]
Bedford/MHT	X		n/a	n/a	n/a	n/a	medium [12]	n/a	medium [12]
N. Londonderry, NH: Exit 5		X	no change	medium [13]	low [13]	medium [13]	low/no change [13]	low/no change [13]	low/no change [13]
Londonderry, NH: Exit 4		X	no change	medium [133]	low [13]	medium [13]	low/no change [13]	low/no change [13]	low/no change [13]
Nashua, NH: Exit 8		X	no change	medium [13]	low [13]	medium [13]	no change/ negative [13,14]	no change/ negative [13,14]	low/no change [13]
Nashua, NH: Crown Street	X		n/a	n/a	n/a	n/a	medium [12]	n/a	medium [12]
South Nashua, NH: Spit Brook Road or Pheasant Lane Mall	X		n/a	n/a	n/a	n/a	medium [12]	medium [12]	n/a
Tyngsborough, MA: Exit 36		X	no change	medium [13]	low [13]	medium [13]	n/a	n/a	n/a
Salem, NH: Exit 2		X	no change	medium [13]	low [13]	medium [13]	low/no change [13]	low/no change [13]	low/no change [13]

[12] New stations provide more options for local residents to commute within alignment or to Massachusetts/Boston destinations, expanding worker market
[13] Increased service or more reliable service can be perceived as employment market asset
[14] Elimination of some bus service may reduce or eliminate access for some workers to commuting options

5 Summary of Analysis

5.1 Summary Assessment of Goals by Alternative

Table 5.1 presents the composite assessments for each of the three categories of sustainable land use goals by alternative. The summary assessment is a roll-up of the composite assessments.

Table 5.1: Summary of Goals by Alternative

Environmental Goals	no change	low	low	low	medium	low	low/ medium
Social Goals	no change	low	low	low	low/ medium	low	low/ medium
Economic Goals	no change	medium	low	medium	medium	low	medium
Summary Assessment	**no change**	**low**	**low**	**low/ medium**	**medium**	**low**	**medium**

In summary, the three rail alternatives have higher qualitative assessments of contributing to sustainable land use than the bus alternatives or base scenario. As described in Section 2.0, rail investments have typically been perceived by the public (riders and community stakeholders) as more permanent and as providing greater levels-of-service and benefit than bus enhancements.

1 Introduction

Equitable access to transit investments – and the mobility benefits that these investments confer on riders – is an important consideration when assessing the alternatives developed through the Capitol Corridor Alternative Analysis (AA). Public transit investment supports broad improvements in mobility, but is a particularly critical tool in increasing the mobility of transit-reliant or -dependent populations, including households below the poverty line, minorities, and households in affordable housing units.

U.S. Census data was used to calculate statistics related to income, race, and housing for households and individuals in Census tracts within a half-mile of the Capitol Corridor alternatives (Pan Am Railways [PAR] right-of-way between the state lines of New Hampshire and Massachusetts and the potential rail station location in Concord, New Hampshire; Boston Express (BX) bus route between the state lines of New Hampshire and Massachusetts and the existing Manchester, New Hampshire BX station; and the Concord Coach bus route between the state lines of New Hampshire and Massachusetts and the existing Concord, New Hampshire Concord Coach station).

This data was also collected for the States of New Hampshire and Massachusetts, and the U.S. comparison between the alternatives within the larger geographic context will support the analysis of which alternatives minimize potential adverse impacts on concentrations of households below the poverty line, minority populations, and households in affordable housing units, while supporting equitable transit access by these populations.

2 Income and Poverty

Income is an important element of the equity analysis because the costs associated with car ownership are relatively fixed, and can consume a comparatively larger percentage of lower-income household budgets. Access to transit allows households to maintain mobility and access while reducing the household expenditures on transportation, which then increases the amount of discretionary budget available to the household.

Table 2.1 shows the median income of households in Census tracts within a half-mile of the Capitol Corridor alternatives, the States of New Hampshire and Massachusetts, and the U.S., as well as the percent of the population within a half-mile of the Capitol Corridor alternatives whose household income falls below the federal poverty line.

Table 2.1: Median Households Income and Percent of Population below the Poverty Line

	Median Household Income				% Below Poverty Line		
	2000	2000$ Adjusted for 2011	2011	% Change Adjusted for 2011 $	2000	2011	% Change
Capitol Corridor	--	--	$64,754	--	--	9.0%	--
New Hampshire	$49,467	$64,617	$64,664	0%	6.5%	8.0%	23%
Massachusetts	$50,502	$65,969	$65,981	0%	9.3%	10.7%	15%
U.S.	$41,994	$54,855	$52,762	-4%	12.4%	14.3%	15%

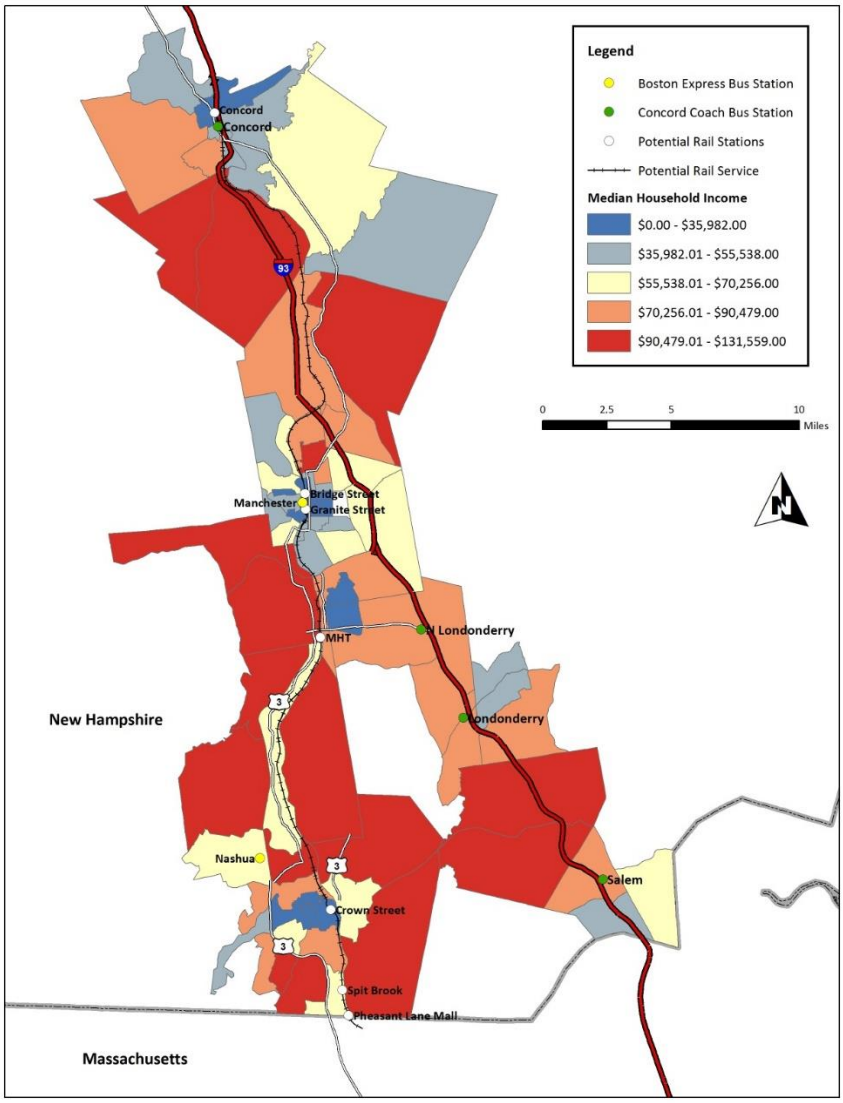
Source: U.S. Census 2000, ACS 2007-2011

The 2011 median household income of the Census tracts within a half-mile of the Capitol Corridor alternatives is approximately the same as the median household income for the State of New Hampshire. The 2011 percentage of the population below the poverty line is also lower in the Capitol Corridor than in Massachusetts or the U.S.

2.1 Median Household Income

While median household income within the Capitol Corridor is comparatively high, median household income declines in the urban areas, closer to where the potential rail stations would be located. Figure 2.1 shows Census tracts within a half-mile of all Capitol Corridor alternatives.

Figure 2.1: Median Income in Capitol Corridor by Census Tract



The median income in the cities of Concord, Manchester, and Nashua are all lower than the areas immediately surrounding each of these cities. Alternatives that have central-city station locations would expand the mobility options of the comparatively lower-income households that are concentrated in the urban areas. Service and operational improvements made to the BX service as part of the bus-based Capitol Corridor alternatives are unlikely to adversely impact comparatively lower-income households within the corridor; however, these alternatives are also unlikely to improve access to transit by this population because they will not result in the construction of new stations (and improved transit access) in areas with comparatively lower-income households.

2.2 Poverty

The percent of Capitol Corridor population living below the poverty line is consistent with or lower than state or national rates (Table 2.2).

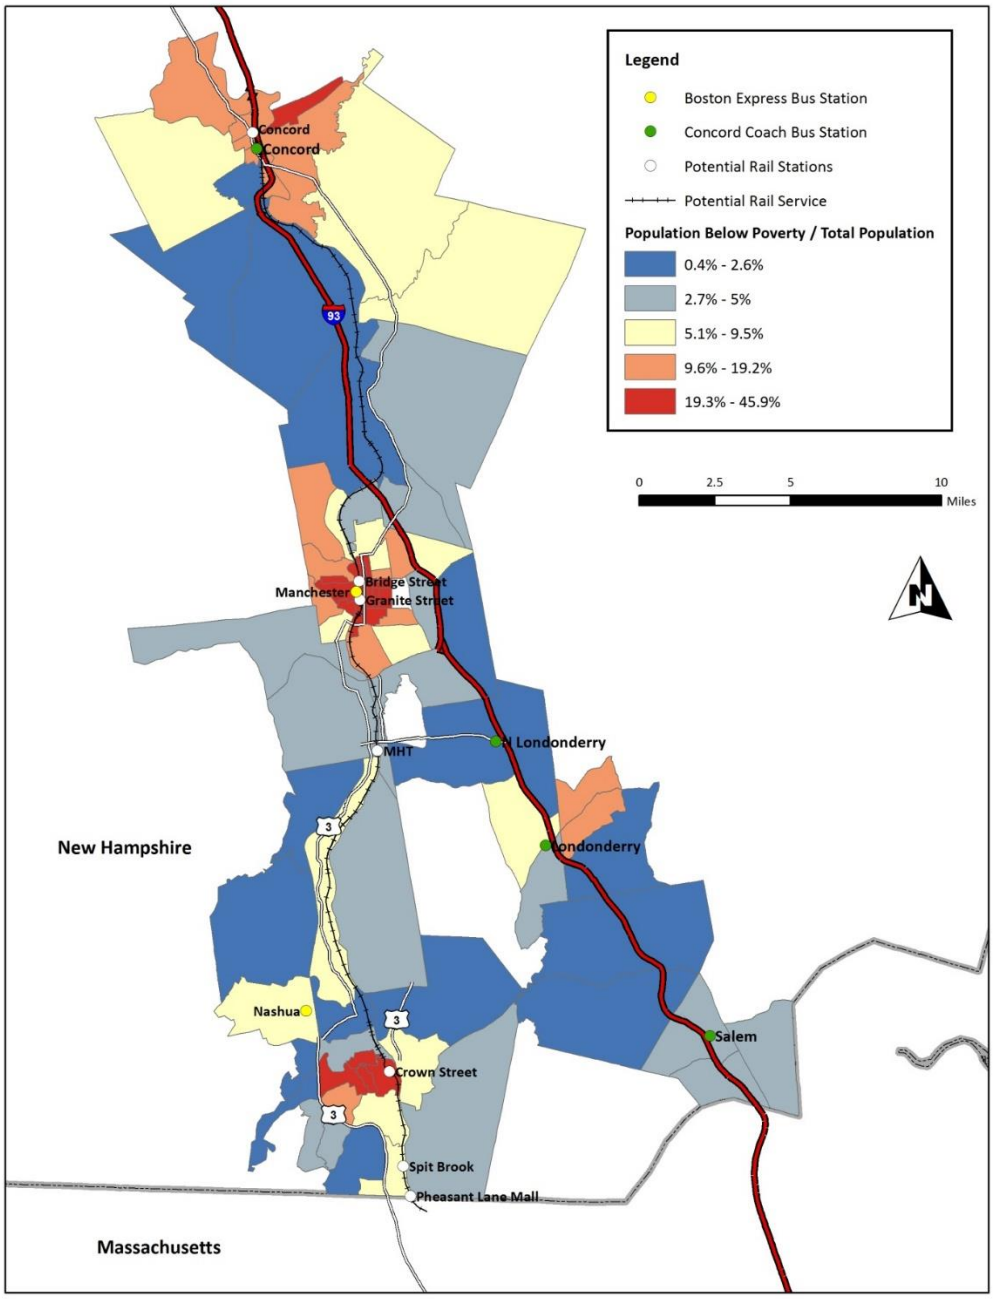
Table 2.2: Percent of Population Living below the Poverty Line

Geography	% Below Poverty Line
Capitol Corridor	9%
New Hampshire	8%
Massachusetts	11%
U.S.	14%

Source: U.S. Census, ACS 2008-2012

However, the poverty levels are comparatively higher in the central areas of Concord, Manchester, and Nashua. As Figure 2.2 shows, the poverty level in those downtowns ranges from 19 to 46 percent. Transit investments that directly serve these urban households living below the poverty line would promote equity through increased access to comparatively lower-cost transportation options. Service and operational improvements made to the BX service as part of the bus-based Capitol Corridor alternatives are unlikely to adversely impact people living below the poverty line within the corridor; however, these alternatives are also unlikely to improve access to transit by this population because they will not result in the construction of new stations (and improved transit access) in areas with comparatively large shares of the population living below the poverty line.

Figure 2.2: Percent of Population Living Below the Poverty Line



3 Minority Population

Approximately 10 percent of the population in Census tracts within a half-mile of the Capitol Corridor alternatives is non-white. Though this is higher than the minority population found within the State of New Hampshire (six percent), it is substantially lower than the percent of minority population found in the State of Massachusetts (19 percent) and the U.S. (26 percent), as shown in Table 3.1.

Table 3.1: Minority Population

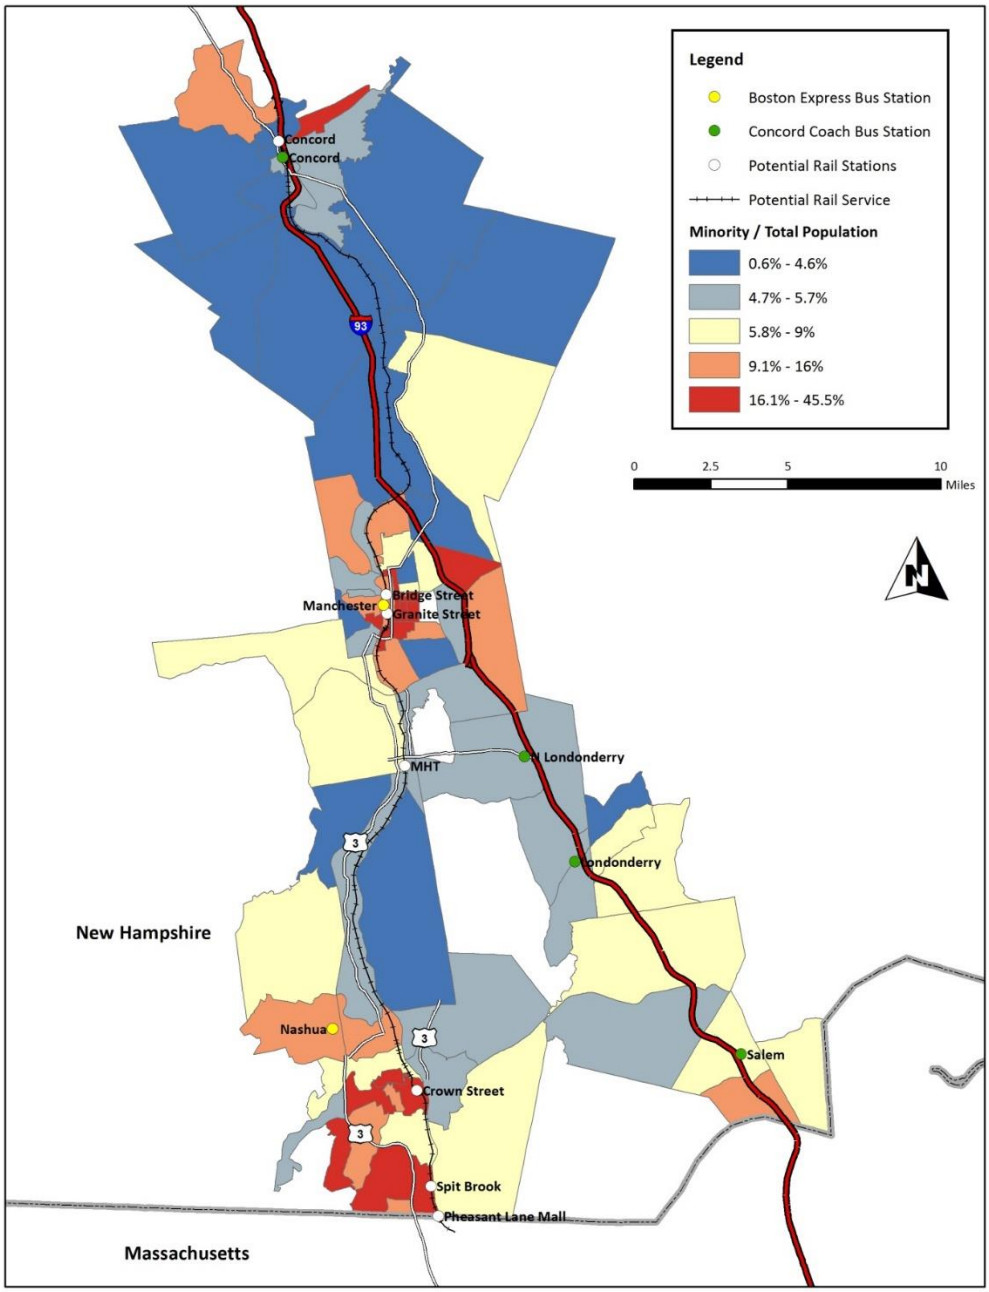
Geography	% Minority
Capitol Corridor	10%
New Hampshire	6%
Massachusetts	19%
U.S.	26%

Source: U.S. Census, ACS 2008-2012.

While the data shows that the share of minority population within the Capitol Corridor is comparatively lower than is found throughout Massachusetts and across the U.S., minority share of the population is comparatively higher in the central areas of Concord, Manchester, and Nashua. The minority population share in some parts of these cities reaches 45 percent. Figure 3.1 illustrates shares of minority population within the Capitol Corridor.

Alternatives that serve the downtown core of Concord, Manchester, and Nashua will serve the greatest shares of minority populations within the Capitol Corridor. Service and operational improvements made to the BX service as part of the bus-based Capitol Corridor alternatives are unlikely to adversely impact minority populations within the corridor; however, these alternatives are also unlikely to improve access to transit by this population because they will not result in the construction of new stations (and improved transit access) in areas with comparatively large shares of minority populations.

Figure 3.1: Minority Share of the Population



4 Affordable Housing

Many cities and states choose to develop voluntary or mandatory affordable housing statutes as a means to maintain an economically-diverse population and support diversity of housing choice.

New Hampshire has a Workforce Housing Law that went into effect on January 1, 2010. This law codifies and clarifies the 1991 New Hampshire Supreme Court decision in *Britton v. Town of Chester*, and requires all municipalities to provide reasonable and realistic opportunities for the development of workforce housing. It does not require that municipalities set aside a set percentage of its housing stock as affordable.

Here are some highlights of New Hampshire's Workforce Housing law:

- In every municipality that exercises the power to adopt land use ordinances and regulations, such ordinances and regulations must provide reasonable and realistic opportunities for the development of workforce housing, including rental multi-family housing. To provide such opportunities, lot size and overall density requirements for workforce housing must be reasonable. A municipality that adopts land use ordinances and regulations must allow workforce housing to be located in a majority, but not necessarily all, of the land area that is zoned to permit residential uses within the municipality.
- "Workforce housing" means housing that is intended for sale and that is affordable to a household with an income of no more than 100 percent of the median income for a four-person household for the metropolitan area or county in which the housing is located.
- "Workforce housing" also means rental housing that is affordable to a household with an income of no more than 60 percent of the median income for a three-person household for the metropolitan area or county in which the housing is located.
- Housing developments that exclude minor children from more than 20 percent of the units or in which more than 50 percent of the dwelling units have fewer than two bedrooms must not constitute workforce housing.

Concord, Manchester, and Nashua each have several affordable housing developments within a half-mile radius of the potential rail station locations. While the income of the households targeted for residence in these affordable housing units may not fall below the federal poverty line (as discussed in Section 2.0), additional comparatively lower-cost alternatives to car ownership (such as access to transit) can help to reduce the share of household income spent on transportation costs. Service and operational improvements made to the BX service as part of the bus-based Capitol Corridor alternatives are unlikely to adversely impact existing or planned affordable housing units; however, these alternatives are also unlikely to improve access to transit by this population because they will not result in the construction of new stations (and improved transit access) in areas with concentrations of affordable housing.

4.1 Concord

There are 11 affordable housing sites within a half-mile of the potential Concord rail station. Within the 11 sites, there are 398 affordable housing units (Figure 4.1 and Table 4.1).

Figure 4.1: Affordable Housing Sites in Concord

		Total Units	**398**

4.2 Manchester

There are 17 affordable housing sites within a half-mile radius of the proposed Granite Street Manchester rail stations. There are a total of 675 affordable housing units within these 17 sites (Figure 4.2 and Table 4.2).

Figure 4.2: Affordable Housing Sites in Manchester

5 Conclusion

The three populations considered as part of this equity analysis – population below the poverty line, minority populations, and households living in affordable housing units – tend to be concentrated in the central areas of Concord, Manchester, and Nashua. When compared to the base and bus alternatives, the rail alternatives offer comparatively higher levels of service and transit access to these populations with minimal adverse impacts anticipated. The equity of and access to the rail alternatives improves as transit service extends north from Nashua (to Manchester and/or Concord) because those alternatives (Manchester Regional Commuter Rail and Intercity 8), reach more individuals and households living below the poverty line, minority households, and households living in affordable housing units. The base and all bus alternatives would not adversely impact these populations either, but also would not offer expanded access to these populations through new station locations. Table 5.1 provides a summary of the equity metrics for each of the existing bus stations and proposed rail stations.

Table 5.1: Summary of Alternatives

Station Area (Half-Mile Buffer)	Proposed Rail Station	Existing Bus Station	Equity Metrics				Stations Served by Alternative(s)			
			Average Median Income	Population Below Poverty	Minority Population	Affordable Housing Units	Base and all Bus Alternatives	Intercity 8	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail

1 Final Estimates of Capital Cost

Refined capital cost estimates were prepared for more detailed final analysis of the two commuter rail, one intercity rail, and three bus options that advanced through preliminary screening. These are the Manchester Regional Commuter Rail, Nashua Minimum Commuter Rail, Intercity 8, Bus on Shoulder, Expanded Base, and Expanded Bus on Shoulder.

Rail Costs – The Study team revisited the infrastructure requirements for each of the three remaining rail options in meetings with Pan Am Railways (PAR), Massachusetts Department of Transportation (MassDOT), Massachusetts Bay Transportation Authority (MBTA), and New Hampshire Department of Transportation (NHDOT). The Study team was able to refine the preliminary infrastructure requirements based on their feedback and with the aid of two Hi-Rail trips along the corridor with railroad officials. The principal adjustments in the rail infrastructure upgrades necessary for the service include the following:

- Reappraisal and adjustment of passenger train schedules to restrict all meets between passenger trains to three locations:
    - Between Lowell (B25.4) and Tyngsborough Curve (B32.2)
    - Nashua Station (B37.4 to B38.7)
    - Manchester Station (B54.7 to B55.8)
- Reconsidered needs and limits of industrial freight sidings designed to avoid conflicts with passenger trains. Sidings required:
    - Nashua Corporation (B41.8 to B42.5)
    - Anheuser-Busch (B43.8 to B44.8)
    - Merrimack Running Track/Jones Chemical (B45.6 to B47.9)
    - Public Service of New Hampshire Receiving Track (B66.4 to B 68.5)
- Reappraisal of existing track conditions to reduce required track upgrades:
    - Replace only one-third of all ties due to better than anticipated tie conditions (50 percent had been assumed earlier)
    - Reduced rail weight standard from 132# to 112/115# rail due to recent PAR/Amtrak experiences
    - Retaining or relaying existing rail on tangent track and industrial sidings instead of replacing all rails to utilize all life left in existing rail and minimize initial required capital outlays. Relay and retained rail would need to be replaced in a multiyear program that would begin approximately 10 years after start of service.

PAR began supplying data on bridge conditions, track conditions, crossings, and other infrastructure in late March of 2014. Using this information together with field inspections of track, crossings, and

selected bridges, the Study team engineers were able to assemble more detailed evaluations of the conditions of existing assets. Study team engineers were able to estimate the costs of the various necessary upgrades using information from current and recent passenger rail development projects elsewhere in eastern Massachusetts together with inventory prices from the MBTA's commuter rail department. These cost categories are summarized below.

New and Rebuilt Track – Costs for labor and materials for new and rebuilt track were developed using track construction metrics, costs experienced on the MBTA's recent and current work improving its line to Fitchburg, and using current prices for materials in the MBTA/Massachusetts Bay Commuter Railroad (MBCR) inventory system. The length in miles of new and rebuilt track required for each service option is summarized in Table 1.1. Details showing where track would be replaced, rebuilt, and renewed are found in the conceptual track plans for commuter rail at the end of this report in Appendix A-1 and intercity rail in Appendix B-1. Cost parameters for new and rebuilt track are summarized in Table 1.2.

Table 1.1: Estimated Miles of New and Rebuilt Track by Type of Rail

	Replace Rail with Continuous Welded Rail (CWR)	Replace Rail with Relay Rail	New Track with CWR	New Track with Relay Rail

Track Switches – Needs for new and renewed switches in the track structure were identified as the track configuration was finalized for each option. Costs for new switches were derived using reported costs for installed switches on the MBTA's ongoing Fitchburg Line Improvement Project. Switch renewals were estimated at two-thirds of the installed cost for an entirely new switch. New and renewed switches for each of the three rail options are listed in Table 1.3.

Table 1.3: New and Renewed Switches by Service Option

Switch Location and Type	Installed Cost (2014$)	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8

Interlockings and Block Signals – The New Hampshire Main Line has a fully functioning Centralized Traffic Control (CTC) signal system in place between Lowell and CPN28 in Manchester that would be renewed and upgraded for the new passenger service. Existing block signals were identified by reference to PAR documentation. New and renewed interlockings were identified in the track configuration planning process. Estimated signal costs for new interlockings were based on average value for six new interlockings constructed on the nearby MBTA Fitchburg ML. Estimated costs to renew block signals were derived from the same source. Costs for interlocking renewal were estimated at two-thirds the cost of a new interlocking. See Table 1.4.

Table 1.4: New and Renewed Interlockings and Block Signals

Interlocking Location and Treatment	Installed Cost (2014$)	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Renew CPF-LO	$683,295	1	1	1

Automatic Highway Warning Devices (AHWD) – The rail line has 35 highway and pedestrian crossings between Lowell and Concord. The Study team inspected each crossing with an accompanying PAR signalman to determine its condition and identify necessary signal and warning system upgrades for each crossing. The site survey ran south to north to view the conditions at each of the 35 crossings from Wotton Street in Chelmsford, Massachusetts to Commercial Street in Manchester, New Hampshire. The specific cities and towns visited and the number of active crossings include Chelmsford (3), Tyngsborough (2), Nashua (6), Merrimack (4), Manchester (14), Hooksett (2), and Bow (4).

The Study team's estimate includes all material and labor to purchase and install new equipment and remove and dispose of old equipment including a five percent design contingency. The estimate includes costs for crossing houses complete with racks, crossing controllers, relays and wiring necessary for the control of the wayside equipment. Constant warning time control equipment was included in the estimate due to the variation in speeds between passenger trains and freight trains that will coexist on the line. Wayside equipment has been determined for each location to be either a two- or four-quadrant gate system or flasher-only system with foundations, cable, lights, and bells. A cost for a power service up-grade at each location was included. **All estimated backup details are based on 2014 dollars**. This estimate does not include any costs for the operating contractor (force account), future escalation, contractor's general conditions, overhead, profit, bond, or any other allowances. Other general information and assumptions used in developing this cost estimate include the following:

1. Review of Information contained in the U.S. Department of Transportation (USDOT) Crossing Inventory.
2. Material and labor costs for contractor work are based on various sources, including estimating publications, historical contractor rates from similar projects bids, and experience of the estimators. A material list estimate from Safetran Systems dated 2004 was also used as reference. Material costs from that estimate (where used) were escalated to be consistent with recent cost information.
3. The cost estimate includes assumption of manpower and assumes all work will be done on straight time.
4. The overall cost does not include any credit for salvageable equipment.
5. The cost estimate does not include any cost for upgrades to the wayside signal system.
6. Costs are included for interface at locations where electric switch locks may be required.
7. Cost was added at Crown Street and E. Hollis Street in Nashua between the main line and the branch line specifically for a crossing control interface between the two locations.
8. From the site survey it was observed that the Manchester traffic signals along Canal Street provide signage and a steady flashing yellow light in advance of the crossing for warning of the motorist. Cost for an upgrade to this traffic system is not included.
9. From the site survey it was observed that several locations have traffic signals within 200 feet of the Highway Rail Grade Crossing Warning System and will need to be interconnected to pre-empt the traffic signals in accordance with the Manual on Uniform Traffic Control Devices (MUTCD).

The resulting signal cost estimates for each crossing are shown in Table 1.5.

Table 1.5: Estimated Signal Costs for AHWD Upgrades (2014$)

City	State	Grade Crossing	MP	Cost
Chelmsford	MA	Wotton Street	29.1	$241,750
Chelmsford	MA	Wellman Road	29.6	$260,650
Chelmsford	MA	Cross Street	30.0	$298,576

Bow	NH	Hall Street	71.0	$284,453
Segment Total				**$3,309,669**

Grade Crossing Track Renewals – Each of the highway grade crossings would also be renewed with new track and paving material. The estimated cost for upgrading each of highway grade crossings was based on the average value to upgrade the track and crossing material for six substantial crossings on the MBTA's ongoing Fitchburg Line Improvement Project at $165,950 per crossing.

Bridges – There are 25 railroad bridges along the route between Lowell and Concord spanning an aggregate 2,100 feet over waterways and roadways. The Study team obtained inspection reports, plans, and documentation for each bridge from PAR and the MBTA. The Study team combined this information with selected field inspections to estimate costs to rehabilitate each of the railroad bridges along the route. The assessment of the bridge structures was limited to review and evaluation of this available information only. The scope of this Study does not include bridge inspection and/or development of an independent load capacity rating for any of the bridges. Available information used in the assessment and evaluation of the 25 bridges within the Study limits includes the following:

1. Bridge Inspection Reports obtained from MBCR
2. Bridge Inspection Reports obtained from PAR
3. Bridge Rating Reports obtained from PAR
4. Bridge Plans obtained from PAR
5. Video and photos from a Hi-Rail trip along the rail corridor
6. Photographs of some bridges where access was possible
7. GIS mapping and online aerial photos of the bridges

A Bridge Summary Sheet was developed for each bridge to summarize the basic information and condition of each bridge as identified in available bridge inspection reports. Based on condition ratings, inspector notes and available photographs, a recommended scope of repairs is presented, with concept-level cost item quantities identified. The recommended repairs were also given a weighted rating of "Minor," "Moderate," or "Extensive" based on a subjective evaluation of the available information. Unit costs for various repair/rehabilitation work items were utilized for each of the three weighted ratings, and the appropriate unit cost was then applied to the specific cost item quantity for the given bridge.

The condition of each bridge is summarized in Table 1.6. Bridge repair cost information was developed for the purpose of establishing order-of-magnitude capital investment levels and considered as representative of preliminary conceptual repair/rehabilitation requirements. As project design development advances, more accurate requirements and development of associated costs at each bridge will be required based on further engineering assessment, including hands-on inspections and load capacity ratings for two bridges that have not recently been rated.

Table 1.6: Estimated Bridge Rehabilitation Costs (2014$)

Location		Length (Feet)	Bridge Structure	Deck Type	Spans	Rehabilitation Costs
City/Town	Bridge No.					
Lowell, MA	25.62	30' +/-	Deck Plate Girder	Open	1	$41,000
	25.69	154'-6"	Deck Plate Girder	Open	4	$99,000

	71.54	10'-0"	Reinforced Concrete	RCS	1	$21,000
	73.33	Unknown	I-Beam	Timber	1	$16,000

Stations – Costs for station development were estimated for a number of alternative sites. Estimates relied on unit costs recently generated for a directly applicable peer site. The MBTA Fitchburg Commuter Rail-Wachusett Extension Project is currently under construction. The estimated Wachusett Station construction cost with escalations and contingencies came to $13,303,000 for a station facility with a single-track siding station with one 800-foot high-level side platform and 360 parking spaces.

Detailed costs for Wachusett were used to inform cost estimates for each of the proposed station sites through the use of allocation factors. These include variables such as the number of parking spaces, number of platforms, number of side tracks, square feet of existing wetlands, and whether there was the possibility of contaminated soil disposal. This allowed for the application of the Wachusett station

unit costs even where the characteristics of the sites were different. The costs for a station at the Pheasant Lane Mall site include a parking garage that was estimated at 10 times the cost per space of a surface parking space. This figure is consistent with Jacobs' estimates for other parking garages.

Layover Facilities – Costs to develop layover yards for overnight storage and light maintenance of the service rolling stock were estimated for a number of alternative sites. Estimates relied on unit costs recently generated for a directly applicable peer site. As noted above, the MBTA Fitchburg Commuter Rail-Wachusett Extension Project is currently underway and moving in to construction. The estimated Wachusett layover construction cost with escalations and contingencies came to $13,303,000 for a layover facility with six tracks, including 9,655 track-feet available for the storage of trains.

These detailed costs were used to develop cost estimates for each of the proposed layover facilities through the use of allocation factors. These allocation factors included variables such as the number of storage positions, total track length (feet), and whether there was the possibility of contaminated soil disposal. This allowed for the application of the Wachusett layover facility unit costs even where the characteristics of the sites were different.

Right-of-Way Improvements – Restoration of passenger service on the New Hampshire Main Line will require some right-of-way improvements including relocation of fiber optic lines where new tracks are being restored to the right-of-way, vegetation removal, reestablishing ditches, and cleaning shoulder ballast. The right-of-way hosts three separate private fiber optic installations north from Lowell to Nashua, two between Nashua and Manchester, and one from Manchester north to Concord. Based on the experience of Jacobs' telecommunications engineers, an allowance of $290,400 per route mile was used to estimate the costs of installing replacement fiber optic lines where new tracks were being laid. Allowances for other improvements were derived from earlier studies of the same right-of-way updated to 2014 costs and are listed in Table 1.7.

Table 1.7: Allowances for Right-of-Way Improvements

Right-of-Way Improvement	Unit	Unit Cost (2014$)
Relocate Fiber Optic Lines	Route Mile	$290,400
Vegetation Management	Route Mile	$20,925
Reestablish Ditches	Route Mile	$39,600
Shoulder Ballast Cleaning	Track Mile	$39,930

Positive Train Control – The Rail Safety Improvement Act of 2008 (RSIA) created a new infrastructure requirement for all U.S. commuter railroads. This new requirement should reduce the likelihood of the following:

- Train-to-train collisions
- Injuries to rail roadway workers
- Over-speed derailments
- Accidents due to misaligned switches to sidings

Under the RSIA, all conventional passenger railroads must operate with Positive Train Control (PTC) as soon as possible after December 2015. The MBTA installation of PTC is lagging the 2015 deadline like most of its peers and its ultimate costs are unknown. The Study team employed a 2009 economic analysis prepared by the Federal Railroad Administration (FRA)[1] to account for the cost of PTC, and then escalated the estimates to 2014 at four percent per annum.

At the most basic level, all PTC systems require three equipment elements:

- **Wayside Devices** – Equipment to detect, monitor, and communicate the status of track and switches installed in the field
- **Locomotive/Cab Car Devices** – Equipment to monitor and control train status relative to information on field conditions communicated from central control and wayside equipment
- **Central Office Equipment** – To integrate and communicate information concerning the status of trains, track maintenance crews, switches, signals, and tracks

The relevant work to install onboard locomotive and cab car devices should be completed for the MBTA, PAR, and Amtrak fleets well before the proposed passenger rail service north of Lowell could be implemented. Similarly the PAR and MBTA dispatching offices should have the relevant Central Office Equipment. Any new passenger railway mileage will require the installation of wayside devices.

Using information from the above referenced FRA Study, the Study team conservatively estimated that the more expensive Advanced Civil Speed Enforcement System (ACSES) wayside equipment would be deployed on the route with an average cost of $147,215 per track mile. If Enhanced Traffic Management System (ETMS) is installed, the PTC costs may be lower than estimated here.

Railroad Appliances – Various appliances such as train defect detectors, rail lubricators, and electric locks for hand-thrown turnouts would be required on the refurbished line. Installed unit costs for these appliances and estimated numbers required for each option are listed in Table 1.8.

[1] Roskind, Frank D, Senior Industry Economist, Federal Railroad Administration, Office of Safety Analysis POSITIVE TRAIN CONTROL SYSTEMS: ECONOMIC ANALYSIS. DEPARTMENT OF TRANSPORTATION, FEDERAL RAILROAD ADMINISTRATION, 49 CFR PARTS 229, 234, 235, AND 236 [DOCKET NO. FRA-2006-0132, NOTICE NO. 1] RIN 2130-AC03 July 10, 2009 202 302 9704 pp 112-119 (Retrieved from http://www.fra.dot.gov/downloads/PTC_%20RIA_%20Final.pdf on July 21, 2009)

Table 1.8: Unit Costs and Quantities of Railroad Appliances

Railroad Appliance	Installed Cost (2014$)	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Train Defect Detector	$45,000	1	1	1
Rail Lubricator Unit	$8,000	4	2	6
Electric Locks for Industrial Sidings	$75,000	4	1	5
Electric Locks for Customer Turnouts	$75,000	6	0	12

Multipliers for Allowances – As per typical practice, costs for various professional services and incidental non-itemized expenditures are estimated on the basis of total costs for all rail infrastructure improvements. These multipliers for professional services and incidental work are listed in Table 1.9.

Table 1.9: Professional Services and Incidental Items

Culverts and Retaining Walls	3% of Infrastructure Cost
Environmental (soil disposal, noise abatement, LEED)	3% of Infrastructure Cost
Final Engineering Design	8% of Infrastructure Cost
Construction Phase Engineering Services	4% of Infrastructure Cost

Railroad Services – Mechanisms for estimating the costs for railroad project management, inspections, and protective flagging are reviewed in Table 1.10.

Table 1.10: Railroad Services and Estimated Days of Inspections and Flagging

	Unit Cost	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Railroad Project Management	3% of Infrastructure Cost	N/A	N/A	N/A
Maintenance and Protection of Railroad (Inspections)	$2.00/day	180	90	270
Flagging	$2.00/day	360	180	540

Land – Beyond the railroad right-of-way that will be shared with PAR freight trains, land will be required for stations, parking, and overnight train storage yards. The cost for this land was estimated by consulting local public assessor records in Tyngsborough, Nashua, Bedford, Manchester, and Concord to determine the current assessed value of each parcel that had been identified as necessary for a station or layover yard. Where only a portion of the parcel would be required for the rail facility, Geographic Information System (GIS) tools were used to determine what fraction of the overall parcel would be necessary and to prorate the cost accordingly.

Acquisition of private land for transportation improvements can be a litigious process. An allowance of 220 percent was added to all raw land costs to allow for negotiations, takings, eminent domain, and legal costs. The 220 percent was derived from the Study team's experience working on similar projects in other jurisdictions. New Hampshire's experience may be different. See Table 1.11.

Table 1.11: Assessed Land Value and Estimated Cost (2014$) for Selected Station and Layover Sites

Facility Type	Parcel Size (Acres)	Required Portion	Assessed Value per Acre	Estimated Value	Estimated Cost with 220% Assemblage Factor
Stations					
Tyngsborough	55.640	0.1183	$63,680	$342,380	$1,095,616
Spit Brook Road	40.930	0.2	$510,271	$4,177,080	$13,366,656
Crown Street	6.826	1	$45,224	$308,700	$987,840
Bedford/Manchester Airport or MHT	6.000	0.33	$29,416.67	$444,400	$1,422,080
Granite Street	0.5544	1	$279,132.58	$148,800	$476,160
Stickney Avenue	6.08	1	$237,990	$1,447,000	$4,630,400
Layover Yards					
Spit Brook Road	40.930	0.10	$510,271	$2,088,540	$6,683,328
Manchester	17.7266	0.21	$160,083.55	$592,673	$1,896,555
Stickney Avenue	6.08	1	$237,990	$1,447,000	$4,630,400

Infrastructure Contingency – In accordance with FTA recommendations, a 35 percent contingency was applied to the sum of all infrastructure, engineering, and land costs described above to allow for unforeseen and unusual circumstances that might have been unaccounted for in this engineering cost estimate.

Rolling Stock – Coach requirements were derived using the information concerning the MBTA's current Lowell line ridership and train consist assignments with the Study team's station-by-station weekday ridership estimates to determine which would need additional cars to carry the forecast increase in ridership. Analysis of the schedules also determined that both the Manchester Regional and Nashua Commuter Rail services would require an additional consist in the morning and evening lineups to account for the longer cycle times that service to Nashua or Manchester would entail. The extra train would need to have a locomotive and six coaches.

For the Intercity 8 service, the *Downeaster's* standard consist of four coaches with a locomotive was used as a model. It was further assumed that the Intercity 8 service would operate in the same equipment pool with the *Downeaster's* five train sets adding one more four-car train set, one spare coach, and one spare locomotive to Amtrak's North Station complement.

Equipment requirements for the three final rail service alternatives are summarized in Table 1.12.

Table 1.12: Unit Costs (2014$) and Quantities of Railroad Rolling Stock

Rolling Stock	Purchase Price	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Coaches	$2,530,000	11	6	5
Locomotives	$5,320,000	1	1	2

Trackage Rights – The proposed rail services would be operated on a mix of tracks owned by the MBTA in Massachusetts and by the successors to the Boston and Maine Railroad (B&M) in New Hampshire. The MBTA recently transferred $35 million dollars to PAR in exchange for the right to offer passenger service on B&M/PAR tracks approximately 37 miles north from Tyngsborough, Massachusetts to Concord, New Hampshire. The value of these rights to the MBTA and PAR is approximately $946,000 per route mile. Without these trackage rights the MBTA and NHDOT would need to purchase trackage rights from PAR to operate into New Hampshire. Consequently one of the costs of the project is the $946,000 per route mile one-time trackage fee for every route mile operated into New Hampshire. The estimated value of the MBTA trackage fees for each of the three rail options is summarized in Table 1.13.

Intercity 8 routes operated by Amtrak, in contrast to the MBTA, have statutory rights to operate over every railroad in the nation without paying trackage fees. Consequently, the trackage rights and resulting fees would not be an issue or a cost for Amtrak if Amtrak is the operator of the Capital Corridor intercity rail service.

Table 1.13: MBTA Trackage Right Values by Service Option

	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
MBTA Route Miles in New Hampshire	19	1	0
$946,000/Mile	$18 million	$0.95 million	$0

1.1 Summary of Estimated Rail Costs

Estimated capital costs for each rail service option are summarized below and in Table 1.14.

The **Manchester Regional Commuter Rail Option** is projected to cost $143 million for infrastructure and land plus $50 million contingency allowance. The option cost also includes $33 million in rolling stock and $18 million in trackage rights that would be contributed by the Commonwealth of Massachusetts.

The **Nashua Minimum Commuter Rail Option** is projected to cost $73 million for infrastructure and land plus $26 million contingency allowance. The option cost also includes $20 million in rolling stock that would be contributed by the Commonwealth of Massachusetts. The value of the Massachusetts trackage rights for this option is $0.95 million as it would use roughly one mile of PAR right-of-way in New Hampshire to access a station and/or a layover facility at the Spit Brook Road site.

The **Intercity 8 Option** is projected to cost $172 million for infrastructure and land plus a $60 million contingency allowance. The option cost also includes $23 million in rolling stock that would be the responsibility of NHDOT. This option may be operated by Amtrak and, therefore, the value of Massachusetts acquired trackage rights would be zero since Amtrak has statutory authority to operate without acquiring trackage rights from PAR.

Table 1.14: Summary of Projected Capital Costs (2014$)

	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Main Line Tracks	$29.7	$15.3	$42.1
Track Switches	$6.4	$2.8	$7.8
Interlockings	$10.6	$5.1	$12.0
Block Signals	$1.0	$0.4	$1.2
Grade Crossing Signals	$5.0	$1.4	$8.3
Grade Crossing Track Renewals	$3.3	$0.8	$5.6
Bridges	$10.7	$2.1	$15.4
Stations	$20.8	$6.3	$18.7
Layovers	$12.4	$13.4	$4.8
Right-of-Way Improvements	$6.2	$2.9	$8.8
Positive Train Control	$6.5	$2.9	$9.5
Railroad Appliances	$0.5	$0.1	$1.0
Direct Construction Expense Subtotal	**$113.3**	**$53.7**	**$135.2**
Multipliers for Allowances	$20.4	$9.7	$24.3
Railroad Services	$4.5	$2.1	$5.7
Land for Stations	$1.2	$0.3	$0.9
Land for Layovers	$0.6	$2.1	$1.4
Assemblage Allowance (220%)	$4.0	$5.3	$5.2
Subtotal Land	**$5.9**	**$7.8**	**$7.5**
Contingency	$50.0	$25.6	$60.5
Grand Total (infrastructure)	**$194.5**	**$98.9**	**$233.2**
Coaches	$27.8	$15.2	$12.7
Locomotives	$5.3	$5.3	$10.6
Grand Total (rolling stock)	**$33.2**	**$20.5**	**$23.3**
Trackage Rights	**$18.0**	**$0.9**	**$0.0**
Total Project Value	**$245.6**	**$120.3**	**$256.5**

Bus – Final estimates of capital costs for the bus options revolved around the same two factors applied to derive the preliminary estimates: additional buses required to operate more frequent service and the roadway upgrades required to allow for bus on shoulder operations providing faster peak service for some options.

As noted for the preliminary options, some bus service improvement options entailed increasing the frequency of bus service. These services would require additional rolling stock to operate. The Study team estimated the required number of additional buses by consulting with NHDOT and BX to

determine the size and utilization of the current BX fleet. Study team analysis indicated that amending the current schedule of peak service to operate direct non-stop half-hourly peak service from all six park-and-ride lots currently served by BX would require an addition of 16 buses to BX current fleet of 22 vehicles as shown in Table 1.15.

Table 1.15: BX Vehicle Requirements by Service Option

	Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
Vehicles to Operate Minimum Service (VOMS)	16	30	16	30
Fleet	22	38	22	38
Spares	6	8	6	8
% Spare	27%	21%	27%	21%

A preliminary estimate of $400,000 was included for new vehicles, but NHDOT informed the Study team that new vehicles would be expected to cost $600,000 each. Study team work on existing highway conditions found sufficient shoulder width for the 22 affected route miles between I-495 and Somerville, Massachusetts along I-93 to allow Bus on Shoulder operations without substantial investment in new right-of-way. A preliminary estimate of $100,000 per route mile[2] had been used based on early experience in Minnesota. For the final estimate a more recent figure of $250,000 per route mile[3] (2007 dollars) was employed. Consistent with FTA guidance, a 35 percent contingency was applied to projected infrastructure costs (see Table 1.16).

Table 1.16: Final Capital Cost Estimates for Bus Options (In Millions, 2014$)

	Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
Vehicles Cost (millions) *	$0.0	$9.6	$0.0	$9.6
Infrastructure Cost (millions) **	$0.0	$0.0	$7.4	$7.4
Total Capital Cost (millions)	$0.0	$9.6	$7.4	$17.0

** New coaches at $600,000 each*
*** Infrastructure cost of $250,000 per route mile plus a 35% contingency allowance*

1 Final Estimates of O&M Cost

Refined O&M cost estimates were prepared for more detailed final analysis of the two commuter rail, one intercity rail, and three bus options that advanced through preliminary screening: Manchester Regional Commuter Rail, Nashua Minimum Commuter Rail, Intercity 8, Bus on Shoulder, Expanded Base, and Expanded Bus on Shoulder.

1.1 Commuter Rail

The Study team revisited the operating conditions for each of the three remaining rail options in meetings with Pan Am Railways (PAR), Massachusetts Department of Transportation (MassDOT), Massachusetts Bay Transportation Authority (MBTA), and New Hampshire Department of Transportation (NHDOT) and was able to refine the service characteristics based on their feedback. The O&M costs evolved over the course of preliminary stages of the Study, but did not change significantly. The total number of weekday vehicle miles and weekday revenue miles changed slightly as the options were refined. Two additional elements where changes were applied are in the calculation of unit costs and fare revenue. The operating cost data for the commuter rail options in Table 1.1 were updated to 2012 National Transit Database (NTD) figures from the 2009 NTD values used for the preliminary estimates.

Table 1.1: Derivation of Final Estimates of Commuter Rail Operating Costs

	Reported Annual Cost	Units	Reported Quantity	Ratio	% Variable	Variable Cost Ratio
Operations	$107,909,000	Train Miles	3,947,889	$27.33	85%	$23.23
Mechanical	$88,208,552	Peak Vehicles	416	$212,039.79	85%	$180,234
Locomotive Maint.	$32,045,720	Locomotives	60	$534,095	85%	$453,981
Coach Maintenance	$47,534,485	Coaches	356	$133,524	85%	$113,495
Infrastructure Maint.	$93,677,312	Track Miles	712	$131,661.72	85%	$111,912

Based on 2012 Financial Reports of MBTA to Federal Transit Administration

These values were used to describe each service option to estimate the O&M cost drivers for each commuter rail option. These cost drivers are train miles, rolling stock fleet size (locomotives and coaches), and track miles (see Table 1.2).

Table 1.2: Cost Drivers Used for Final Estimates of Commuter Rail Operating Costs

Commuter Rail Option	Weekday Train Miles	Morning Peak Locomotives	Morning Peak Coaches	Track Miles
Manchester Regional Commuter Rail	1,843	5	36	97.4
Nashua Minimum Commuter Rail	1,298	4	24	72.8
Increments Above Base Service				
Manchester Regional Commuter Rail	573	1	11	44.4
Nashua Minimum Commuter Rail	28	0	6	19.8

An annualization factor of 254.25 weekday equivalents per annum was used to convert weekday train miles into an estimate of annual train miles. No weekend or holiday service was included in the commuter rail operating cost, ridership, or revenue estimates. The product of the cost drivers multiplied by the cost factors for each service option yielded the two final operating cost forecasts shown in Table 1.3.

Table 1.3: Final Estimates of Commuter Rail Operating Costs (In Millions, 2012$)

Commuter Rail Option	Operations	Mechanical Maintenance	Infrastructure Maintenance	Total
Manchester Regional	$3.75	$2.07	$4.97	$10.78
Nashua Minimum	$1.04	$0.83	$2.22	$4.08

1.2 Intercity 8

The Intercity 8 service option that advanced through preliminary screening was developed to the same level-of-detail as the commuter rail service options, including estimates of daily train miles, rolling stock requirements, track miles required, number and location of stations, and schedules of service.

The most recent data (2012) on the *Downeaster* service indicated that it costs roughly $36 per train mile to operate. This metric is roughly equivalent to the costs applied for Midwestern and New York/Vermont services reviewed in the studies recommended by Amtrak. Using the simple cost of $36 per train mile, the estimates of operating cost in Table 1.4 were derived for the three intercity service options.

Table 1.4: Derivation of Final Estimates of Intercity Rail Operating Costs (2012$)

Intercity Service Option	Trips per Day	Train Miles per Day	Train Miles per Year	Annual Operating Cost (@ $36/train mile)
Intercity 8	8	586	214,036	$7,705,296

1.3 Commuter Bus

Weekday service schedules developed for each of the three commuter bus options did not change after the preliminary screening. The estimates of vehicle requirements and revenue miles, however, did change slightly as the options were refined. The variables used to estimate the annual operating costs for the three service options as summarized in Table 1.5.

Table 1.5: Derivation of Final Estimates of Commuter Bus Operating Costs (2012$)

Service Statistics and Costs	Base Service	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder
Peak Vehicles	16	30	16	30
Total Fleet including Spares	22	38	22	38
Revenue Vehicle Miles Travelled	1,286,685	1,914,368	1,286,685	1,914,368
Fuel, Crew and Supervision per RVMT	$4.17	$4.17	$4.17	$4.17
Maintenance Expense per Coach	$27,032	$27,032	$27,032	$27,032
Vehicle Maintenance Expense	$594,704	$1,027,216	$594,704	$1,027,216
Vehicle Operating Expense	$5,364,033	$7,980,768	$5,364,033	$7,980,768
Preliminary Estimate of Total Expense	**$5,958,737**	**$9,007,984**	**$5,958,737**	**$9,007,984**

Summary of Final Estimates of O&M Costs – The final estimates of *incremental* O&M cost for each rail and bus service option are found in Table 1.6.

Table 1.6: Final Estimates of Annual Incremental O&M Costs (In Millions, 2012$)

Service Option	Total
Commuter Rail	
Manchester Regional	$11
Nashua Minimum	$4
Intercity Rail	
Intercity 8	$7.7
Bus Service	
Expanded Base	$3
Bus on Shoulder	$0
Expanded Bus on Shoulder	$3

Table 1.1: Manchester Regional Commuter Rail Daily Boarding Estimates 2
Table 1.2: Nashua Minimum Commuter Rail Daily Boarding Estimates 2
Table 1.3: Daily Ridership Estimates 2

1 Rail Ridership Forecast Methodology and Results

This document describes the Capitol Corridor rail ridership forecasting model development and presents forecasts for the Manchester Regional Commuter Rail and Nashua Minimum Commuter Rail alternatives.

1.1 Model Development

The forecast models use the existing Massachusetts Bay Transportation Authority (MBTA) commuter rail system to estimate parameters for forecasting commuter rail boardings on the proposed New Hampshire extensions of the MBTA system.

Multiple models were estimated with parameter inputs, including rail operations data (service frequency, headway, travel time), station characteristics (parking, highway access, transit service, distance between stations, distance to Boston), socio-economic data (population, household income, vehicle ownership, employment), the Census Transportation Planning Package (CTPP) journey-to-work (JTW) data, and available MBTA system boarding data. A recommended model was selected from the estimated models based on the following:

- **Model Statistical Performance:** The model must be statistically valid.
- **Expected Relationships between Model Parameters:** The model must make sense. If an additional train is provided in the peak period, daily boards should increase more than if the additional train was provided in the off-peak period.
- **Expert Opinion:** A set of statistically valid models was developed and reviewed by the Study team. These models were presented to the FTA, which approved the preferred model.

The recommended model inputs and the reasons why each are used are discussed below.

- **Frequency of peak and off-peak trains** accounts for the impacts of differing levels of service on ridership. Trains in the peak direction during peak travel times are expected to attract more riders than trains during off-peak times and direction. A train is considered to be a peak train if it arrives in Boston between 6:00am and 9:30am or if it departs Boston between 4:00pm and 7:00pm. The inclusion of the peak and off-peak frequency in the model allows the model to be sensitive to the differing frequency of service in the commuter rail alternatives.
- **JTW data** provide information on the size of the work market to Boston around each station. JTW trips to downtown Boston are associated with the closest commuter rail station where riders would board if they were to use commuter rail to go to work. The inclusion of the JTW data provides a measure of the number of workers who could possibly use the proposed rail service.

- **Employment around the station** informs the potential for a station to attract trips other than those destined for Boston, such as reverse/intermediate commute trips and non-work related trips. The total employment within a half-mile of each station is calculated. A half-mile buffer is used to allow for walk access to the employment location.
- **Park-and-Ride (P&R) station designation** accounts for the impacts of parking availability. A P&R station is characterized as having a large parking lot that is not located in a densely developed area. MBTA P&R stations have a greater number of boardings than non-P&R stations. The inclusion of a P&R designation allows the model to be sensitive to the differences in the proposed stations, with the South Nashua and Bedford/Manchester-Boston Regional Airport (Manchester Airport or MHT) stations designated as P&R lots in the alternatives.

1.2 Model Forecasts

Opening day forecasts on the Manchester Regional Commuter Rail and Nashua Minimum Commuter Rail commuter alternatives are presented below in Tables 1.1 and 1.2. The model results are presented with a forecast value and an upper and lower bound that are the 95 percent confidence interval around the forecast value. It is important to note that, as with all forecasts, the predictions are not a single value, but rather a range of possible values.

Table 1.1: Manchester Regional Commuter Rail Daily Boarding Estimates

Station	Forecast	Lower Bound	Upper Bound
Manchester, NH	270	180	390
Bedford/MHT	280	230	350
Nashua	420	330	540
South Nashua	590	440	800
Total	**1,560**	**1,180**	**2,090**

Table 1.2: Nashua Minimum Commuter Rail Daily Boarding Estimates

Feeder Bus Weight	Forecast	Lower Bound	Upper Bound
South Nashua	590	450	770

The estimated model predicts the daily boards for each of the proposed stations. These boards represent one-half of a daily round trip. To convert these boarding data to daily ridership, a factor of two is applied to account for the second-half of the round trip.

Table 1.3: Daily Ridership Estimates

Alternative	Ridership	Lower Bound	Upper Bound
Manchester Regional Commuter Rail	3,130	2,350	4,170
Nashua Minimum Commuter Rail	1,170	890	1,540

Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs more "car-light" mobility options
- Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences

Task Objectives

This task completes the technical analysis and decision-making process that comprise the AA Study's two main elements. The Study began with the Purpose and Need Statement (Task 2, Appendix 2 to the AA Final Report), which was a detailed definition of transportation and related problems that the alternative transit investment strategies were intended to address. The initial set of options, both rail and intercity bus, were defined in Task 4, Initial Conceptual Transit Alternatives (Appendix 4 to the AA Final Report). Those preliminary investment plans were then subjected to comparative evaluation, based on preliminary estimates of costs (both capital and operating) and benefits, including ridership, economic development, land use, and environmental impacts. This process led to the selection of seven alternatives for more rigorous analysis and evaluation (Task 5, Preliminary Evaluation of Conceptual Alternatives and Recommended Alternatives for Detailed Evaluation; Appendix 5 to the AA Final Report). The criteria used to evaluate the intermediate options were detailed in Task 6, Evaluation Criteria and Methodology (Appendix 6 to the AA Final Report). Finally, those alternatives were refined and assessed

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

in great detail, a process discussed in Task 7, Detailed Evaluation of Alternatives (Appendix 7 to the AA Final Report).

That logical, sequential, analytical and selection process culminated in the selection of the recommended investment strategy through the application of assessments coming out of Task 7. While the term Locally Preferred Alternative (LPA) is commonly used to describe the recommended transit strategy resulting from an alternatives analysis such as the Capitol Corridor Study, it is probably more accurate to describe the recommended course of action as a comprehensive locally selected transit or intercity rail investment strategy, consisting of discrete investments, often implemented over a defined period of time. That is the case with the plans recommended for the Capitol Corridor.

This task had four purposes:

1. Describe each evaluation criterion, focusing on those most influential in driving selection of the preferred investment strategy
2. Describe each of the seven final alternatives, focusing on strengths and weaknesses relative to competing alternatives
3. Identify factors most important in determining the selection of the preferred strategy, the major differentiators
4. Describe the preferred investment strategy

1 The Intermediate Alternatives

Seven intermediate alternatives were discussed in detail in Task 5 (Appendix 5 to the AA Final Report):

1. **No Build**. Existing intercity bus service, Concord-Manchester-Boston via I-93 and Route 3; there is no additional investment
2. **Manchester Regional Commuter Rail.** Downtown Manchester-Manchester Airport-Nashua-Nashua South-Boston; eight round trips per weekday to Manchester, 17 to Nashua
3. **Nashua Minimum Commuter Rail**. Nashua South-Boston; eight round trips
4. **Intercity 8**. Intercity rail service, Concord-Downtown Manchester-Manchester Airport-Nashua-Boston; four round trips
5. **Expanded Base**. Manchester-Boston; 20 additional round trips
6. **Bus on Shoulder**. Existing intercity bus service running on reserved shoulder lanes on I-93 in Massachusetts
7. **Expanded Bus on Shoulder**. Expanded service noted above using shoulder lane in Massachusetts

(During completion of the Study there was discussion by New Hampshire officials of extending Massachusetts Bay Transportation Authority [MBTA] service from Lowell to Tyngsborough, Massachusetts, immediately south of the state line, with the expense being entirely borne by Massachusetts. However, there is no reference to such service in Massachusetts transportation plans,

and there was no discussion of the subject during extensive discussions between the Study team and Massachusetts transit officials. The MBTA never broached the subject.)

2 Evaluation Criteria

The seven final alternatives were evaluated against five technical criteria analyzed in detail in Task 7/Appendix 7 to the AA Final Report:

1. **Costs, both capital and operations and maintenance (O&M)**. What would it cost to implement each option, including land acquisition, construction, and equipment (buses or trains)? And what would it cost, annually, to operate each alternative?
2. **Mobility impacts, primarily ridership**. How many passengers would ride the new service? And especially, how many new riders (in addition to current transit riders) would the service attract within New Hampshire?
3. **Environmental and equity impacts**. What are the major differences among alternatives in terms of environmental and equity impacts, both positive and negative?
4. **Land use**. What are the differences among alternatives in terms of their likelihood of promoting more compact, sustainable development, especially near stations?
5. **Economic development**. What would be the relative impact of each option in terms of enhancing the New Hampshire economy, as measured by new employment, new residential construction, and commercial development?

In addition to technical evaluations, in assessing the alternatives the Study team considered extensive input from the public and key stakeholders, including business leaders; regional planning commissions; elected officials at local, state, and national (U.S. Senate and House of Representatives) levels; and the Federal Railroad Administration and Federal Transit Administrations (FRA and FTA, respectively). Finally, the team considered input from existing transit providers, Boston Express (BX)/Concord Coach and MBTA, and was also guided by its extensive experience working on similar analyses in regions throughout the U.S. and by the extensive record of research conducted over decades on major transit projects in the U.S.

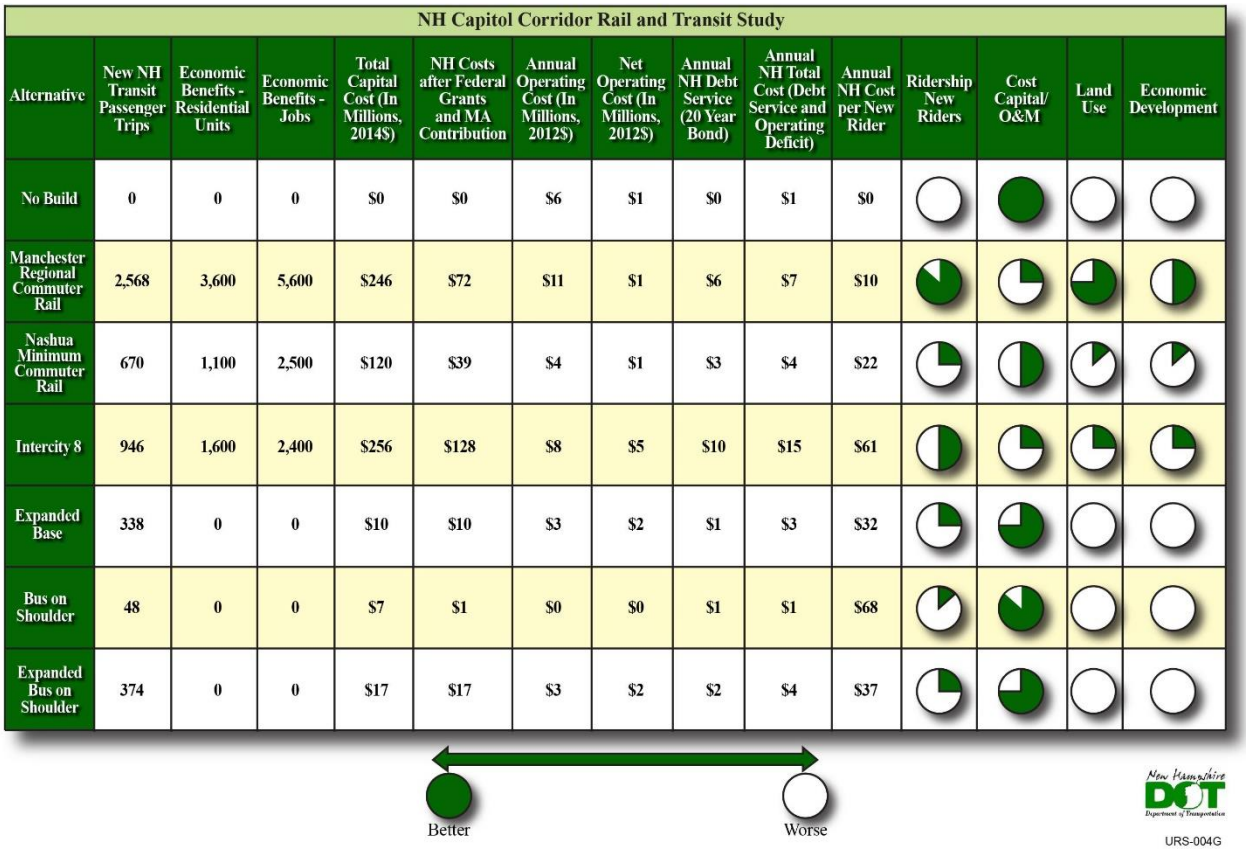
3 Evaluation of the Intermediate Alternatives

The results of the comparative evaluation of the seven alternatives are summarized in Table 3.1. The remainder of this section is a detailed discussion of that summary table. Evaluation and analysis led to the selection of the preferred investment strategy for the New Hampshire Capitol Corridor, as presented in the following, and concluding, section of this report.

The vertical axis of the table includes the seven final alternatives, as listed above in Section 1. The horizontal axis includes key evaluation criteria, including several critical performance measures derived from results of the analyses. It is important to note that the focus is on those factors that are most important in drawing critical differences among alternatives or, in some cases, among sets of

alternatives. Thus, for example, although environmental impacts – both positive, such as reduced air pollution resulting from fewer cars on the road, and negative, such as noise from railroad locomotives – are important, they did not constitute a major differentiator among alternatives studied.

Table 3.1: Final Screening of Alternatives



NH Capitol Corridor Rail and Transit Study

Alternative	New NH Transit Passenger Trips	Economic Benefits - Residential Units	Economic Benefits - Jobs	Total Capital Cost (In Millions, 2014$)	NH Costs after Federal Grants and MA Contribution	Annual Operating Cost (In Millions, 2012$)	Net Operating Cost (In Millions, 2012$)	Annual NH Debt Service (20 Year Bond)	Annual NH Total Cost (Debt Service and Operating Deficit)	Annual NH Cost per New Rider	Ridership New Riders	Cost Capital/ O&M	Land Use	Economic Development
No Build	0	0	0	$0	$0	$6	$1	$0	$1	$0				
Manchester Regional Commuter Rail	2,568	3,600	5,600	$246	$72	$11	$1	$6	$7	$10				
Nashua Minimum Commuter Rail	670	1,100	2,500	$120	$39	$4	$1	$3	$4	$22				
Intercity 8	946	1,600	2,400	$256	$128	$8	$5	$10	$15	$61				
Expanded Base	338	0	0	$10	$10	$3	$2	$1	$3	$32				
Bus on Shoulder	48	0	0	$7	$1	$0	$0	$1	$1	$68				
Expanded Bus on Shoulder	374	0	0	$17	$17	$3	$2	$2	$4	$37				

In considering the evaluation factors used in this report, it is also important to look for *major* differences among alternatives and groups of alternatives. Despite the apparent precision of the numbers regarding costs and benefits, they are, in fact, estimates, with margins of error. Thus, a difference of, for example, 100 riders per day between two options should be seen as no difference; they are equivalent. The same could also be said about a difference in capital cost of, for example, $10 million.

The remainder of this section will consist of, first, a column-by-column discussion of the evaluation factors in Table 3.1, followed by a row-by-row discussion of the alternatives, and concluding with a listing of the most important differences among those options.

3.1 Transit Ridership

Task 7 (Appendix 7 to the AA Final Report), Detailed Evaluation of Alternatives, includes a very detailed evaluation of ridership forecasts for each alternative: a breakdown of ridership for each station, as well as totals for each option. For purposes of selecting the preferred investment strategy, the focus is on

new transit passenger trips to and from New Hampshire, which are riders in addition to those on existing intercity bus service. This is considered to be the best measure of transportation benefits for the state. By that measure, Manchester Regional Commuter Rail service outperforms all other options, with approximately 2,570 new New Hampshire riders per weekday, almost all of whom are going to or from Boston. The other two rail alternatives are a distant second and third, with the three bus options having about half or fewer riders than the weakest rail option, Nashua Minimum Commuter Rail.

3.2 Economic Benefits

Economic benefits were also discussed in great detail in Task 7 (Appendix 7 to the AA Final Report). Here, the focus is on the number of new residential units around new stations, especially strong in downtown Manchester and a potential Spit Brook Road station in Nashua, and on new jobs resulting from service implementation. Both measures point to a similar conclusion: Manchester Regional Commuter Rail clearly outperforms the other two rail options, with Nashua Minimum Commuter Rail being a distant third. The bus options do not produce significant economic benefits, the reasons for which are discussed in Task 7 (Appendix 7 to the AA Final Report). This overall picture is consistent with experience both nationally and in New England.

3.3 Financial Costs

The column for total capital cost shows that the rail options are all significantly more expensive than any of the bus alternatives, with Manchester Regional Commuter Rail and Intercity 8 both at about $250 million, double the Nashua Minimum Commuter Rail service, and far above the bus range of $7 to $17 million.

The next cost column is New Hampshire costs after federal grants and Massachusetts contributions. The assumption is, as is typically the case with a project such as this, that approximately half of the capital cost of the rail alternatives will be covered by federal contributions. And, since the two commuter rail options are extensions of existing Boston-Lowell service, the MBTA (the presumed operator) would also share some of the costs. The resulting numbers reflect similar ratios to the total costs, though at a much lower level, at most half of the total. Among rail options, Nashua Minimum Commuter Rail is half the cost of Manchester Regional Commuter Rail, with the still-highest Intercity 8 number reflecting the absence of a Massachusetts contribution.

The two operating cost columns, total annual and net after fares and other revenues, show that the net operating costs are all $2 million or less, with the exception of the Intercity 8 at $5 million.

The assumption, again a typical one, is that the state would issue bonds to cover the capital cost not covered by federal or Massachusetts support. The column labeled annual “NH Debt Service” reflects the annual cost of paying off the debt, and also portrays the higher cost of all the rail options, highest for Intercity 8 and Manchester Regional Commuter Rail, all much higher than any bus alternative.

Finally, by adding the net operating cost and debt service the result is the state’s total annual cost, and answers that vital question: What is the total amount that New Hampshire would need annually to build and operate each alternative? The number ranges from $6 to $15 million for the rail options (Intercity 8 highest, Nashua Minimum Commuter Rail lowest) to $1 to $4 million for the bus alternatives.

3.4 Cost/Benefit

The Capitol Corridor AA Study is essentially a large cost/benefit exercise with fairly large ranges of both, and with benefits tending to increase along with costs. For the purpose of helping to select the preferred alternative for the corridor, probably the single best measure of cost/benefit is the annual cost to New Hampshire to obtain each new rider. Results are shown in the final numerical column. They show that – other than the No Build option, which is very low for both costs and benefits – the Manchester Regional Commuter Rail has the lowest (best) ratio of about $14 million, followed, distantly, by Nashua Minimum Commuter Rail and the two expanded bus options, all essentially the same. The highest (worst) cost per new rider is Intercity 8.

3.5 Qualitative Assessment Summary

The final four columns on Table 3.1 summarize the relative performance of the alternatives against four important evaluation criteria: new New Hampshire riders, costs (capital and O&M), land use impacts, and economic development potential. They reflect relative performance in that the alternatives are judged against each other, not by any national standard. They also reflect the calculations discussed above for costs and benefits, and the collective professional judgment of the Study team, especially regarding land use impacts, specifically the likelihood that an alternative will promote denser, mixed-use development (Transit-Oriented Development or TOD) near stations. This subject is discussed in detail in Task 7 (Appendix 7 to the AA Final Report). That judgment reflects experience working on similar projects in New Hampshire and throughout the U.S.

The use of the shaded circles helps provide a quick visual summary of each option's strengths and weaknesses. A full circle indicates a very strong performance and an empty circle a very weak performance, with gradations reflecting intermediate performance. Basically, the darker a circle, the stronger an alternative is within that evaluation criterion.

3.6 Alternatives: Relative Strengths and Weaknesses

3.6.1 No Build (No Additional Transit Service)

Strengths: By far, this option's great strength is that there would be no incremental cost. It should be noted that the No Build option continues successful intercity bus service on both the I-93 and Route 3 corridors.

Weaknesses: Its greatest weakness is the opportunity cost of not addressing the transportation and other problems discussed in the Study's Purpose and Need Statement (Appendix 2 to the AA Final Report). Essentially, there are the social and economic costs of not receiving the benefits resulting from investments in transit improvements. There would be no congestion relief, environmental benefits, or economic benefits resulting from the attraction of new residents and employees.

3.6.2 Manchester Regional Commuter Rail

Strengths: In terms of benefits alone, the Manchester Regional Commuter Rail service outperforms all other alternatives in all evaluation categories, often by a wide margin. Its new New Hampshire ridership total is two and one-half times the second best option, Intercity 8. Because it provides service to

Manchester, with its dense core and an existing "feel" of TOD, and its higher service level than Intercity 8, this option would have a stronger impact on land use and economic development. And the alternative's cost per new rider (cost for New Hampshire) is half that of its closest competitor, Nashua Minimum Commuter Rail.

Weaknesses: All those benefits come with a price tag, and the Manchester Regional option, together with Intercity 8, is the most expensive for both capital and O&M.

3.6.3 Nashua Minimum Commuter Rail

Strengths: This alternative was designed to answer the frequently asked question: What is the least expensive rail option that passes any test of reasonableness? Therefore, its major – perhaps only – benefit is low cost and, possibly, the ease of implementation, perhaps as phase one of the Manchester Regional Commuter Rail alternative. Its capital cost is half that of the other two rail options, although, partly because of its relatively poor ridership, the annual cost to New Hampshire is 60 percent of the Manchester Regional service. Finally, given its relatively low cost, this option could be eligible for federal funding from programs that would not be available for more expensive rail options.

Weaknesses: Nashua Minimum Commuter Rail's low (financial) cost also comes with relatively poor performance compared with other rail options, in terms of ridership, land use, and economic development impacts. Especially noteworthy is the new daily ridership total of 670, versus 2,570 for the Manchester Regional service, and, consequently, a cost-per-new-rider that is two and one-half times that for the Manchester Regional service.

3.6.4 Intercity 8

Strengths: This is the only rail alternative that provides service to Concord, as well as to downtown Manchester, although with fewer trains than the Manchester Regional Commuter Rail. Therefore, it outperforms the Nashua Minimum Commuter Rail and all bus alternatives in terms of land use and economic development and ridership, but trails Manchester Regional service by a wide margin.

Weaknesses: This is the highest-cost alternative in terms of capital, net operations, and total annual cost to New Hampshire (at least 50 percent higher than all other build options), which is especially noteworthy given its relatively weak service level and ridership performance. One reason for the high cost is the assumption that the project would include the purchase of new train sets, with no support from Massachusetts. Finally, there are two potential issues with the MBTA south of Lowell: capacity for additional trains on shared trackage between Lowell and Boston and availability of capacity at North Station for additional trains.

3.6.5 Intercity Bus Improvements

Strengths: New Hampshire already has strong bus service to Boston (directly to South Station and Logan Airport) from Concord, Manchester, and Nashua. The three bus alternatives considered in the Capitol Corridor AA Study would improve service by adding buses and/or running buses on reserved shoulder lanes on I-93 in Massachusetts. The major benefit is low cost: All three options are the least costly by far

in terms of capital, between $7 and $17 million, although net operating costs for expanded service are similar to rail.

Weaknesses: As noted above, costs and benefits tend to rise – and fall – together. Improved bus service, especially with Bus on Shoulder implemented by Massachusetts, is inexpensive, but the benefits are minimal. (Note that what is important here are benefits above the considerable mobility benefits from existing bus service.) Ridership gains for all three bus options are well below those of the rail alternatives and, as noted above and in detail in Task 7 (Appendix 7 to the AA Final Report), economic development and land use benefits resulting from intercity bus service, in New England and throughout the country, are minimal.[2]

(Note: If passenger rail service is implemented, some existing bus riders would shift from bus to rail, possibly allowing for a reduction in existing bus service, especially on Route 3, where the rail line closely parallels the highway. This would, of course, reduce overall costs for combined rail-bus transit service in the corridor. This issue is discussed in detail in Task 7(Appendix 7 to the AA Final Report), and the Study team recommends further discussion of modifying – or retaining some or all – bus service if a rail project is adopted.)

4 Recommended Strategy

Based on the analysis completed for this Study, including the evaluation discussed in this chapter, and on the progress made in the decision-making process in New Hampshire, the Study team concluded that additional discussion, debate, and input by state policymakers is required before a definitive decision on next implementation steps can be made. In the context of moving toward and making that recommendation, it is especially important that further progress be made on a financial plan, or plans, that could include federal, state (New Hampshire and Massachusetts), and local support. (A discussion of potential funding sources is contained in the financial analysis in Task 3, Appendix 3 to the AA Final Report.)

To help guide that process, the Study team recommended narrowing the range of options to five: No Build, Manchester Regional Commuter Rail, Nashua Minimum Commuter Rail, Intercity 8, and Bus on Shoulder operation for existing intercity bus service on I-93 in Massachusetts. Each of these was evaluated above, and the strengths and weaknesses of each, as noted in that evaluation, should serve as the basis of the ongoing public debate.

The rationale for selecting each option recommended for further review follows:

- **No Build**. Maintenance of the status quo, which includes existing intercity bus service, obviously is the lowest-cost (in terms of new investment dollars) alternative of all those considered.

[2] An important note on ridership: Ridership gains result far more from the addition of more buses than from reliability improvements stemming from shoulder operation in Massachusetts

- **Manchester Regional Commuter Rail**. From an effectiveness standpoint (consideration of the complete range of benefits), this option is clearly the strongest alternative considered in the Study. It performs very well in terms of ridership, economic development impact, and land-use impact. However, on the cost side, it is one of the most expensive options.
- **Nashua Minimum Commuter Rail**. This is the lowest-cost rail option. And while it does not stand out in terms of ridership and economic or land-use impacts, it could serve as the first phase of the implementation of Manchester Regional Commuter Rail service.
- **Intercity 8**. This was judged to be the preferred intercity rail option of the three assessed earlier in the Study. Intercity 8 is the lowest-cost option of the intercity alternatives considered and, if implemented, could serve as the first phase of more robust service, following the implementation strategy for the original Amtrak Portland-Boston *Downeaster* service. As a relatively expensive alternative, this would require federal support for capital costs. While there is currently no source for such funds, that situation could change, as then could the prospects for Intercity 8 development.
- **Bus on Shoulder (for existing intercity bus service)**. This is an option low on cost and low on benefits. It is also dependent on a decision by Massachusetts, as construction of any required Bus on Shoulder lanes on I-93 would be in the Commonwealth close to Boston. The possibility of financial support from New Hampshire for this strategy should be part of the forthcoming policy discussion, as should the potential for reducing existing bus service if rail is implemented, as discussed in Task 7 (Appendix 7 to the AA Final Report).

During future discussions, it should be noted that the recommended options do not have to be considered as a single investment package. Bus on Shoulder could be implemented without movement on passenger rail. And rail could be recommended without action on Bus on Shoulder. Similarly, Nashua Minimum Commuter Rail could be adopted as the first phase of the Manchester Regional Commuter Rail service – or as an independent project on its own merit. And Manchester Regional Commuter Rail service could be recommended with or without phasing.

In terms of next steps, specific project development actions will emerge as policymakers get closer to a recommended strategy, since alternative strategies can have very different requirements for engineering, project development, and management, including the identification of governance entities to lead implementation activities and operations.

To conclude, it should be emphasized again that it is critical during discussion of the remaining options that serious thought be given to, and progress be made on, a realistic financial plan, options for which are discussed in Task 3 (Appendix 3 to the AA Final Report). This is necessary for any progress to be made on implementation and for the procurement of federal funding, which is assumed to be necessary for any of the more expensive alternatives.

1 Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs more "car-light" mobility options
- Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences

2 Task Objectives

Service development planning is the technical analysis of new passenger rail (and related public transportation) services by progressively narrowing the set of reasonable alternatives that can best meet corridor needs. The Service Development Plan (SDP) lays out the overall scope and approach for the proposed service alternative as selected through the National Environmental Protection Act (NEPA) screening process. Primary SDP objectives include the following:

- Clearly demonstrate the Rationale for new or improved passenger rail service
- Summarize analysis of the proposed new or improved passenger rail service and describe the alternative that would best address the Rationale and Purpose and Need as identified through the NEPA process

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

- Demonstrate the operational and financial feasibility of the new service
- As applicable, describe how SDP implementation may be divided into discrete phases

This Capitol Corridor AA Study was jointly funded by the Federal Transportation Agency (FTA) and Federal Railroad Administration (FRA) to ensure the broadest possible universe of alternatives was considered to address the corridor's transportation issues. While these two funding streams supported one Study, each agency designated use of their funds for specific tasks and geographies. This SDP responds to the FRA's desire to identify and implement corridor projects and programs that will achieve four results:

1. Serve as a catalyst for growth in regional economic productivity and expansion by stimulating domestic manufacturing, promoting local tourism, and driving commercial and residential development
2. Increase mobility by creating new choices for travelers in addition to flying or driving
3. Reduce national dependence on oil
4. Foster livable urban and rural communities

This project also lays the groundwork for developing future intercity rail services north – from Boston into New Hampshire and beyond. A Passenger Rail Corridor Investment Plan (PRCIP), including preparation of a NEPA environmental review, will become the foundation for potential future efforts (i.e., engineering design, environmental reviews, permitting, and construction).

3 SDP Report Organization

This SDP is composed of 10 sections:

- Rationale, Goals, and Objectives
- Existing Corridor Conditions
- Service Alternatives
- Market Analysis
- Preferred Intercity Rail Service Design and Operations
- Preferred Intercity Rail Stations and Layover Facilities
- Preferred Intercity Rail Required Capital Improvements and Capital Costs
- Forecast Operating Costs and Revenues
- Preferred Intercity Rail Public Benefits
- Preferred Intercity Rail Implementation and Finance

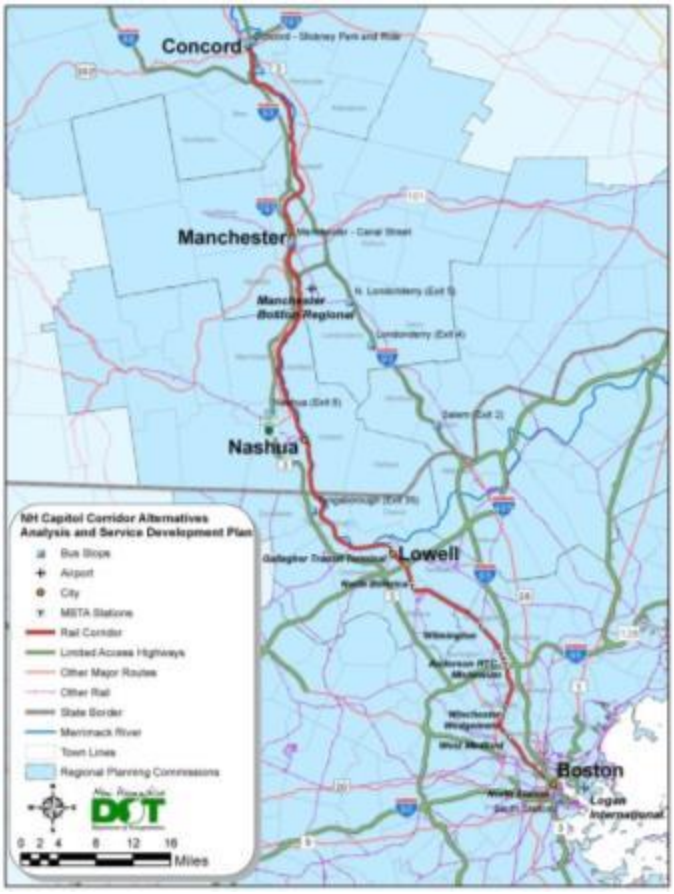
4 Rationale, Goals, and Objectives

The fundamental starting point of any transportation planning effort is to identify the Rationale for improving transportation system service. To meet federal standards, this Rationale conforms to and supports the Purpose and Need Statement as mandated by the NEPA.[2] This Statement defines the public concern that provoked the need to study infrastructure investment in the environmental review process. The definition of the transportation problem considers current and forecasted travel demand and capacity conditions, describes transportation challenges and opportunities faced in markets to be served by the proposed service, and defines the Study's goals and objectives.

4.1 Public Concern/Project Need

The New Hampshire Capitol Corridor AA Study, jointly funded by FRA and FTA, was initiated by the New Hampshire Department of Transportation (NHDOT) in cooperation with the Massachusetts Department of Transportation (MassDOT) to explore and evaluate opportunities to improve public transportation service (intercity rail, commuter rail, express bus) along the 73-mile corridor between Boston, Massachusetts and Concord, New Hampshire (Figure 4.1). The corridor is currently served by express and intercity bus service between New Hampshire and Boston and by commuter rail and express bus service within Massachusetts.

Figure 4.1: New Hampshire Capital Corridor Study Area



The most heavily used transit service in the corridor is the Massachusetts Bay Transportation Authority's (MBTA) commuter rail service, which runs 25 miles between Lowell and Boston and carries more than 17,000 passenger trips each weekday. Permanent passenger rail service has not operated north of Lowell since 1967. A Public Private Partnership, supported by the State of New Hampshire, operates 80 weekday bus trips within the corridor between Manchester, Nashua, and Boston. This service typically carries 1,800 passengers per day. A related private enterprise uses a state-

[2] See Appendix 2 to the Capitol Corridor AA Final Report (Task 2: Project Purpose and Need)

owned terminal to operate intercity bus service between Concord and Boston that carries 150 passengers on typical day. Further south, several publicly operated express bus services link communities up and down the I-93 corridor in Massachusetts with downtown Boston. All together, the Massachusetts bus services carry 2,200 passengers on a typical day.

For purposes of the AA Study, the Capitol Corridor is defined as the area included in the Central New Hampshire Regional Planning Commission (CNHRPC), the Nashua Regional Planning Commission (NRPC), Rockingham Planning Commission, the Southern New Hampshire Planning Commission (SNHPC), the Merrimack Valley Planning Commission (MVPC), the Northern Middlesex Council of Governments (NMCOG), and the Boston Region Metropolitan Planning Organization (MPO).

4.1.1 Study Corridor Dynamics

Metropolitan Boston, like most large American cities, has been continuously extending its reach and geographic scope for decades. With a 20th century highway network and 21st century communication links, the economies of Boston, Nashua, Manchester, and Concord have never been more closely intertwined. Boston's zone of influence first moved beyond I-95/Route 128, then I-495 in Massachusetts, and now clearly extends into southern New Hampshire. It can be expected to continue expanding northward, in addition to westward and southward.

Expansion of the metropolitan area and the Boston commuter-shed has contributed to congestion in the Capitol Corridor, especially near Boston and particularly on I-93. This congestion results partly from the fact that Route 3 loses its freeway functionality south of I-95/Route 128, which negatively impacts traffic flow on the Lowell-Nashua-Manchester side of the corridor.

The congestion resulting from heavy north-south travel along corridor is exacerbated by sprawl-type suburban residential development patterns throughout parts of southern New Hampshire. Sprawl-type development contributes to increased vehicle miles travelled (VMT) throughout the corridor. Denser development patterns do exist within the corridor, particularly in Nashua, Manchester, and Concord.

Business development and job creation in the northern two thirds of the corridor have not kept pace with residential growth, especially in the high-technology sectors that are flourishing in the southern third. This residential/employment disconnect exacerbates transportation issues driving the Capitol Corridor AA Study.

Existing express and intercity bus services are not attractive to an especially broad market and employ a park-and-ride strategy with a focus (mainly) on park-and-ride facilities located at or very near freeway interchanges. This strategy does not promote the dense, sustainable development that leads to reduced VMT.

4.1.2 Project History and Planning Context

Passenger rail service in the corridor started 175 years ago when a train from Boston first pulled into Nashua. Freight service on the line has run continuously since that time. Regular passenger rail service between Concord and Boston ended in 1967, with the exception of a brief restoration of service during a

1980-81 demonstration project. As the region has grown, traffic congestion on the main highway arteries has increased with adverse impacts on travel time and reliability for automobile and bus travel. Consequently, public interest in passenger rail service has grown (as trains are insulated from highway congestion and less likely to impact air quality).

Since the 1980s, numerous studies and plans have supported the return of passenger rail service and expanded transit options in this corridor:

- In 1984, the MBTA and the Boston and Maine Railroad (B&M) studied an extension of commuter rail service to Nashua's newly opened Pheasant Lane Mall. In the early 1990s, NHDOT Commissioner Charles O'Leary and Congressman Dick Swett asked MBTA to consider extending its commuter rail service into Nashua.
- In 2006, the Community Advisory Committee to the NHDOT Commissioner recommended expanded passenger rail as one of the five "initial action items" in its final report, a component of the state's long-range transportation plan.
- In 2007, New Hampshire invested $35 million in new express bus services for travel from greater Manchester and Nashua to Boston. NHDOT has also supported private bus service from Concord to Boston with the purchase of buses and construction of a new bus terminal in Concord.
- In 2007, the New Hampshire legislature created the New Hampshire Rail Transit Authority (NHRTA) with a charge to establish passenger rail service in New Hampshire.
- In 2009, the *New Hampshire Climate Action Plan*, prepared by the New Hampshire Climate Change Policy Task Force, recommended expanded passenger service as part of a balanced transportation system.
- In 2003, the state departments of transportation from New Hampshire, Vermont, and Massachusetts commissioned a feasibility study for the Boston to Montreal rail corridor: *Boston to Montreal High-Speed Rail Planning and Feasibility Study Phase I: Final Report.* The study describes existing conditions, including within the Boston to Concord portion of the Study corridor, and presents a ridership analysis of stations in the corridor. The study found that "further study of associated operational, engineering and cost/revenue factors is warranted."
- In 2004, NHDOT developed a *Lowell, MA to Nashua, NH Commuter Rail Extension Project Environmental Assessment* in anticipation of extending MBTA commuter rail service to New Hampshire.
- The 2010 *New Hampshire Capitol Corridor Project Overview,* a white paper prepared for Amtrak, detailed the corridor's state-of-readiness to function as part of the federal High Speed Intercity Passenger Rail (HSIPR) program.
- Also in 2010, NHRTA commissioned the report *Economic Impact of Passenger Rail Expansion along the New Hampshire Capitol Corridor*. The report assessed the economic impacts of restoring intercity passenger rail service between Boston and Concord. The study supports the case that the implementation of passenger rail along this corridor is a net economic benefit for New Hampshire.

- In 2011, the University of New Hampshire (UNH) Survey Center conducted a poll of New Hampshire residents' attitudes regarding the extension of commuter rail service on the Capital Corridor. It suggested that a majority of residents strongly favored extending commuter service into New Hampshire and a plurality that supported using federal funding to study the issue.
- In 2014, a second poll was conducted that found 68 percent of New Hampshire residents favor the Capitol Corridor project to extend passenger rail service up the Merrimack River valley into New Hampshire. Only seven percent of the statewide sample opposed the service expansion, while 25 percent were undecided or had no opinion.

4.1.3 Population and Employment

While both the New Hampshire and the Massachusetts portions of the corridor are projected to grow over the next two decades (Table 4.1), the Massachusetts portion is projected to grow at a slightly faster pace. It can be anticipated that this population growth will increase demand on the transportation network, which may result in increased levels of congestion and travel times, particularly in corridor's southern portion, which already experiences intense peak-hour highway congestion.

Table 4.1: Historical, Existing, and Forecast Population in the Capitol Corridor Study Area

Geography	1990	2000	2010	2020	2030	2035	Total Change 2010-2035	Percent Change 2010-2035

The nation's largest population group falls between the ages 35 and 64. The fraction of New Hampshire's total population that falls within that age group is higher than Massachusetts, New England, or the nation. The growth of New Hampshire's population over age 65 increased at a significantly faster rate between 2000 and 2011 than in Massachusetts, New England, or U.S.

The median age has increased within the Study corridor, New Hampshire, Massachusetts, New England, and the U.S. The increase in median age has been greatest within the Study corridor (four years), which is more than twice the nationwide increase in median age during the same time period (1.7 years).

Residents of New Hampshire and the Study corridor are older and aging at a faster pace than the surrounding states and the nation. As New Hampshire's residents age, a robust multi-modal transportation network that reduces reliance on single-car ownership will be necessary to support continued mobility and maintain their quality-of-life.

In addition to understanding existing and projected population growth, it is important to ensure that the specific needs of mobility-challenged populations are considered when developing and evaluating transport investment strategies. These households rely on public transportation for local and regional

travel (Table 4.2). Maximizing project benefits to these populations while minimizing adverse impacts is important to the success of expanded public transportation services (rail or bus) in the Capitol Corridor.

Table 4.2: Zero Car Households in the Study Corridor

Employment

Employment levels within the five Study corridor counties are shown in Table 4.3. Employment has generally been growing at one to two percent per year over the last five years.

Table 4.3: Number of Jobs in the Five Counties that the Study Corridor Passes Through (2013 Q2)

Geography	2013 Q2	2012-2013 Change
New Hampshire	602,462	1.1%
Hillsborough County, NH	193,248	1.2%
Merrimack County, NH	75,768	1.0%
Rockingham County, NH	139,900	1.6%
Massachusetts	3,352,700	1.3%
Middlesex County, MA	847,700	1.9%
Suffolk County, MA	608,100	1.7%

Massachusetts Source: Bureau of Labor Statistics, County Employment and Wages in Massachusetts – Second Quarter 2013; http://www.bls.gov/ro1/maqcew.htm

Massachusetts and New Hampshire each forecast industry growth (by the North American Industry Classification System) to 2020. Massachusetts organizes the projections by Workforce Investment Areas (WIAs), while New Hampshire uses the RPC jurisdictions. While the WIA boundaries do not exactly conform to the Capitol Corridor Study area, the Study area generally falls within four WIAs.
Table 4.4 highlights the fastest-growing industries through 2020. The fastest-growing industry in each geography is highlighted in bold font. The fastest growing industries in Massachusetts are – with the exception of construction – service-oriented industries: finance and insurance, professional, scientific and technical services, and other services. New Hampshire's fastest-growing industry – with the exception of professional, scientific, and technical services in NRPC – is health care and social assistance.

These findings reflect New Hampshire's comparatively higher older population and the role of Boston as a regional finance, technology, and business service hub.

Table 4.4: Projected Change in Industry Employment 2010-2020

Households within the Study corridor have a median income over $80,000 per year – greater than median incomes of New Hampshire, Massachusetts, New England, and the nation. This may reflect the fact that the Study corridor includes the most densely developed areas of Massachusetts and New Hampshire (where residents tend to have higher incomes) and excludes the majority of the lower density, rural areas (where residents tend to have lower incomes). Median household income within the Study corridor has risen by two percent (in 2011 constant dollars) between 2000 and 2011, which outperformed New Hampshire, Massachusetts, New England, and the nation.

While the Study corridor fraction of the population living below the poverty line is lower than for all of New Hampshire, all of Massachusetts, or the entire nation, it increased 18 percent increase between 2000 and 2011. As the population living in poverty grows, it will be increasingly important to provide these residents with lower-cost mobility options that reduce the need to own a car.

4.1.4 Existing and Future Land Use

A legacy of New Hampshire's and Massachusetts' colonial and 19th century industrial past is the prevalence of the traditional town-center pattern of development, which was designed to support pedestrian rather than vehicular traffic. This style of development has a comparatively high-density mix of uses in the "downtown" that is easily accessed on foot from the surrounding residential areas. While some infrastructure elements have been retrofitted to facilitate driving, the historic downtown development patterns of Boston, Lowell, Nashua, Manchester, and Concord (and other smaller towns

within the Study corridor) reduce the prioritization of cars and elevate the role of pedestrian and non-motorized modes of transportation.

Another traditional land use pattern, particularly within the New Hampshire portion of the corridor, includes rural, farmland, and open spaces. These land uses, and the environmental assets they preserve, are a critical element of New Hampshire's identity and a major factor in the continued high quality-of-life for New Hampshire residents.

As the population has grown over the decades and development has spread outside of these traditional town-centers, auto-oriented, lower-density residential, and commercial development patterns have emerged. These patterns, which can be found throughout the Study corridor, are typically dominated by the segregation of land uses (as opposed to the mixed use patterns that can be found in the town-center style of development). These separated land uses are connected by comparatively few limited access roadways, which can result in increased levels of traffic congestion during peak travel times.

Both Massachusetts' and New Hampshire's population is projected to grow over the next two decades: According to recent research one-quarter of New Hampshire residents were born in Massachusetts and the population of Massachusetts-born residents is growing faster than the population born in the state.[3] Regardless of the source of the population growth, it will continue to exert increased development pressure on New Hampshire's communities. In the absence of a strategic land use framework, this pressure could result in increased levels of congestion, encroachment into open spaces, and a reduced quality-of-life.

Communities throughout New Hampshire and Massachusetts, including those within the Study corridor, have recognized the potential costs associated with policy and regulatory inaction, and have undertaken numerous land use and development planning activities designed to encourage more sustainable land use patterns.

4.1.5 Economic Development and Land Use

Access to Boston-based Employment

Public transportation investment along the Capitol Corridor will improve multi-modal connectivity between New Hampshire's residents and Boston, the region's major employment center. Expanded access to Massachusetts' diversified employment base will benefit existing New Hampshire residents, and may encourage them to stay in their current communities rather than move closer to Boston.

[3] Kenneth M. Johnson; Many New Voters Make the Granite State One to Watch in November; Carsey Institute; http://cola.unh.edu/sites/cola.unh.edu/files/research_publications/IB-NHVoter08.pdf

Business Attraction in New Hampshire

In addition to improved access to Boston's employment market, public transport investment in the corridor may be leveraged to lure businesses into New Hampshire. Millennials – the 18- to 34-year-olds that rival the Baby Boomers in size and cultural influence – have repeatedly stated a preference for built environments that support a car-light or car-free urban-style existence. These Millennials are the rising "creative class" – workers whose career orientation is towards ideas and innovation rather than heavy manufacturing and assembly lines. As businesses – particularly technology-oriented businesses – look for lower-cost alternatives to downtown Boston and more Millennial-friendly environments than the Route 128 corridor, Capitol Corridor communities can increase their attractiveness by investing in non-automotive transport. Improved connectivity will not only improve access to Boston-based employment, but can draw these "creative class" workers (and the companies that want to hire them) into the New Hampshire portion of the Capitol Corridor.

More Strategic and Sustainable Land Use Patterns

Access to the Boston employment market and the attraction of businesses into New Hampshire both rely on the efficient flow of people between their homes and places of employment. Regardless of any transport investment, travel in the corridor is anticipated to increase. In the absence of transportation network investment, this growth in travel will lead to increased levels of congestion and decreased levels of mobility. Simply expanding the roadway network is not a solution to this problem as it would likely induce additional demand that, in turn, would further exacerbate congestion.

While mobility problems are most directly solved by transportation investment, land use patterns play a critical role in supporting the efficient movement of people and goods. In addition to using public transportation investment to expand transportation network capacity, strategic land use planning that focuses higher-density, mixed use development near public transportation stations can reduce demand on the transportation network by supporting trip efficiencies. This land use pattern would reflect a return to the traditional New England "town-center" development style.

More efficient land use patterns can also encourage the expansion of employment opportunities closer to home, resulting in shorter travel distances. This would reduce demand on the transportation network, which would reduce overall travel times and congestion.

Sustainability and Quality-of-Life

A sustainable transportation system is one that meets and balances existing community environmental, social, and economic needs without compromising resources for future generations.

Environmental

A portion of the New Hampshire character is rooted in the state's natural beauty, including its mountain ranges, chains of lakes, sea coast, and protected forest land. The environmental impacts of increased levels of development and corresponding growth in transportation network demand may negatively impact these environmental assets unless proactive investments in sustainable infrastructure are pursued.

New Hampshire's Energy, Environmental, and Economic Development Benchmark Report,[4] released by the New Hampshire Energy and Climate Collaborative in 2012, reports that transportation accounts for 35 percent of the New Hampshire's energy use and 46 percent of the its greenhouse gas (GHG) emissions. Total transportation-related energy consumed and GHG emission rates have remained flat in recent years, even though VMT and per capita VMT have decreased approximately five percent between the peak in 2006 and the most recent data in 2009. At the same time, public transport use has increased 25 percent between 2000 and 2010.

Because the Capitol Corridor is home to the three largest cities in the state (Concord, Manchester, and Nashua) as well as two major north-south arteries (Route 3 and I-93), transportation network investments that support mode shift away from automobiles are likely to support a decrease in per capita VMT and may support reductions in GHG emissions.

Economic

The New Hampshire Center for Public Policy Studies' *From Tailwind to Headwind: New Hampshire's Shifting Economic Trends,*[5] published in 2012, found that state demographic trends are related to economic trends. The state's economic advantage has traditionally been rooted in three areas: consistent population growth, increased productivity, and a more resilient economy than its competitors. However, data shows that population growth is slowing, labor force participation is declining (due to an aging population), and the rate of growth in educational attainment is slowing.

Like the Baby Boomer generation before them, the sheer size of the Millennial generation, those born between approximately 1982 and 2003, means their preferences will shape every aspect of the country's economy and culture in the coming decades. Communities that invest in infrastructure and make policy decisions attractive to this generation will be successful in creating an economic framework for sustainable growth. This is particularly important for New Hampshire, which is aging at a higher-than-average rate. A 2013 report by U.S. Public Interest Research Group, *A New Direction: Our Changing Relationship with Driving and the Implications for America's Future,*[6] came to three conclusions:

- Young people aged 16 to 34 drove 23 percent fewer miles on average in 2009 than they did in 2001 – a greater decline in driving than any other age group. The severe economic recession was likely responsible for some of the decline, but not all.
- Millennials are more likely to want to live in urban and walkable neighborhoods and are more open to non-driving forms of transportation than older Americans.

[4] http://www.unh.edu/news/releases/2012/jun/ds28climate.cfm
[5] http://www.nhpolicy.org/UploadedFiles/Reports/New_Hampshire_New_Reality_2012_final1.pdf
[6] http://www.uspirg.org/sites/pirg/files/reports/ANewDirectionvUS.pdf

- If the Millennial-led decline in per capita driving continues for another dozen years, even at half the annual rate of the 2001-2009 period, total vehicle travel in the U.S. could remain well below its 2007 peak through at least 2040 – despite a 21 percent increase in population.

The Capitol Corridor is home to one of the largest private employers in the state (BAE Systems) and the state's largest labor pool. Public transport investment within this corridor will provide a lower-cost commuting alternative that links New Hampshire residents with employment opportunities while increasing New Hampshire's attractiveness as a place to do business.

Social

In his 2012 report *New Hampshire Demographic Trends in the Twenty-First Century,*[7] Kenneth Johnson of the Carsey Institute at the UNH documents several trends that can be extracted from the most recent census data:

- New Hampshire's population increase is slowing, New Hampshire's population is aging, the pace of demographic change is uneven in the state, and the state is becoming more diverse.
- Young adults are migrating to metropolitan cores, family age residents are migrating to suburbs, major metropolitan cores are losing older residents, and rural counties are losing young adults.
- Many towns in the Capitol Corridor, including Manchester and Nashua, have the largest concentrations for young persons (less than 18) in the state.

Quality-of-Life

Granite State Future is a statewide project coordinating development of regional plans in each of the RPC's jurisdictions. It recognizes the interconnection between development patterns, availability of housing choices, and diversity of transportation choices as a means to preserve natural resources and community vitality and promote energy efficiency. Public transportation investment within the Capitol Corridor would be a powerful investment that can be leveraged to implement this regional, multi-discipline vision to maintain New Hampshire's high quality-of-life.

4.1.6 Project Need Summary

Capitol Corridor dynamics (i.e., population expansion, employment conditions, existing/future land use, and economic development and land use) have contributed to the need for improved public transportation service, as summed below.

[7] http://gencourt.state.nh.us/house/committees/committee_websites/waysmeans/DOI2013/Report-Johnson-Demographic-Trends-NH-21st-Century.pdf

Projected population growth will result in increased roadway congestion. As population density increases over the coming years, an increased number of multi-modal transportation options to Boston, the region's largest employment center, will be critical to mitigate corresponding increases in roadway congestion, particularly along I-93 and Route 3.

New Hampshire's existing transportation network does not effectively connect existing modes. Increased levels of corridor transit investment will improve local and regional mobility by linking travelers to the network of existing transportation modes: roadway, buses, commuter rail, heavy rail, light rail, bicycles, ferries, and airplanes. These increased linkages will improve ridership and usage across all modes, while promoting sustainable mobility.

The regional economy suffers from singular dependency on roads for movement of goods and passengers. Investing in transportation infrastructure that provides an alternative to roadway transport will link New Hampshire's businesses, industries, and residents to the national and New England transportation network.

Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents. A mismatch between locations of residence and employment forces many in New Hampshire to spend comparatively long periods of time commuting to work. Investing in more efficient transportation modes will not only improve connectivity between existing centers of residence and employment, but increased levels of multi-modal access may also catalyze additional business investment within New Hampshire.

New Hampshire is experiencing a young professional "brain drain." While the region's overall population is projected to grow in the coming decades, young professionals are choosing to leave southern New Hampshire to be closer to the employment and cultural and social opportunities associated with larger urban centers. Improved transit connectivity will support the attraction and retention of young professionals within the Capitol Corridor Study area.

New Hampshire is getting older. New Hampshire's senior population continues to grow. Additional shared transportation accommodations that support "car-light" mobility will be required to accommodate these emerging demographic and lifestyle trends, and will continue to make New Hampshire attractive to residents from childhood through retirement.

Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life. Population growth, if not guided through strategic infrastructure investments that promote efficiency, will result in uncoordinated development patterns and sprawl, diminishing the region's high quality-of-life and negatively impacting its unique character.

The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences. Expanding existing roadways and constructing new roadways will not be sufficient to sustainably accommodate the projected growth in travel demand, causing negative environmental consequences associated with an increased number of VMT and corresponding congestion.

4.2 Defining the Transportation Problem

4.2.1 Transportation Facilities and Services – Travel Demand and Capacity

The Capitol Corridor's robust transportation network includes roadways, highways, transit services, intercity passenger rail service, freight railroads, airport, and pedestrian and cyclist facilities. Despite the dense, multi-modal nature of this transportation network, peak highway demand outweighs available capacity and opportunities exist to improve connectivity between the current modes.

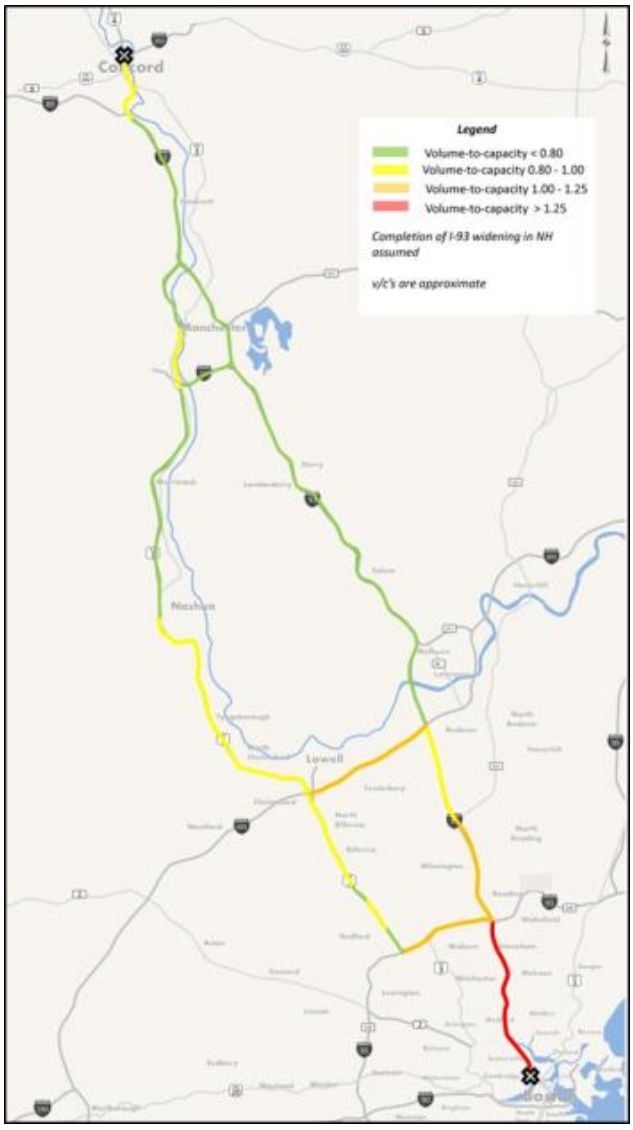
Highway Facilities

The limited access highways that connect New Hampshire's major population centers to metropolitan Boston – I-93, US Route 3/Everett Turnpike, I-95/Route 128, I-293, and, I-495 – cover 134 miles of limited access freeway facilities and interchanges, shared between the States of New Hampshire and Massachusetts. The breakdown on the corridor mileage is as follows:

- I-93: 65 miles
- US Route 3: 49 miles
- I-95/Route 128: 11 miles
- I-293: 11 miles
- I-495: 9 miles

The corridor has experienced rapid population growth, and many of the new residents commute to jobs in greater Boston. New Hampshire and Massachusetts expanded the highway system to accommodate increasing traffic, but the prospects for additional expansion are unlikely due to financial and environmental constraints. At a minimum, the advent of passenger rail service may delay the need for further highway widening. Traffic volume at the state line on US Route 3/Everett Turnpike in Nashua grew by nearly 26 percent from 2002 to 2009, to 88,200 (average daily traffic), and projections are for continued traffic growth in the corridor in both states. More detail on existing highway conditions is provided in *Section 5: Existing Corridor Conditions*; Figure 4.2 shows current morning peak highway volume-to-capacity ratios (more detailed information is provided in *Section 5: Existing Corridor Conditions*, *Highway Level of Service*).

Figure 4.2: Current Morning Peak Highway Volume-to-Capacity Ratios



Public Transportation Services and Facilities

The Capitol Corridor has a variety of commuter and local bus operators, as well as MBTA commuter rail service and Amtrak intercity passenger rail service on the *Downeaster* line.

Regional and Local Bus Service

Seven regional and four local bus operators provide service within New Hampshire and intercity service to Boston and beyond. Boston Express (BX) provides the primary commuter service within the Study area along the heavily congested Massachusetts segments of I-93. Existing traffic congestion along I-93 and Route 3 significantly impact scheduled travel times for express and intercity bus services. For instance, BX's 6:30am southbound departure from Londonderry (Exit 4) on the I-93 service is scheduled for a one-hour trip to Boston South Station. Meanwhile, the 9:50am southbound departure is scheduled for a two-hour and 20 minute trip, which is a built-in or induced delay of one hour, 20 minutes. More detail on existing bus services (Base) is provided in *Section 5: Existing Corridor Conditions*.

MBTA Commuter Rail Service

On a typical weekday in 2014, Lowell was served by 44 MBTA revenue trains to and from Boston's North Station. The 25-mile trip serving up to seven intermediate station stops takes 44 to 49 minutes. Six weekday non-revenue "deadhead" trains run between Lowell and Boston to stage the service because there is no facility for the overnight storage or maintenance of the trains in Lowell. Typical weekday MBTA ridership on the entire line is 17,500 passenger trips, including both northbound and southbound travel. Lowell is the busiest station on the line with 4,280 weekday boardings and alightings. The running time between Lowell and Boston ranges between 45 and 49 minutes with a maximum allowable speed of 70 mph. The daily schedule includes approximately 150 daily deadhead train miles. More detail on existing commuter rail service is provided in *Chapter 5: Existing Corridor Conditions*.

Amtrak *Downeaster* Service

Intercity passenger rail service between Boston and Portland was restored in 2001 after an absence of more than 35 years. The *Downeaster* service features five daily round trips between Portland and Boston North Station, with eight intermediate stops – Woburn, Haverhill, Exeter, Durham-UNH, Dover, Wells, Saco, and, in season, Old Orchard Beach. On November 1, 2012, two daily *Downeaster* trains were extended to Freeport and Brunswick, Maine. Ridership on the *Downeaster* service in FY2013 was nearly 560,000 passengers, up 3.4 percent from the year before. Most trains make the Boston-Portland trip in two hours, 30 minutes.[8] More detail on existing intercity passenger rail service is provided in *Section 5: Existing Corridor Conditions*.

[8] Amtrak Fact Sheet, Fiscal Year 2013, State of New Hampshire

Freight Railroad Service and Facilities

The New Hampshire Main Line (NHML) was, and remains, a principal artery of the B&M network and a key economic link between the Granite State and the national economy. Since the 1980s, the B&M has belonged to a regional amalgam of railroads initially called the Guilford Rail System, later changing its name to PAR. Headquartered in Billerica, Massachusetts, PAR owns and operates the former B&M and Maine Central Railroads as an integrated system, roughly running from Bangor to Albany with numerous branches in New Hampshire and other New England states. North of Chelmsford, PAR refers to the route as its "Northern Branch." More detail on existing rail freight rail service is provided in *Section 5: Existing Corridor Conditions*.

Air Travel

Expanded public transportation in the corridor could create an additional connection between the Manchester-Boston Regional Airport (Manchester Airport or MHT) and Boston – a system in which the three principal Boston-area airports are connected by rail (with the MBTA Blue Line connection at Boston-Logan Airport and the MBTA commuter rail connection to Providence's TF Green Airport). Manchester Airport is an important economic engine for New Hampshire and the region, creating jobs, facilitating commerce, and providing access to the global marketplace. Manchester Airport contributes over $1 billion annually to the region's economy and accounts for more than 3,500 jobs in the three-county region contiguous to the airport. A connection to the airport through an intermodal station adjacent to the airport access highway would create new rail-air connectivity.

Manchester Airport strongly supports the development of passenger rail service in New Hampshire as part of a multi-modal solution to meet the growing and changing transportation needs of the region. The airport incorporated a review of passenger rail service (and an anticipated airport rail station) as a focus of its 2011 *Master Plan Update* and determined that there are important synergies between passenger rail and air passenger transportation systems. Manchester Airport will benefit from both rail ridership by enplaning passengers (air travelers originating from the area and using passenger rail service to travel to the airport from their home or business) and deplaning passengers (air travelers accessing New England through Manchester Airport and using passenger rail service to travel from the airport to their final destination).

4.2.2 Travel Patterns and Market Analysis

Market analysis provides a critical first step to estimate travel demand in the Capitol Corridor. The market analysis provides "big-picture" travel flows in the Study area and identifies their relationship to the corridor by quantifying the total size of the travel market and key origin-destination travel patterns.

The geographic area of the Capitol Corridor travel market is defined by the existing track alignment along the banks of the Merrimack River extending north from Lowell through the proposed station locations of Nashua and Manchester, and ending in Concord. This corresponds roughly with the US Route 3 corridor in New Hampshire. The full length of the corridor varies by alternative, but, at its maximum, generally runs from Concord's intercity bus terminal adjacent to the rail corridor in the north,

to Boston's North Station in the south. This section focuses on the New Hampshire market[9] in the proposed Study area, considering three main work and business travel markets:

- New Hampshire to Massachusetts
- New Hampshire to New Hampshire
- Massachusetts to New Hampshire

Mobility of individuals and their ability to reach places of employment, particularly to locations outside their areas of residence, is highly dependent on the availability of an automobile. Workers without an automobile, or access to one, are transit-dependent if they live outside walking or biking distance of their jobs.

Corridor population[10] within the proposed service catchment area is an important indicator of the potential use of transportation infrastructure and services. The corridor connects the three largest cities in New Hampshire: Concord, Manchester, and Nashua. These cities, as well as the other communities on the corridor, represent nearly 39 percent of the population and just over 41 percent of employment in the entire State of New Hampshire. Concord, Manchester, and Nashua alone account for 24 percent of the population and just over 27 percent of the employment in the state.

- **New Hampshire-to-Massachusetts Work-Trip Market:** The New Hampshire communities within the corridor generate approximately 200,000 work trips, of which over 28,000 (14 percent) are destined for locations in eastern Massachusetts. Of these 28,000 trips, approximately 10,000 (35 percent) are destined to locations along the existing MBTA Lowell commuter rail line. These trips are the main component of the New Hampshire-to-Massachusetts work-trip market that would be served by the Capitol Corridor.
- The main destinations of the New Hampshire work trips are Lowell and Boston/Cambridge. Lowell attracts just over 2,000 work trips from the corridor communities and Boston/Cambridge attracts just over 4,000. The Boston/Cambridge trips face severe congestion during work commuting times and are considered a very strong market for the Capitol Corridor service.
- **New Hampshire-to-New Hampshire Work-Trip Market:** Of the approximately 200,000 work trips generated by the New Hampshire corridor communities, just over 170,000 remain in New Hampshire and a large majority of these nearly 148,000 stay within the corridor itself. Not all of these trips are part of the market that the Capitol Corridor project would serve, but they do show the relatively large number of work trips within New Hampshire.

[9] The New Hampshire market is considered to be communities along the corridor and consists of Concord, Manchester, Nashua, as well as Bow, Pembroke, Hooksett, Goffstown, Bedford, Londonderry, Merrimack, Litchfield, and Hudson

[10] Population, employment, and commuting to work numbers are from the U.S. Census Bureau, 2006-2010 American Community Survey five-year estimates

The intra-New Hampshire market consists primarily of the work trips among the major cities of Concord, Manchester, and Nashua. Excluding intracity trips, the work-trip market between these cities approaches 10,000 trips each weekday.

- **Massachusetts-to-New Hampshire Work-Trip Market:** This market is the smallest of the three major work-trip markets, with a total of 1,370 work trips from the Massachusetts communities in the corridor to the cities of Concord, Manchester, or Nashua. The majority of these trips are from the cities of Lowell (773) and Boston (300). Similar to the trips from New Hampshire to Boston, the trips from Boston face the severe congestion during peak commuting hours.

4.3 Goals and Objectives

A set of goals and objectives (Table 4.5) were developed to determine how well a public transportation (intercity rail, commuter rail, or express bus) investment along the Capitol Corridor will address regional and corridor needs and build on current and recent planning. Research and analysis to date demonstrates that integrated transportation and land use planning can play a positive role in supporting an economically, environmentally, and socially sustainable community. A major public transportation investment would be a significant step in implementing this integrated planning approach within the Capitol Corridor.

Table 4.5: Capitol Corridor AA Study Goals and Objectives

Goals	Objectives
Transportation and Mobility Leverage the existing transportation network to improve access and mobility within the corridor and throughout the region	▪ Provide alternatives to address congestion within the Study corridor ▪ Expand the transit network capacity ▪ Increase transit ridership and mode share by expanding the existing rider base and attracting choice riders ▪ Provide travel time savings ▪ Improve the efficiency, convenience, and reliability of transit service
System Integration Invest in transportation improvements that complement the existing multi-modal transportation network	▪ Increase corridor modal connectivity ▪ Provide connections to other corridors within the region ▪ Increase access to the Manchester Airport through additional transit service ▪ Balance system capacity (MBTA, BX, Concord Coach) ▪ Ensure operating efficiency
Economic Development and Land Use Support the vision for growth laid out in local/regional development plans	▪ Improve access to higher-paying jobs in greater Boston ▪ Support development patterns/lifestyle choices that attract younger, highly educated professionals to New Hampshire ▪ Leverage younger, highly educated employee base to attract new businesses/grow existing ones ▪ Promote Transit-Oriented Development (TOD) to mitigate sprawl development patterns ▪ Improve the potential for additional freight rail business through infrastructure upgrades
Sustainability Support transportation investments that contribute to an environmentally, economically, and socially sustainable community	▪ Leverage existing transportation infrastructure to qualify for federal transportation investment dollars ▪ Mitigate potential adverse environmental impacts resulting from anticipated development ▪ Support growth patterns that attract and retain residents from childhood through retirement ▪ Improve access to other tourism, recreation, and cultural attractions in greater Boston and New Hampshire

5 Existing Corridor Conditions

5.1 Railway Facilities and Services

The first passenger train in New Hampshire arrived in Nashua from Lowell, Massachusetts in October 1838.[11] Passenger rail service along this alignment was soon extended to Manchester and Concord with further extensions into the White Mountains and westerly to Hanover and White River Junction. The NHML was, and remains, a principal artery of the B&M network. Consequently, the line functions as a key economic link between the Granite State and the national economy. NHML passenger service ran for almost 130 years until it was abandoned in 1967. Passenger service was briefly restored in 1980, but abandoned again when federal funding expired. Freight service has been operated continuously for 175 years.

Based on a review of 20th century passenger timetables, the fastest trips between Boston and Concord were offered in the 1950s when the new light and self-propelled Budd RDC (Rail Diesel Cars) made the 73-mile trip in as little as 82 minutes. During the steam age, in the first half of the century, the shortest travel times were 120 minutes for the same destination pair.

In the first quarter of the 20th century, 29 passenger stations existed between Boston and Concord (see Table 5.1). With the rise of the highway network, that number was gradually reduced to 16 in 1945.

Table 5.1: Passenger Service Summary 1910-1954

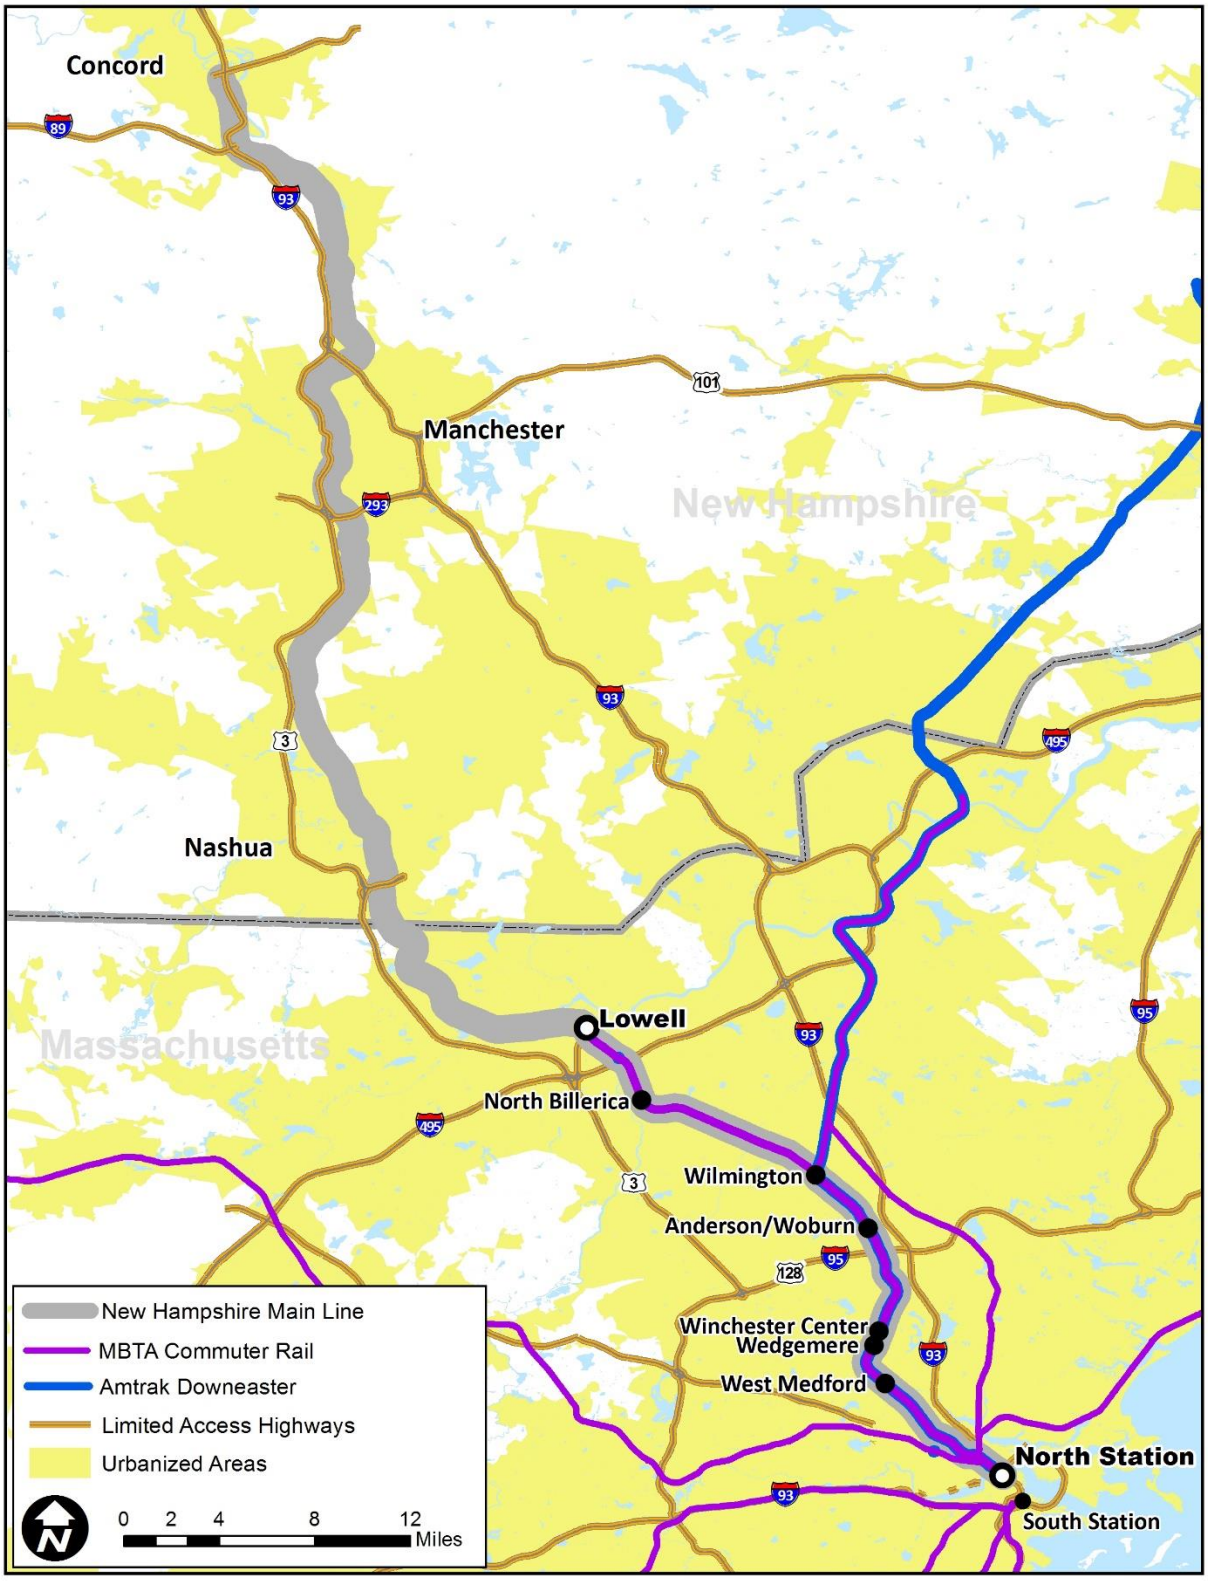
Year	Number of Stations	Nashua Trains	Manchester Trains	Concord Trains
1910	29	30	28	28
1926	29	26	24	24
1945	16	18	17	17
1954	16	19	22	21

Source: Jacobs' analysis of historic public timetables

The numbers of weekday passenger trains serving the line also declined from a high of 30 in 1910 to a low of 18 in 1945. In 1954, with the introduction of new Budd RDC cars and post-war prosperity, the B&M slightly expanded the frequency of passenger trains along the line. However, by the late 1960s, the passenger service was no longer profitable and was discontinued due to the growth of the interstate highway system. Existing passenger rail service is shown in Figure 5.1.

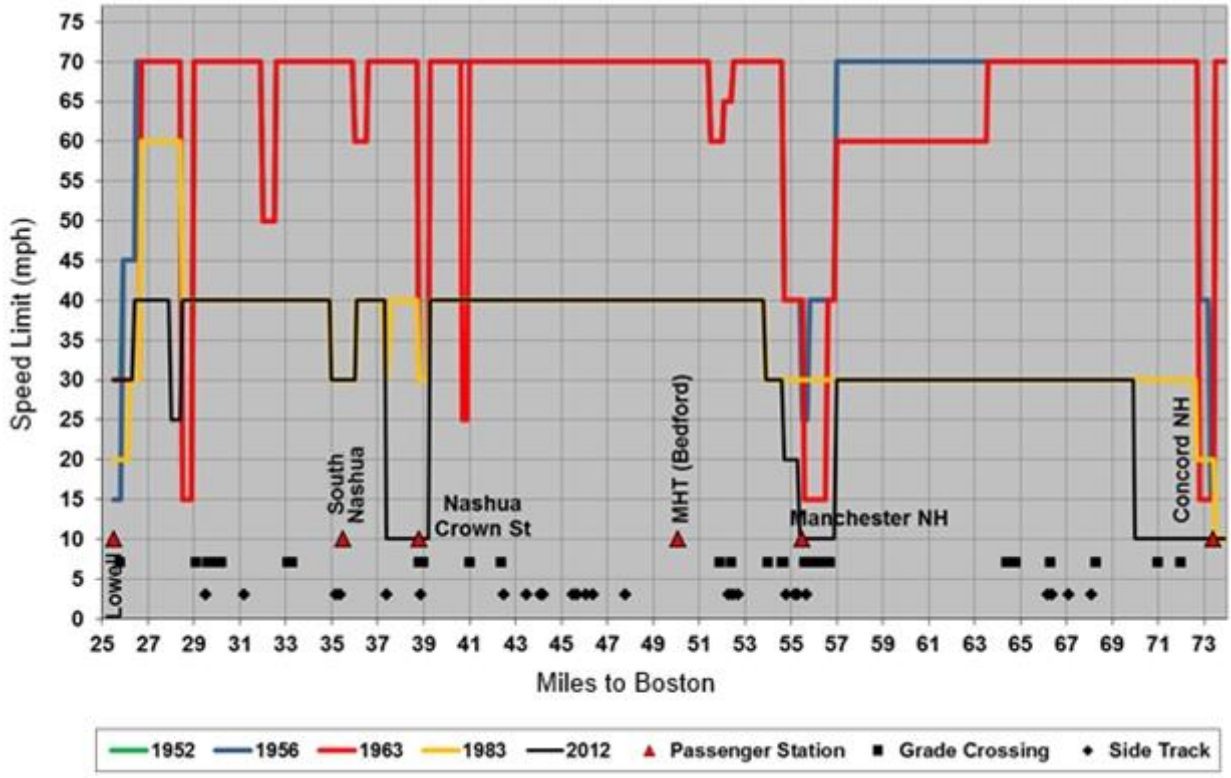
[11] New Hampshire Department of Transportation, *New Hampshire State Rail Plan 2012*, p. 21

Figure 5.1: Existing Passenger Rail Services



A review of B&M employee timetables showing speed limits for the line during the 1950s and 1960s indicated that the maximum allowable speed along most of the line between Lowell and Concord was 70 miles per hour (mph) with numerous speed restrictions for curves, densely settled urban areas with a high-density of grade crossings and railway yards (see Figure 5.2).

Figure 5.2: Historic and Existing Speed Profiles for NHML from Lowell, MA to Concord, NH



When passenger service was abandoned due to declining ridership in the late 1960s, the B&M stopped maintaining the line for passenger speeds and lowered the maximum allowable speeds to 40 mph south of Manchester and 30 mph north to Concord. Currently, the short segment between Lowell and Chelmsford is part of the B&M's existing freight main line and is still operated and maintained at a 60 mph freight standard. The maximum allowable passenger speeds between Lowell and Boston are between 60 and 70 mph.

5.1.1 Track Configuration

Once a busy main line railway, the NHML was double tracked to Concord and beyond. However, today the railway is largely single tracked north of Chelmsford with some passing sidings, yards in Nashua and Manchester, and numerous turnouts to customer sidings.[12] A track configuration chart for the segment north of Lowell can be found in Figure 10.1. The 48-mile segment between Lowell and Concord has 26 switches off the main line to yards, customers, sidings, and branches. The most notable freight customers along the line are Public Service of New Hampshire (PSNH), Quebec Cement, Anheuser Busch, and Nashua Corporation. The PSNH power plant in Bow regularly receives unit trains of coal (approximately 100 annually) and is by far the state's largest volume receiver of rail freight. This may change in the future as PSNH considers a potential future conversion to natural gas turbines.

The NHML has two active branches:

- The Hillsboro Branch leads west from Nashua approximately 30 miles to Bennington, New Hampshire. The eastern most 12 miles to Wilton are owned and operated by PAR. The 18 miles between Wilton and Bennington are owned by the State of New Hampshire and operated by the Milford-Bennington Railroad.
- New England Southern Railroad (NEGS) operates north from Concord using 18 miles of the state-owned line that runs north from Concord toward Lincoln.

5.1.2 Ownership

In Massachusetts, the southernmost 34.5 miles of the line were acquired by MBTA in the 1960s. At that time MBTA acquired most of the main line assets of B&M and the New Haven Railroads in eastern Massachusetts. Today, the southernmost 25.4 miles of the route between Boston and Lowell are busy with passenger traffic operated by the MBTA and Amtrak, and some local freight services operated by PAR.

In New Hampshire, the NHML is property of PAR. In 2011, PAR conveyed trackage rights to MBTA to operate passenger trains on the NHML northward into New Hampshire between the state line and Concord.

5.1.3 Railway Signal System and Traffic Regulation

The train control signal system for the route supports Northeast Operating Rules Advisory Committee (NORAC) Rule 261 between North Station and Manchester. Rule 261 allows for bi-directional operation with automatic wayside block signals on all main line tracks. North of Manchester, there are no wayside signals and operations are governed by Data Communication System (DCS) rules, wherein a Form D train order issued over the radio by the railroad dispatcher in Billerica, Massachusetts is necessary to move a train.

[12] The line is double-tracked for the 25 miles between Boston's North Station and the Gallagher Intermodal Terminal in Lowell

5.1.4 Track Conditions and Potential for Upgrades

Inspection of MBTA and PAR timetables and track charts coupled with a hi-rail inspection trips in April and June 2014 between Lowell, Massachusetts and Concord, New Hampshire provided the following information concerning track conditions.

Railway track is the structure consisting of rails, fasteners, tie plates, ties, and stone ballast that guides and supports the train as it moves down the railroad. More than 150 years of development has led to near universal standards for track design, but marginal innovations are made every few years. The predominant track form worldwide consists of flat-bottom steel rails that support and guide rail vehicle wheels. The rails are seated on steel plates fastened to and supported by timber ties. The ties are laid in a bed of crushed stone, also known as ballast.

For generations, rails were laid in 39-foot sections tied together with joint bars and bolts. The joints in the rail are a weak point in the track structure, subject to substantial maintenance to provide a smooth route for the vehicle wheels. Loose and damaged joints diminish ride quality, tie life, and maximum allowable speeds. Beginning in the 1950s, U.S. railroads started welding their rails into long continuous ribbons that significantly improved ride quality and eliminated most maintenance associated with joints. The conversion to welded rail has been a long process. Today, most heavily trafficked and higher-speed railways use track constructed with continuously welded rails fastened to the ties with an array of resilient, elastic steel fasteners that further reduce maintenance and improve ride quality. Routes with less traffic have generally not been updated with welded rail or the newer fastening devices.

In recent decades, the U.S. rail industry has been using heavier rail for main line track construction. Heavier rail can support greater axle loads and higher train speeds with less stress, damage, and resulting maintenance compared to lighter rail. Rail weight is graded in pounds per yard. For most new construction, MBTA and Amtrak use rail in the range of 132 to 136 pounds/yard, but substantial portions of both networks use rail in range of 112 to 115 pounds/yard. For instance, most of Amtrak's *Downeaster* route between Boston and Brunswick runs on 115-pound rail. PAR's main line is built with 100, 112, and 115 pounds rail.

The traditional rule of thumb for track life has been that timber ties should be replaced after 20 years and rail should be expected to last 50 years. MBTA has had several bad experiences with concrete ties and is not installing them on their commuter rail road. With the materials technology and manufacturing advances of the second half of the 20th century, both rail and ties are showing longer lifecycles, but there is considerable variability in longevity. Depending on a variety of circumstances, some timber ties last as long as 40 years, while other ties fail in as little as four years after installation. Heavier traffic tends to reduce track life. Moisture from poor drainage and weak ballast support also tends to hasten wooden ties' deterioration.

- **Inspections**: U.S. railway track used for passenger operations is subject to two inspections per week that visually check for track defects and obstructions. The most common defects are loose or missing fasteners that are fixed by the inspection patrol, as discovered. In addition to frequent inspections, a program of renewal and replacement is required to keep the track up to the desired FRA standard.

- **Ballast**: Once installed, operating track is maintained by periodically renewing (supplementing) the ballast while refining any deviation in the grade and cross level of track.
- **Ties**: There are typically 24 ties per 39-foot section of rail. Only eight to 10 of those ties need to be in good condition to support 60 mph passenger trains. The remainder can be allowed to deteriorate. To maintain a constant distribution of good ties in the track structure, the ties are periodically renewed to replace the worst with new ties.
- **Rail**: Rail is regularly ground to keep the surface smooth and in good condition. The rail is also subject to regular ultrasonic inspection to find hidden defects in the steel. Where the rail is jointed, defective rails are cutout and replaced. The mechanism for replacing a bad spot in a string of welded rail requires cutting to remove the bad spot and welding in a plug rail to replace it. Wholesale rail replacement programs are infrequent, unless anticipated changes to traffic on the line require greater strength or higher allowable speeds.

5.1.5 Track Class and Maximum Speeds

Standards for track maintenance and maximum speeds are set by FRA. Tracks maintained to a higher standard are allowed to operate at a higher speed. Passenger train speeds generally range between 60 mph for FRA Track Class 3 up to the Class 7 maximum speed of 125 mph (see Table 5.2). Currently, the Northeast Corridor between Boston and Washington is the only route in the U.S. that permits speeds in excess of 125 mph.[13,14] Most passenger routes and main line freight routes are maintained to FRA Class 3 or 4. Branch lines and other lightly used routes are maintained to FRA Class 2 or 1.

Table 5.2: FRA Track Class and Maximum Allowable Speeds (mph)

Track Class	Freight Trains	Passenger Trains
Excepted	10	N/A
1	10	15
2	25	30
3	40	60
4	60	80
5	80	90
6	110	
7	125	
8	160	
9	200

5.1.6 Current Track Class and Speeds

Within the southern 25 miles of the NHML between Boston and Lowell, MBTA currently operates daily commuter rail service, independent of most freight operations, with some segments maintained to a 70 mph speed standard. Most trackage is rated for 60 mph passenger operations. It is presumed that any future passenger rail trains operating within this section of commuter rail territory would use existing track and be restricted to the current timetable speeds.

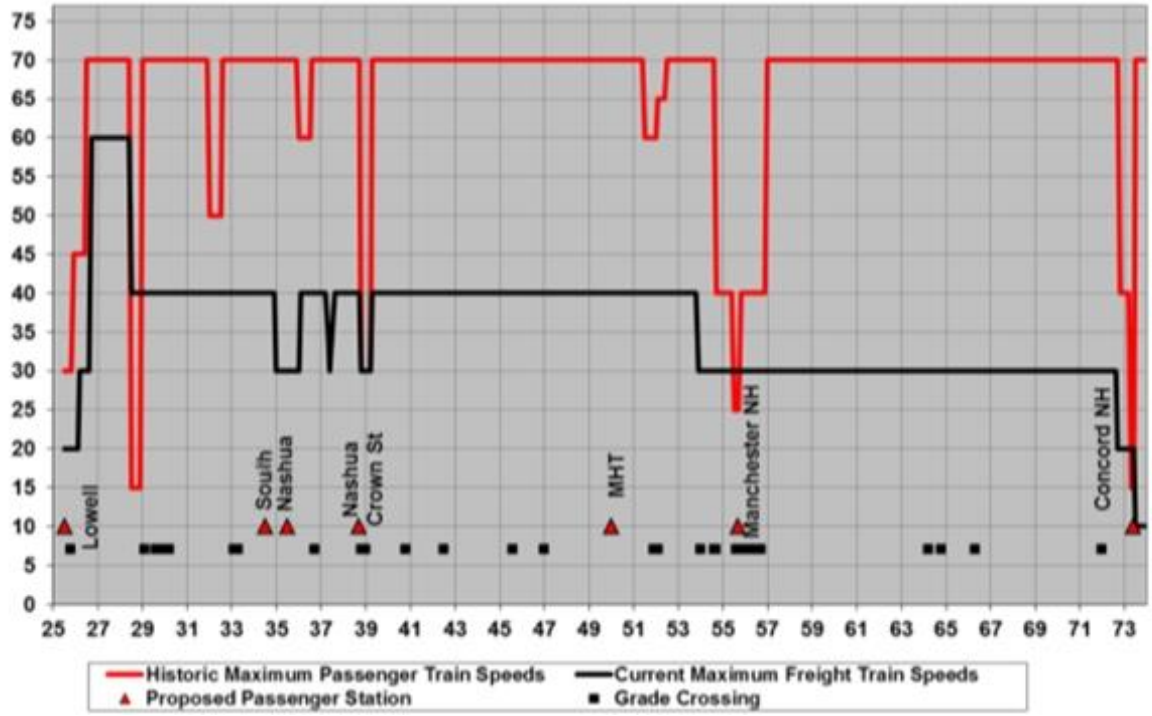
Existing rail traffic north of Lowell consists solely of freight movements with varying levels of train volume depending on the location. The greatest traffic is on the southern portion of the route between Lowell and North Chelmsford, Massachusetts. Traffic density between North Chelmsford and Concord, New Hampshire decreases as the route extends north of the New Hampshire state line into Nashua, Manchester, Bow, and Concord with typically no more than two train movements per day north of Bow.

North from Lowell is a three-mile section of track to North Chelmsford that experiences heavy freight traffic. This segment of PAR's east-west main line is maintained for a maximum freight speed of 40 mph (Class 3).

At North Chelmsford the line splits at a wye. The western leg is PAR's east-west main line and the northern leg is the lesser-traveled NHML. The NHML line runs northerly another seven miles to the New Hampshire state line where right-of-way and track ownership changes from MBTA to PAR.

PAR's ownership continues 39 miles to the north through the cities of Nashua, Manchester, and Concord with mostly 40 and 30 mph freight speeds on predominately Class 3 track north to Bow with Class 2 track north to Concord. Figure 5.3 shows the historic passenger train speeds and the current freight train speeds between Lowell and Concord.

Figure 5.3: Historic Passenger Speeds and Current Freight Speed for NHML from Lowell, MA to Concord, NH



5.1.7 Track Conditions

The track conditions along the route are consistent with the assigned FRA Track Class and maximum speeds. Over the 25 miles where MBTA operates its Lowell commuter rail service, all rail is welded with the latest major tie renewal completed in 1992. The oldest rail on this segment was manufactured in 1980. Much of the track uses 132-pound rail, but approximately 20 of the 51 track miles between Boston and Lowell uses 115-pound rail.

The character of the PAR main line between mile post (MP) 25.5 and MP 28.5 varies radically from the MBTA service segment. The track is jointed here, and the northbound track is primarily constructed with 100 pound rail manufactured in 1927. The southbound track is mostly constructed with 112-pound relay rail from 1965. Relay rail is rail that had been previously used at a different location where it was removed and reinstalled at its present location. Field inspection indicates that tie conditions along this segment are commensurate with the track class (e.g., at least 10 out of every 24 ties are in good condition).

Traffic density and composition on the line changes north of the wye at North Chelmsford. Fewer trains are operated, but one of the regular trains is a long (approximately 90 car), heavy (over 10,000 tons) coal train bound for the power plant in Bow at MP 68, approximately 40 miles north of the wye. Similar to the PAR main line, the rail is almost all jointed. There are approximately two miles of welded rail just north of downtown Manchester. Nearly all of the rail is 112 pounds manufactured during the first half of the 1940s. Records supplied by PAR indicate that the last major tie renewals took place in the 1990s, but field inspections indicate that the line seems to be in a near constant state of spot tie renewal to maintain sufficient track structure to safely support the coal train. North to Manchester the line is rated as FRA

Class 3. North to Bow, the nominal track condition is FRA Class 2. Informal inspection of the line indicates that the coal train's requirements force PAR to keep approximately half of the ties in good condition to support and guide the heavy train. Where the vertical profile of the railroad is not restricted by grade crossings, the bed of ballast supporting the coal train tends to be deep with full ballast shoulders.

5.1.8 Railway Bridges

A review of PAR track charts and inspection and rating reports indicate 25 bridges exist along the NHML between Lowell's Gallagher Terminal and Concord. The FRA requires all rail carriers to implement bridge management programs that include annual inspections of railroad bridges and determination of the structure's safe load capacity. PAR reports rate the 25 structures along the route subject to passenger rail restoration generally fair to good, with one bridge noted in poor condition.

The locomotive is the heaviest vehicle in a passenger train with a typical weight of 250,000 pounds. All of the rated bridges along the route are qualified to carry this load. Most of the bridges are rated to safely carry cars with a gross weight of 286,000 pounds or more. The bridge classified as being in the poorest condition is rated to carry a capacity of 263,000 pounds. *The two longest bridges crossing the Merrimack River are not rated and should be inspected before passenger service is restored.*

5.1.9 Highway Grade Crossings

There are 35 locations identified between Lowell's Gallagher Terminal and Stickney Avenue in Concord where roadways or pedestrian paths cross the railway at grade. Grade crossings are of particular concern as they present the greatest accident hazard on the railway due to the potential for vehicle/pedestrian conflicts with trains. Grade crossings will require sensitive treatment should substantially greater volumes of trains be reintroduced along the route. Federal safety regulations require trains to sound their horns at all grade crossings. A federally sanctioned "quiet zone" may be established cooperatively with the local community working with the railroad to make substantial investments that reduce the likelihood of accidents.

The density of 35 crossings along the 48-mile route is relatively low for a suburban railway. The railway generally hugs the bank of the Merrimack River and only several of the streets are heavily travelled. Most of the grade crossings lead to relatively small riverfront residential enclaves or industrial sites. Of the 35 grade crossings, 21 are public roads, 13 are private driveways, and one is an informal community crossing.

Public grade crossings are roadways under the jurisdiction of, and maintained by, a public authority. Private grade crossings are on privately-owned roadways, such as those leading into an apartment complex, housing estate, or commercial/industrial development. A private crossing is not intended for public use and is not maintained by a public road authority. Nationwide, there are approximately 148,000 public crossings and 95,000 private crossings.

- **Lowell**: No grade crossings on the Study corridor in the City of Lowell
- **Chelmsford**: Three private crossings in the Town of Chelmsford; one of these actually functions as a public crossing since it leads into a substantial new residential development on the riverfront

- **Tyngsborough**: Two private crossings in the Town of Tyngsborough; one leads to an older established residential enclave, the other to several commercial buildings and a boat launching ramp
- **Nashua**: Four public crossings in the City of Nashua, three of which are heavily travelled; there is also one private unprotected crossing and one informal crossing used by local residents to recreationally access undeveloped land along the riverfront
- **Merrimack**: Four private crossings in the Town of Merrimack, all of which are lightly travelled
- **Bedford**: No public or private grade crossings in the Town of Bedford
- **Manchester**: Thirteen public and one private crossing in the City of Manchester; seven crossings are located along a single mile of the route adjacent to Manchester's Mill District; Granite Street is undoubtedly the most heavily trafficked crossing along the Study corridor
- **Hooksett**: Two public crossings in the Town of Hooksett; neither grade crossing is heavily travelled
- **Bow**: Two public and two private grade crossings in the Town of Bow; three lead into a single farm or industrial plant and one is a busy local street
- **Concord**: No roadway grade crossings along the Study corridor in the City of Concord

5.1.10 Current Rail Passenger Services

On a typical weekday in the spring of 2013, Lowell was served by 44 MBTA revenue trains to and from Boston's North Station. The 25-mile trip serves up to seven intermediate station stops. The running time between Lowell and Boston ranges between 45 and 49 minutes with a maximum allowable speed of 70 mph. Six weekday non-revenue deadhead trains run between Lowell and Boston to stage the service because there is no facility for the overnight storage or maintenance of the trains in Lowell. Typical weekday MBTA ridership on the entire line is 17,500 passenger trips, including both northbound and southbound travel. Lowell is the busiest passenger station on the line with 4,280 weekday boardings and alightings.

The current NHML MBTA service provides 64 weekday passenger trains to and from North Station (see Table 5.3). Of those trains, 44 are revenue trains running between Boston and Lowell and six are the aforementioned non-revenue deadhead trips. The remaining 14 trains are a mix of peak-period, short-turn trains between Woburn and Boston and a variety of express and reverse-peak trains running between Boston and Haverhill via the Wildcat Route.[15] The line also serves 10 Amtrak *Downeaster* trains from Portland to Boston North Station via Woburn and the Wildcat Route.

[15] The Wildcat Route is a single-track, 2.88 mile railroad branch line that connects the MBTA Lowell Line in Wilmington, Massachusetts to the MBTA Haverhill Line at Wilmington Junction.

Table 5.3: MBTA Service, Ridership and Revenue Statistics (2012$)

Station	MP	Amtrak Weekday Revenue Trains	MBTA				
			Weekday Revenue Trains	Typical Weekday Southbound Boardings	Cash Fare	Average Revenue per Passenger Boarding	Typical Total Weekday Passenger Revenue
Lowell	25.5	-	44	2,141	$6.75	$6.67	$28,566
North Billerica	21.8	-	44	1,427	$6.25	$6.38	$18,195
Wilmington	15.2	-	47	758	$5.25	$5.09	$7,711
Woburn	12.6	10	57	1,743	$4.75	$4.77	$16,640
Mishawum	11.9	-	6	50	$4.75	$4.95	$495
Winchester	7.8	-	49	1,002	$4.25	$4.34	$8,701
Wedgemere	7.3	-	48	740	$4.25	$4.36	$6,459
West Medford	5.5	-	49	884	$1.70	$1.83	$3,244
North Station	0.0	10	58	n/a	n/a	n/a	n/a
Totals	-	10	58	8,745	-	$5.15	$90,011

Source: MBTA Conductor's Audit Reports Thursday - February 9, 2012 and Jacobs Analysis

The Lowell service requires four train sets in the morning and five train sets in the afternoon. As shown in Table 5.4, the peak five trains are required to be six, five, six, seven, and five cars long. The seven-car train regularly carries 652 passengers. All but one car assigned to the Lowell service is a single-level coach. The maximum length of any train berthing at North Station is eight cars. As ridership on the NHML grows, the number of higher capacity bi-level coaches on the route will need to be increased.

Table 5.4: MBTA NHML Peak Train Lineup

Set	Peak Train	Single-Level Coaches	Bi-Level Coaches	Seats	Peak Riders
N	310	6	-	684	579
O	304	4	1	636	493
P	306	6	-	684	600
Q	308	7	-	798	652
R	327	5	-	570	480

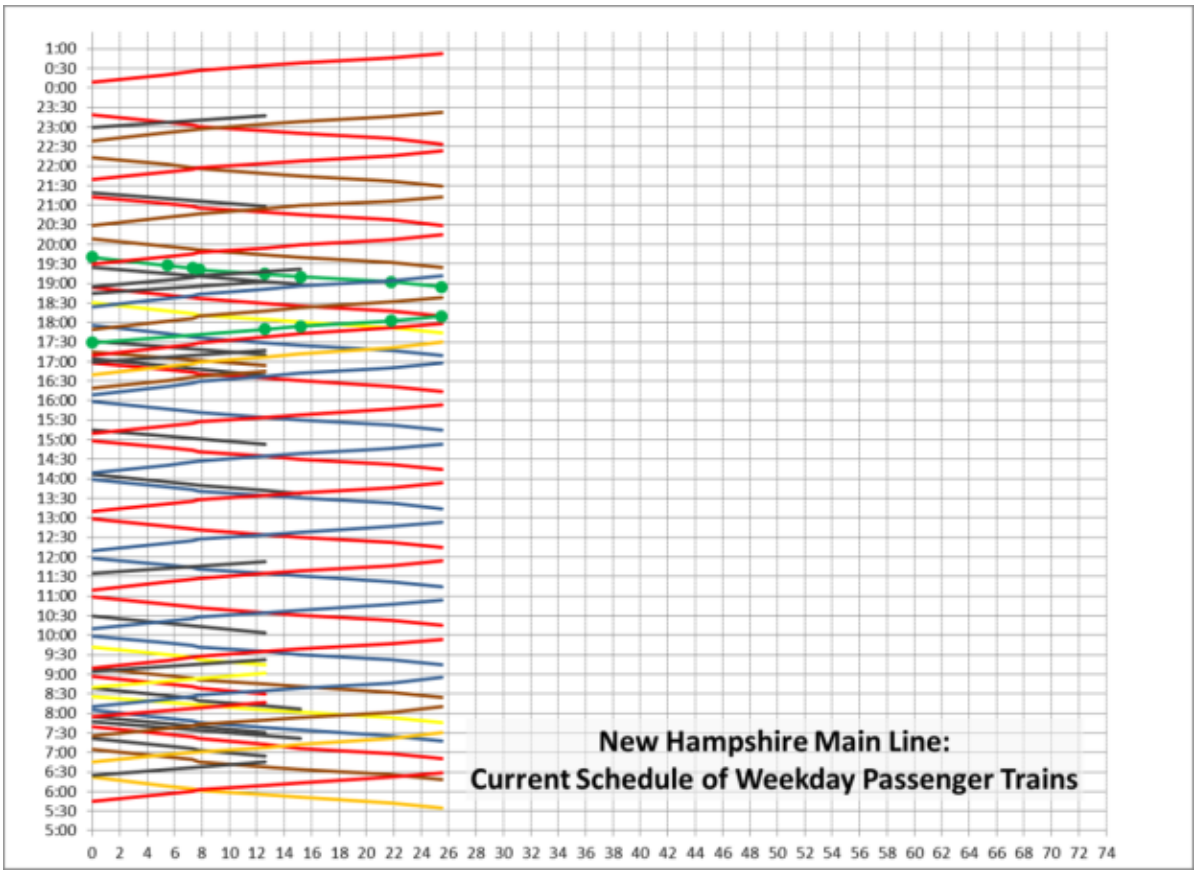
Source: North Side Equipment Cycle Seating Requirements for 198 Scheduled Weekday Trains, MBTA, February 29, 2012

A stringline diagram, also referred to as a time-distance diagram, is helpful for planning the flow of railroad traffic. These diagrams are a graphical depiction of the timetable and provide a visual representation of trains scheduled to operate on a corridor. The diagrams show distance and station locations along the x-axis and time along the y-axis. The stringlines show the time and location of each scheduled trip. The slope of line indicates direction and relative speed with upward lines representing northbound trips and downward lines representing southbound trips. Intersecting lines show when and where trains will meet and identify where passing sidings or double tracking will be required.

A stringline diagram illustrating current weekday passenger operations on the line is shown in Figure 5.4. For reference, North Station is located at MP 0 and Lowell is at MP 25. Nashua, Manchester, and

Concord are located at MPs 39, 55, and 73, respectively. The timetable of services can be found in *Section 6: Service Alternatives*.

Figure 5.4: Existing NHML MBTA Passenger Rail Services



Stringline diagrams are used to identify potential schedule conflicts (meets/passes), potential open slots for new service, and resource planning (crews, locomotives, etc.). The schedule is also impacted by certain track restrictions that determine line capacity such as physical track layout, number of tracks, and the number and spacing of sidings. If a stringline becomes vertical, it means that the train must stop at that location for the duration of the vertical line. Required changes in scheduled departures and arrivals, station dwell times, and train meets can be identified and adjusted in the stringline diagram and then used to update the timetables.

Figure 5.5: Amtrak *Downeaster* Service

Amtrak *Downeaster* service between North Station and Brunswick, Maine also operates on the NHML line as far north as Woburn (Figure 5.5). It then uses the "Wildcat Route" to travel northeasterly Haverhill, Massachusetts and on to Maine. Each *Downeaster* train serves passengers to and from the north at North Station and

Woburn. No southbound Amtrak passengers are allowed to board at Woburn and no northbound tickets to Woburn are sold from North Station. The *Downeaster* averages 1,400 passengers per day at all stations. The typical daily passenger traffic at Woburn is 30 boardings and alightings.

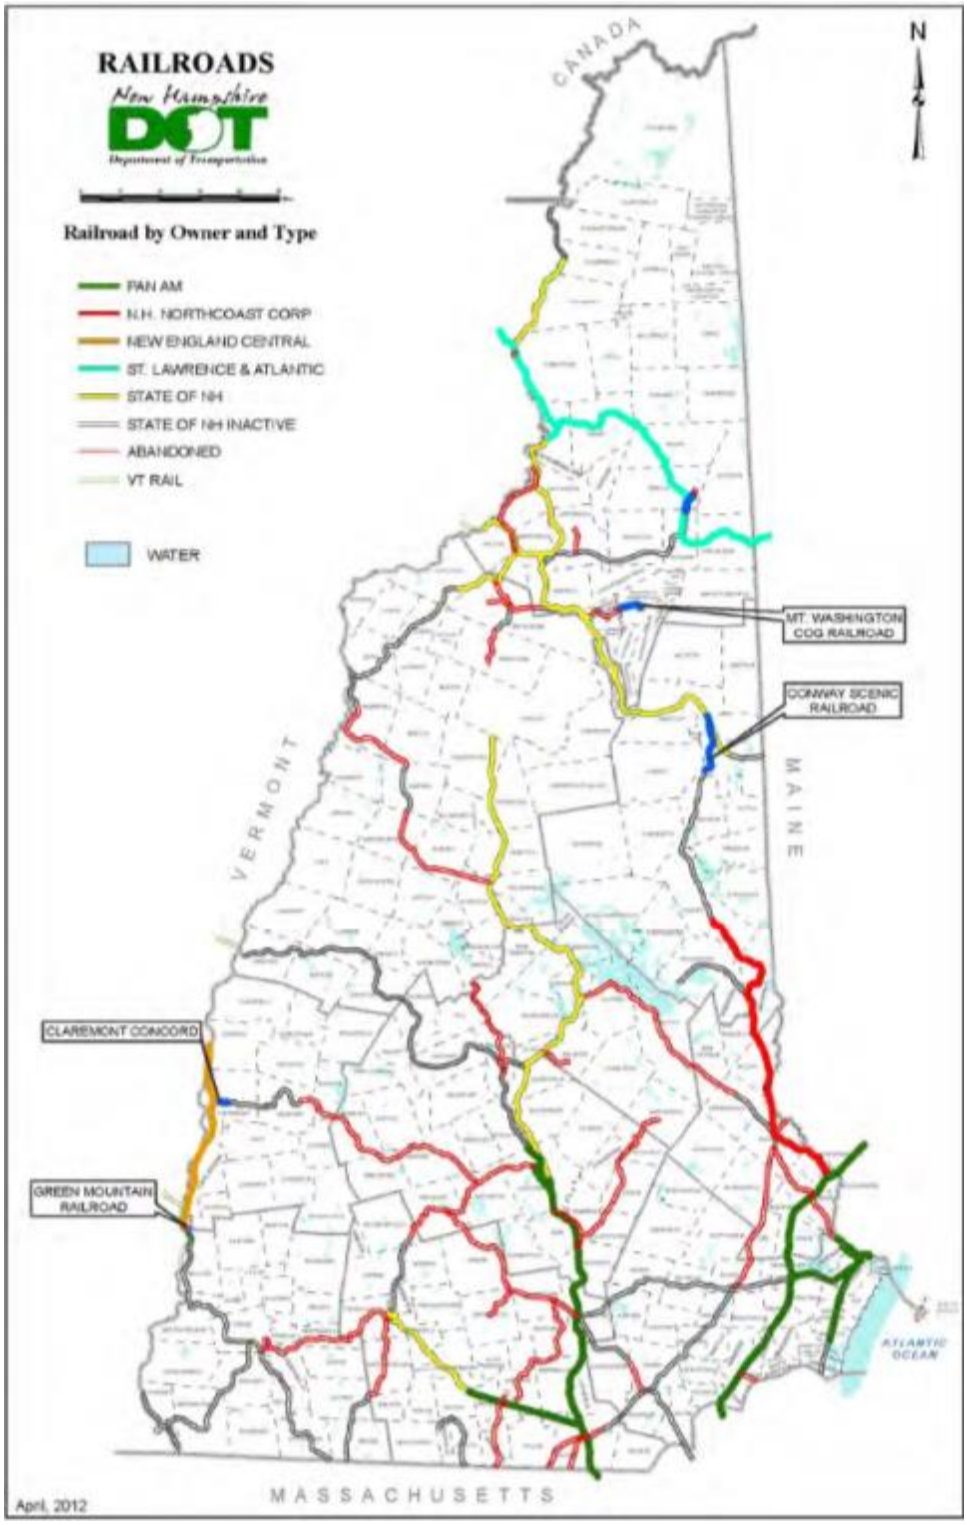
5.1.11 Rail Freight Service

The New Hampshire rail system is composed of five primary owners of the railroad lines: PAR, New Hampshire Northcoast Corporation, New England Central Railroad, St. Lawrence & Atlantic Railroad, and the State of New Hampshire (see Figure 5.6). In addition to these five primary owners, four of which are also railroad operators, six additional freight railroads either operate on small segments of track in New Hampshire or over track owned by others, such as the state-owned lines Claremont-Concord Railroad, Green Mountain Railroad, Milford-Bennington Railroad, New Hampshire Central Railroad, New England Southern, and Twin State Railroad.

New Hampshire's population and industry are well served by three intermodal terminals located near the state's borders in Worcester, Massachusetts; Ayer, Massachusetts; and Auburn, Maine. New Hampshire and the rest of New England is often referred to as a cul-de-sac in the national rail network, since the area is primarily a freight destination, and no major rail routes traverse the region. Rail volumes in New England tend to be considerably lower than other parts of the nation, with only a single Class I rail connection between Boston and Albany, New York.

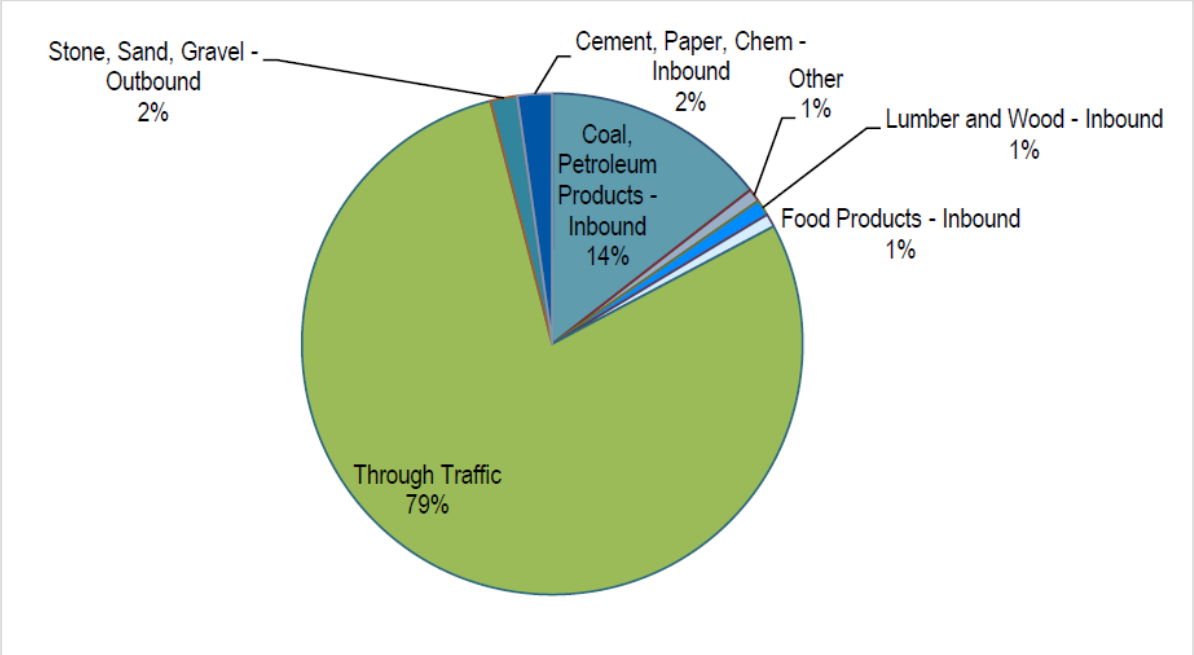
Approximately 85 percent of national rail freight tonnage is bulk commodities, such as agriculture and energy products, automobiles and components, construction materials, chemicals, equipment, food, metals, minerals, and pulp and paper. Figure 5.7 illustrates that the commodities most commonly shipped to New Hampshire are coal and petroleum products bound for local consumption.

Figure 5.6: New Hampshire Railroads by Owner and Type



Source: New Hampshire State Rail Plan, 2012

Figure 5.7: New Hampshire Freight Rail Traffic by Commodity/Direction (% of carloads)



Source: New Hampshire State Rail Plan, 2012

The commodity most commonly shipped from New Hampshire is sand and gravel bound for cement and asphalt plants in Massachusetts. Almost 80 percent of the rail cars moving through the state are through movements between Maine, Eastern Canada, and the balance of the U.S.

The NHML connects to the national freight network only at Lowell, Massachusetts. This corridor currently receives three quarters of all rail freight tonnage shipped into New Hampshire. While the freight received is quite diverse, traffic flow is dominated by coal for electric generation shipped to Bow, New Hampshire. Clay, concrete, glass, and stone also comprise much of the remaining rail freight tonnage moving on the corridor. Other products shipped along the corridor include farm products, lumber and wood products, food, chemicals, and some nonmetallic minerals. Significantly more freight rail traffic is shipped into southern New Hampshire than is shipped out. Shippers categorize the small amount of outbound freight rail traffic as miscellaneous freight.

Most rail traffic currently shipped to New Hampshire is for local consumption and the volume of outbound rail traffic other than building materials is quite minor. Unless there is a major shift in New Hampshire's economy to produce, process, or consume large volumes of bulk commodities, it is unlikely that the total volume of rail traffic to or from the Granite State will grow at a rate that varies significantly from expected population growth. That is not to say that rail freight in the state would not benefit from improvements to a key rail line serving the state's major population centers, but the magnitude of benefit for long journeys on the national network will likely be relatively small.

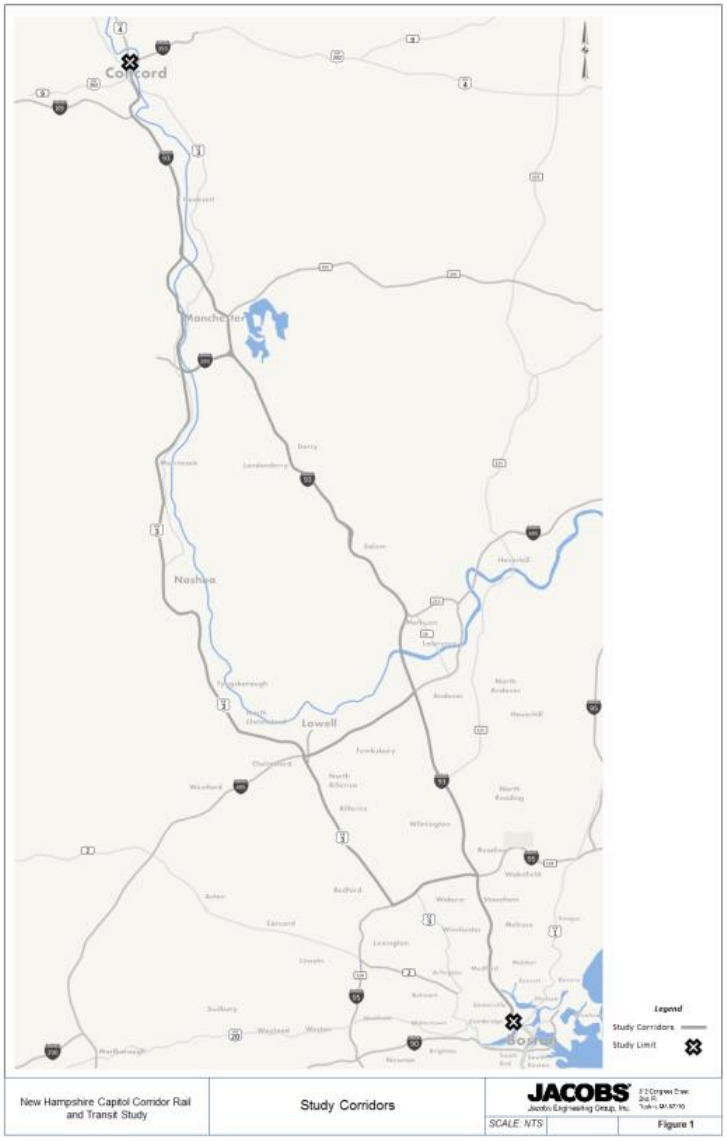
5.2 Highway Facilities and Level of Service

The Capital Corridor's limited access highways that connect New Hampshire's major population centers to metropolitan Boston are I-93, US Route 3/Everett Turnpike, I-95/Route 128, I-293, and, I-495. An overall corridor Study map showing the subject corridors is shown in Figure 5.8. These highways cover 268 round trip miles of limited access freeway facilities and interchanges, shared between the States of New Hampshire and Massachusetts. The breakdown on the corridor mileage is as follows:

- 130 round trip miles on I-93
- 22 round trip miles on I-293
- 98 round trip miles on US Route 3
- 22 round trip miles on Route 128/I-95
- 18 round trip miles on I-495

Most analysis focuses on I-93 since it is the only direct link into Boston from the Study corridor. US Route 3, I-293, I-95/Route 128, and I-495 all feed into I-93 for the purposes of travel along the Capitol Corridor to and from the regional core.

Figure 5.8: Study Corridor Highways



5.2.1 Highway Geometrics

I-93 southbound offers three lanes for travel between Hooksett and I-293 where it drops a lane until it reaches the state line in Massachusetts. A fourth general purpose (GP) lane is added in the vicinity of Wilmington near the Route 125 interchange.

Near Medford and Somerville, Massachusetts, south of Exit 30, I-93 southbound splits into one high occupancy vehicle (HOV) lane and three GP lanes. After Exit 28, the three GP lanes on I-93 southbound drop to two GP lanes for approximately 1,360 feet before regaining the third GP lane at Exit 29.

I-93 is currently being widened to four GP travel lanes in each direction in New Hampshire between Exits 1 and 5 from the Massachusetts state line to Manchester, New Hampshire for a distance of approximately 19.8 miles. The project is expected to be completed in 2018. For the purposes of this Study, the widening project is presumed to be complete.

US Route 3/The Frederick Everett Turnpike southbound generally carries two GP travel lanes from Concord to I-89 where it adds a third lane. US Route 3 carries three GP lanes from I-89 to the I-93 split.

After the I-93 split, US Route 3 generally carries two GP lanes from Manchester to New Hampshire Route 101, where US Route 3 widens and fluctuates between three and four lanes. It narrows and fluctuates between two and three GP lanes from Exit 13 in Merrimack, New Hampshire to Exit 8 in Nashua, New Hampshire. From Exit 8 and to the Massachusetts state line, US Route 3 fluctuates between four and three GP lanes. In Massachusetts, US Route 3 generally carries three GP lanes from the state line to Route I-95/128 in Burlington, Massachusetts.

I-95/Route 128 northbound generally carries four GP lanes between US Route 3 and I-93. North of I-93, I-95 has a lane drop from four to three GP travel lanes.

I-495 northbound generally carries three GP lanes between US Route 3 and I-93.

I-93 northbound generally carries four GP travel lanes from Exit 29 in Somerville, Massachusetts to Exit 41 in Wilmington, Massachusetts. After Exit 41, a lane is dropped and there are three GP lanes up to the state line. In New Hampshire, I-93 northbound carries two GP lanes from the state line to Exit 5 in Manchester, New Hampshire. After Exit 5, I-93 northbound fluctuates between two and four lanes up to Exit 7 where it generally settles to three GP lanes up until the US Route 3/Frederick Everett Turnpike merge. As noted above, I-93 is currently being widened to four GP travel lanes in each direction in New Hampshire from the state line to Manchester, New Hampshire for a distance of approximately 19.8 miles.

US Route 3 northbound generally carries three GP travel lanes from Burlington, Massachusetts though the state line to Merrimack, New Hampshire. Starting before Exit 10, US Route 3 northbound fluctuates between three and two lanes up to the I-93 merge. North of the I-93 merge, US Route 3 northbound fluctuates between three and four GP lanes. After the I-89 interchange, US Route 3 northbound carries two GP lanes up to Concord, New Hampshire.

I-95/Route 128 southbound carries three GP travel lanes into the I-93 interchange and adds a fourth lane south of the interchange, which carries through to and beyond US Route 3.

I-495 southbound carries three GP travel between I-93 and US Route 3.

5.2.2 Breakdown Lanes and Managed Lanes

Peak period breakdown travel lanes on I-93 northbound and southbound between Exits 45 and 47 exist at this time, but will be permanently removed with the reconstruction of the Methuen interchange at Route 110/113 and I-93.

An existing managed lane on I-93 southbound begins in Medford, Massachusetts. After Exit 30 and before Exit 28, I-93 southbound splits into one HOV lane and three GP lanes. There is a four-foot painted buffer separation between the HOV lane and the adjacent GP lanes. The HOV lane ends at the Leonard P. Zakim Bunker Hill Bridge at the I-93/Route 1 merge. There are no other entrances or exits for the southbound HOV lane between the Mystic Avenue on-ramp entrance and the Zakim Bridge. Buses, carpools (defined as two or more occupants), motorcycles, and vanpools using the HOV lane can save up to 10 minutes during the morning peak-period commute. The HOV restrictions apply between 6:00am and 10:00am, Monday through Friday.

5.2.3 Highway Level of Service

Level of service (LOS) is commonly used to describe the operating conditions for ground transportation facilities. LOS for freeway facilities is calculated from vehicular speed, volume, and density. LOS ranges from LOS A to F, where LOS A describes free-flow operations, LOS E describes operations at capacity, and LOS F describes breakdown conditions and unstable traffic flow.

LOS analysis for freeway sections is based upon density of vehicles. Density is measured in passenger-cars-per-mile-per-lane (pc/mi/ln). LOS is a term used to denote different operating conditions that occur at a given roadway segment under various traffic volume loads. It is a qualitative measure of the effect of a number of factors including roadway geometrics, speed, travel delay, freedom to maneuver, and safety.

The LOS for ramp merge and diverge points are based upon the density of vehicles upstream of the merge and downstream of the diverge points. Weave sections are defined as the roadway segment bounded by an on-ramp followed with an off-ramp, creating a potential conflict for vehicles trying to enter the roadway and vehicles trying to exit the roadway within the same stretch of pavement.

Given the regional scale of this Study, LOS and volume-to-capacity (v/c) were identified as appropriate performance measures to evaluate the limited access freeway conditions during the weekday peak hours. The LOS criteria for freeway sections, ramp junctions, and weaving segments are shown in Table 5.5.

Table 5.5: Highway LOS Thresholds

LOS	Freeway	Ramps	Weaving
	Density (cars/mile/lane)	Density (cars/mile/lane)	Density (cars/mile/lane)
A	0 – 11	0-10	0-10
B	> 11 – 18	> 10-20	>10-20
C	> 18 – 25	>20-28	>20-28
D	> 25 – 35	>28-35	>28-35
E	> 35 – 45	>35	>35-43
F	Overcapacity	Overcapacity	>43

Source: 2000 Highway Capacity Manual

Year 2013 existing weekday morning peak-hour LOS and v/c ratios for inbound traffic towards metropolitan Boston are shown in Figure 5.9. Under current conditions, there is severe traffic congestion inbound towards Boston during the weekday morning peak hour. The vehicular demand exceeds capacity with a v/c ratio greater than 1.25 from Exits 36 to 27. Various sections between Exits 36 and 27 have LOS E conditions. I-93

between I-95/Route 128 and I-495 is generally over-capacity with LOS E and F conditions. I-95/Route 128 between US Route 3 and I-93 is generally over-capacity with traffic congestion.

The existing weekday evening peak-hour LOS and v/c ratios for outbound traffic from metropolitan Boston are shown in Figure 5.10. Under current conditions, there is severe traffic congestion outbound from Boston during the weekday afternoon peak hour. Vehicular demand exceeds capacity with a v/c ratio greater than 1.25 for various segments between Exits 27 to 39. Various sections between Exits 27 and 39 have LOS E and F conditions. North of Exit 39 and up to I-495, I-93 is generally at or over capacity. I-95/Route 128 between US Route 3 and I-93 is generally over-capacity with traffic congestion, and predominately at or near capacity closer to US Route 3.

Figure 5.9: Year 2013 Morning Peak-Hour Highway LOS

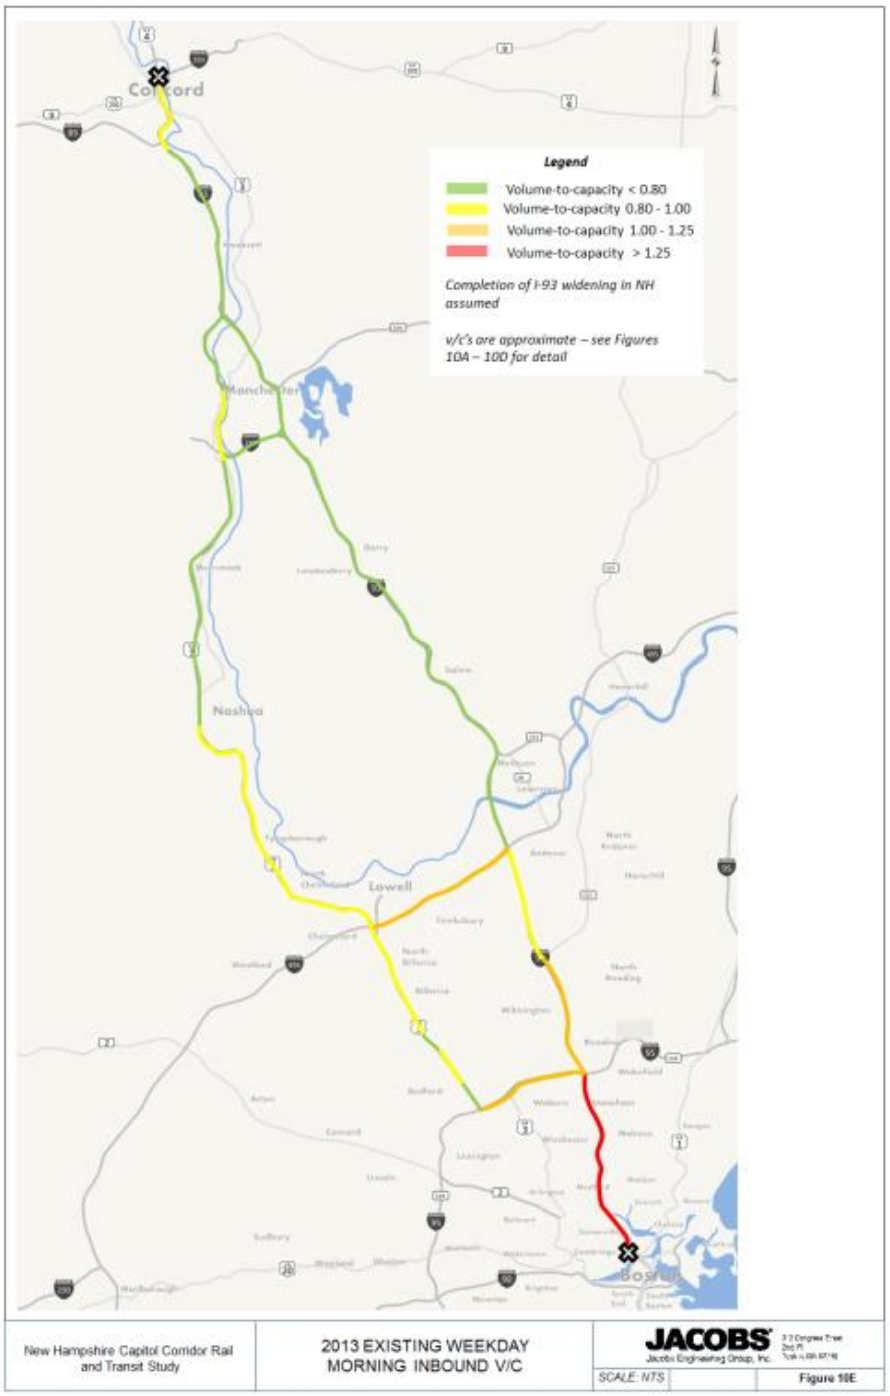


Figure 5.10: Year 2013 Peak-Hour LOS

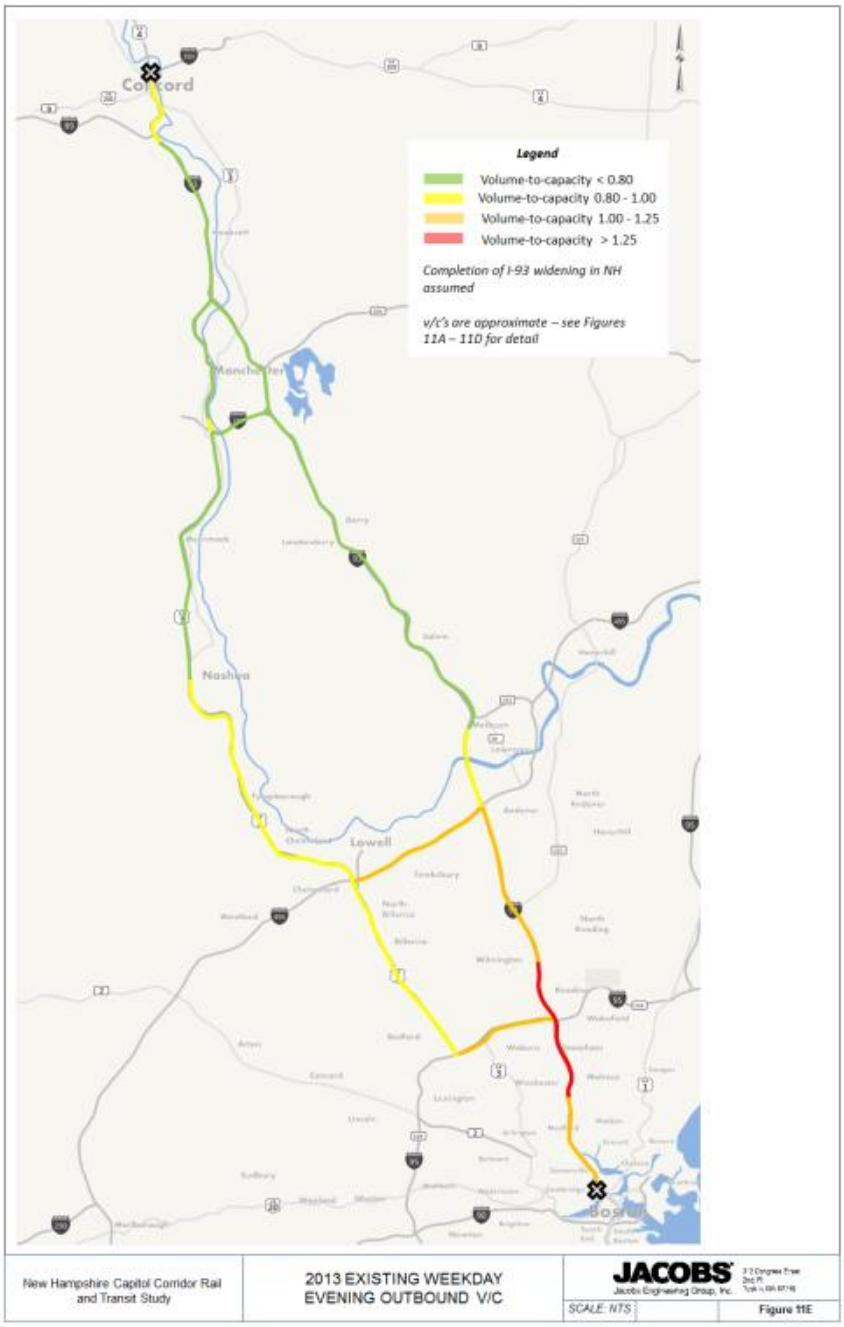

5.2.4 Peak Travel Speeds

Travel speed and time data for the network was collected via real-time, GPS-equipped, anonymous cell phone technology – through two internet mapping sources (www.google.com/maps and www.bing.com/maps). The internet data established current travel speeds and hot spot locations for congestion between the major population centers in New Hampshire and Boston. The data collection was undertaken in June 2013 during the weekdays – excluding Mondays and Fridays.

Year 2013 existing weekday morning peak-period travel speeds for inbound traffic towards Boston are shown in Figure 5.11. The existing weekday evening peak-period travel speeds for outbound traffic from metropolitan Boston are in Figure 5.12.

Figure 5.11: Year 2013 Weekday Morning Inbound Speeds

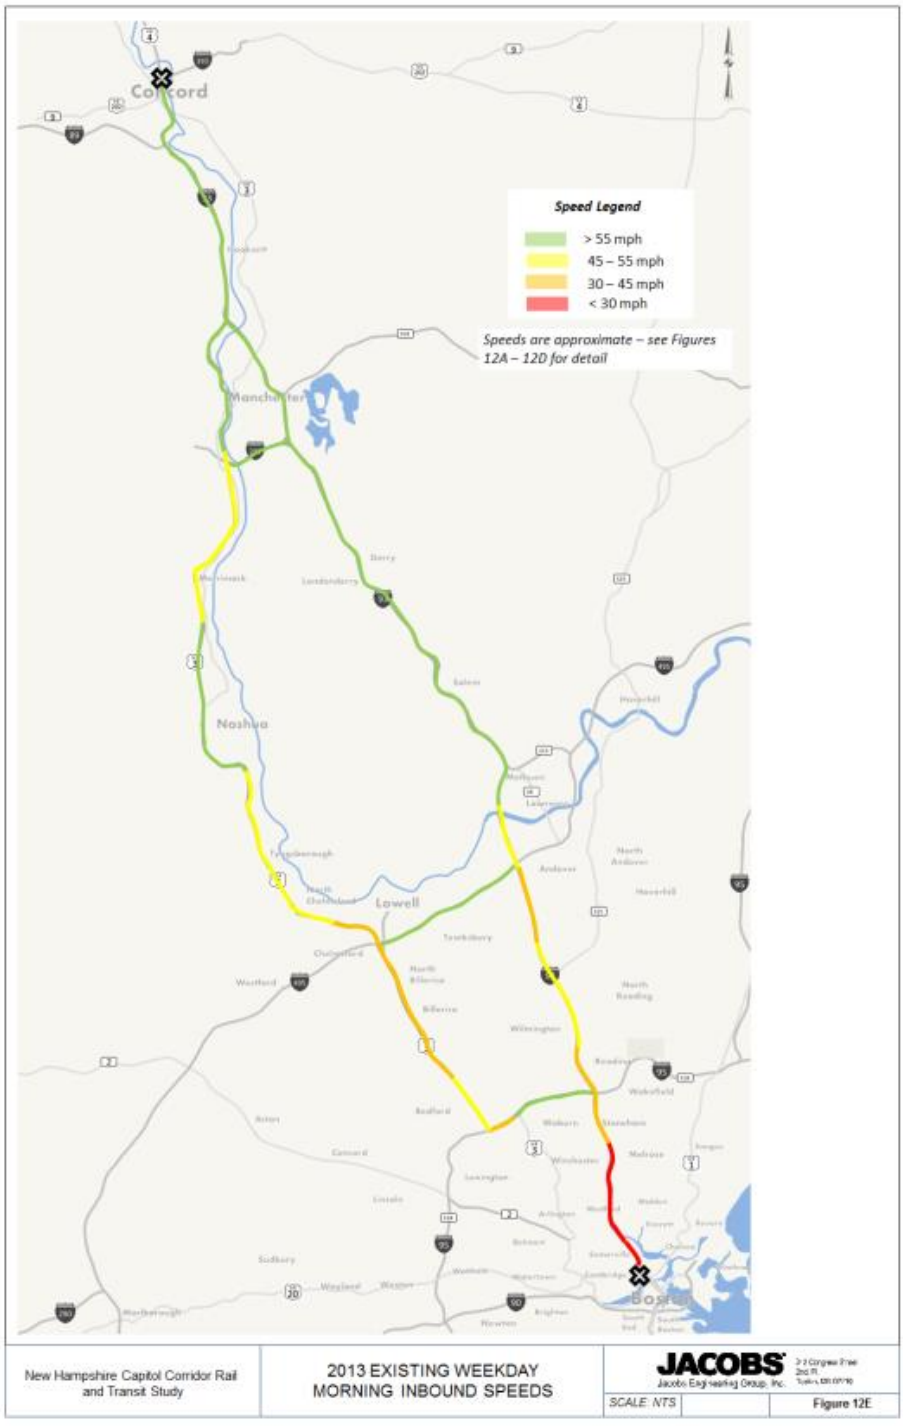

Figure 5.12: Year 2013 Weekday Evening Outbound Speeds

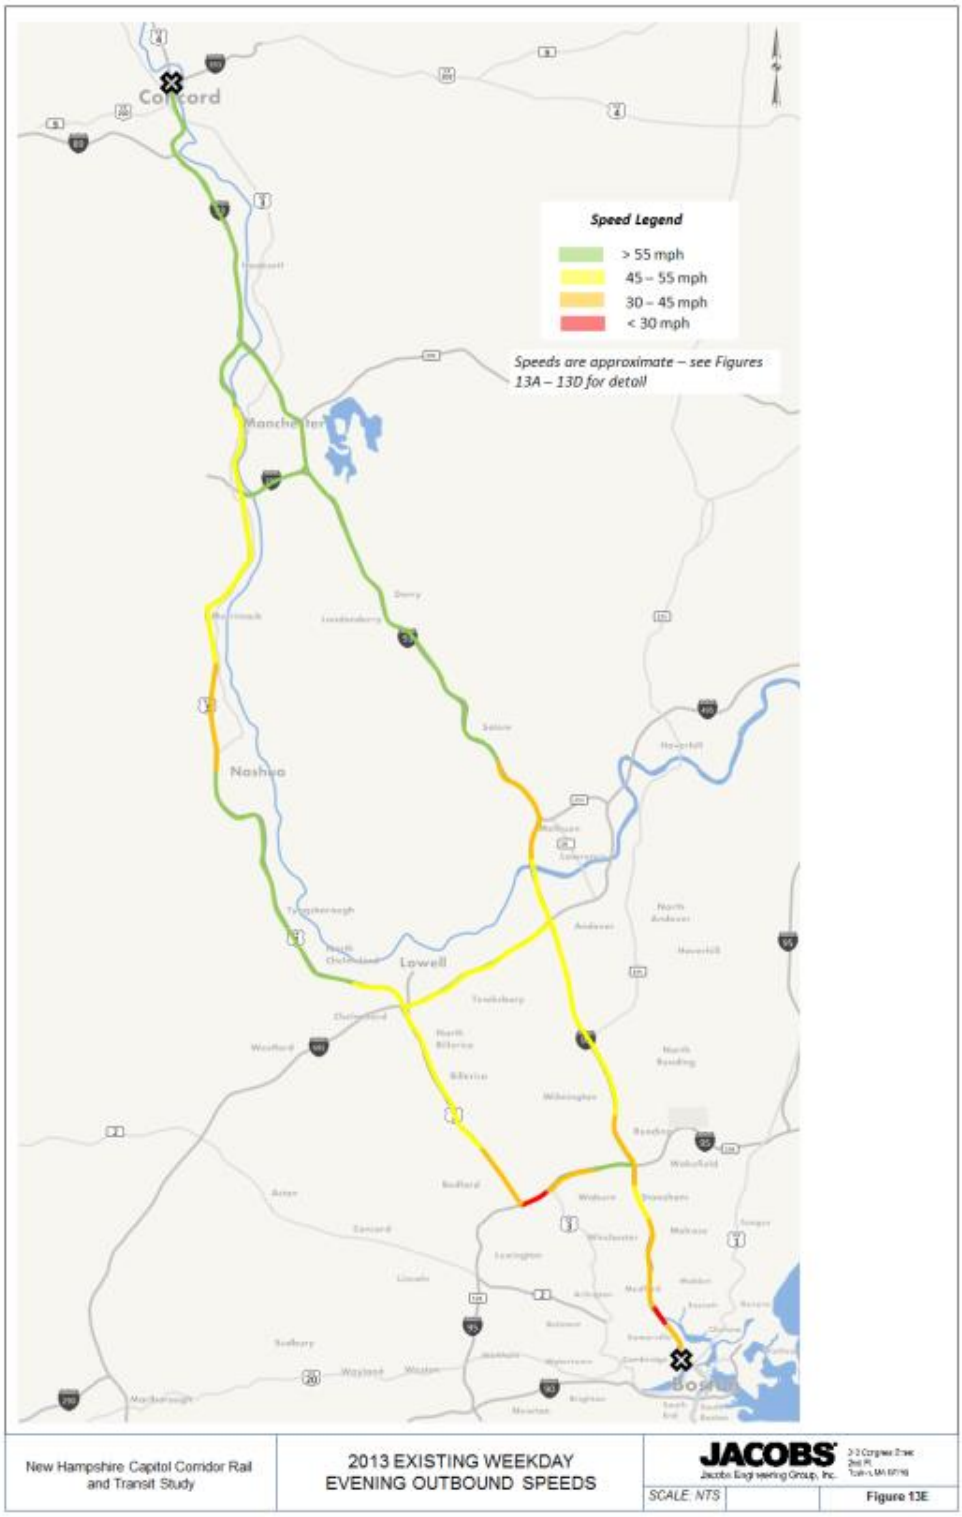

5.2.5 Travel Time Contours

Year 2013 existing weekday morning peak-hour travel time contours for inbound traffic towards Boston are shown in Figure 5.13. The existing weekday evening peak-hour travel time contours for outbound traffic from Boston are shown in Figure 5.14.

Figure 5.13: Year 2013 Evening Inbound Peak-Period Travel Time Contours

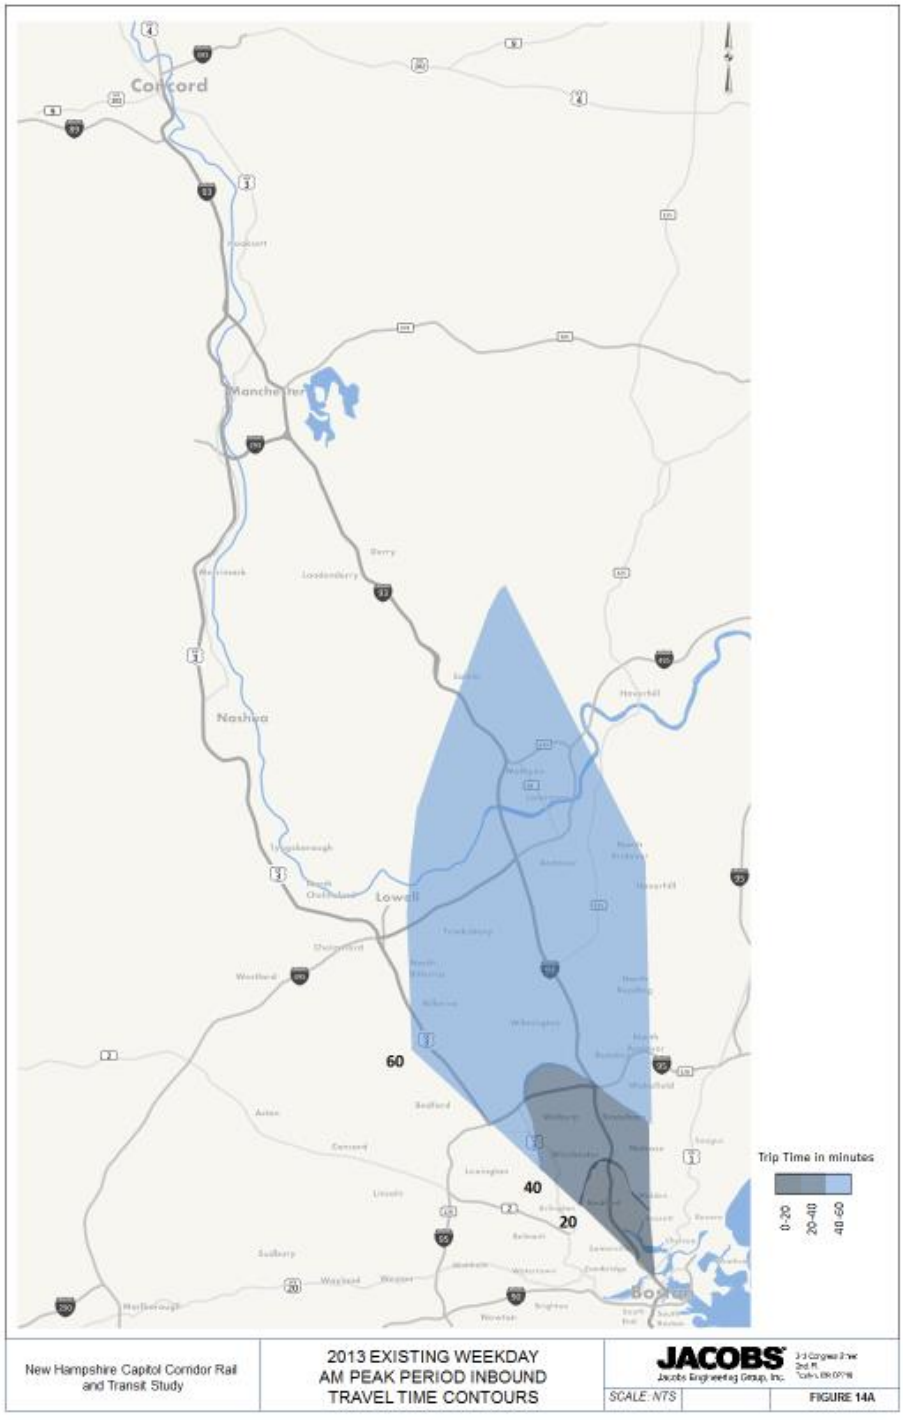

Figure 5.14: Year 2013 Evening Outbound Peak-Period Travel Time Contours

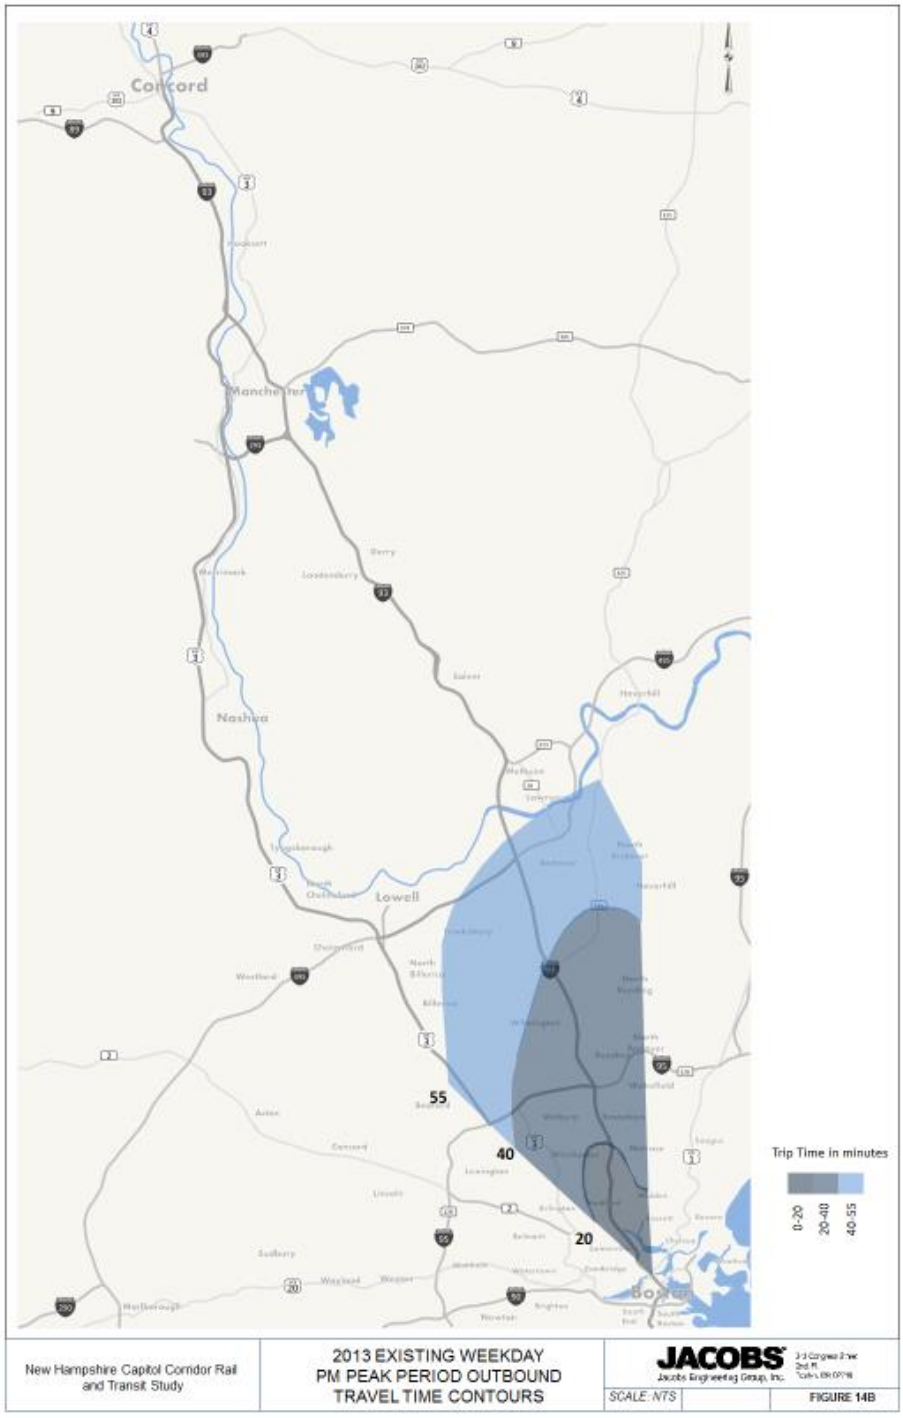


Travel times from Concord to Boston during the inbound morning commute are bottom-heavy due to the gradual increase in congestion approaching Boston. Nearing Boston, congestion is severe with speeds less than 30 mph. Travel times inbound currently take up to 20 minutes from Medford, Malden, and Everett – areas only four miles from Boston – with an average speed of 12 mph. Expanding radially

by another four miles, the travel times into Boston double to 40 minutes – still with an average speed of 12 mph. Between I-95 and I-495, travel times into Boston can take up to 60 minutes by vehicle.

Travel times outbound from Boston during the afternoon commute are top-heavy due to the severe congestion experienced exiting Boston northbound – but not as severe as the morning peak hour. Travel times outbound currently take up to 20 minutes to Medford, Malden, and Winchester – areas only seven miles from Boston – averaging just over 20 mph. Expanding radially by another seven miles, the travel times exiting Boston double to 40 minutes – still averaging just over 20 mph. Travel times to Lawrence currently take less than 60 minutes, and commutes to beyond Salem, New Hampshire take less than 70 minutes. Travel times from Boston to Concord take less than 90 minutes in weekday afternoon peak-hour traffic.

5.2.6 Highway Conditions Summary

Severe traffic congestion is evident entering and exiting Boston via I-93 North during the weekday peak periods. When travel speeds drop below 30 mph, traffic volumes are generally understood to exceed road capacity by over 25 percent. Average peak-period speeds on I-93 have been shown to drop to as low as 12 mph for the last eight miles inward to Boston.

The current freeway infrastructure on I-93 North is a contributing factor to the severe traffic congestion experienced entering and departing Boston. After Exit 28 in Somerville, the three GP lanes on I-93 southbound drops to two GP lanes for over 1,000 feet before regaining the third lane at Exit 29. This lane drop, less than four miles away from Boston, is currently a choke point causing severe congestion on I-93 on typical weekday morning conditions.

In New Hampshire, I-93 North is currently being widened to four GP travel lanes in each direction between Exits 1 and 5 from the Massachusetts state line to Manchester, New Hampshire for a distance of approximately 19.8 miles. This will add tremendous peak-hour vehicular capacity and facilitate more efficient traffic operations in New Hampshire.

However, the future lane imbalance with the I-93 SB lane drop from four lanes to three lanes between the New Hampshire state line and Exit 41 in Wilmington, Massachusetts for approximately 11.5 miles is expected to be a key choke point and source of congestion in the future morning peak period.

In the northbound direction during the afternoon peak period, after Exit 41 and the Route 125 interchange, I-93 northbound drops a lane and consist of three GP lanes to the New Hampshire state line. In the future, this reduction from four to three lanes at Exit 41, and back to four lanes in New Hampshire is expected to be choke point and a source of peak-hour congestion in the weekday afternoon.

Additionally, the peak-period breakdown travel lanes on I-93 northbound and southbound between Exits 45 and 47 will permanently be eliminated with the reconstruction of the Methuen interchange at Route 110/113 and I-93.

With regards to managed lanes and the benefits of higher travel speeds and higher person throughputs, an existing managed lane on I-93 southbound begins in Medford, Massachusetts. After Exit 30 and

before Exit 28, I-93 southbound splits into one HOV lane and three GP lanes. There is a four-foot painted buffer between the HOV lane and the adjacent GP lanes. The HOV lane ends at the Bunker Hill Bridge at the I-93/Route 1 merge. There are no other entrances or exits for the southbound HOV lane between the Mystic Avenue on ramp entrance and the Zakim Bridge.

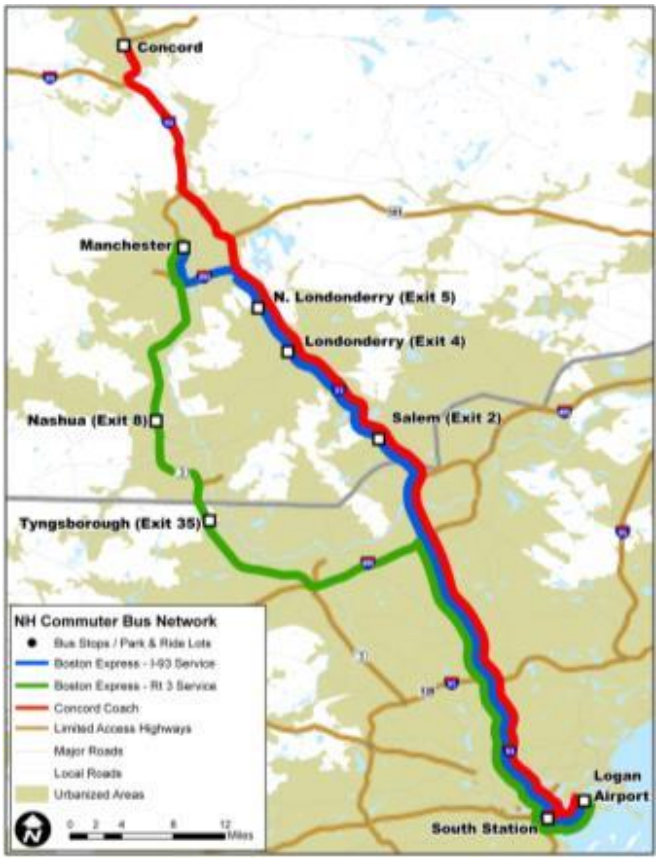
While there is a managed lane for I-93 southbound that spans approximately two miles, it does not span the nine mile breadth of inbound congestion during the morning peak period, which begins just south of I-95/Route 128. There are no managed lanes northbound on I-93 to improve travel speeds or user throughput during the weekday afternoon peak period.

5.3 Corridor Bus Services

In total, seven regional and four local bus transit operators provide service within New Hampshire and intercity service to Boston and beyond. All of these services are subject to the same highway congestion that affects automobile traffic on I-93 and other elements of the corridor highway network. Each of these services has access to the HOV lane on I-93 that travels 2.5 miles between the Shore Drive overpass in Somerville and the Zakim-Bunker Hill Bridge, potentially saving up to 10 minutes compared with morning peak travel in the GP lanes.

BX provides the primary commuter service from the Study area to Boston along the heavily congested Massachusetts segments of Interstate 93. The service was initially introduced by NHDOT as a mitigation measure during highway construction along I-93. Concord Coach also provides intercity service to Boston along the central spine of New Hampshire as far north as Berlin, New Hampshire. Figure 5.15 shows BX and Concord Coach bus routes. In Massachusetts, the MBTA and Merrimack Valley Regional Transit Authority (MVRTA) also provide commuter service to Boston along I-93 from communities to the north of the city.

Figure 5.15: BX and Concord Coach Bus Routes



Additional New Hampshire regional bus service between communities outside of the Study area and to Boston operates through the Study area or along Study corridor segments. Dartmouth Coach provides service from Dartmouth University in Hanover, New Hampshire and White River Junction, Vermont to Boston and travels non-stop through the Study area along I-89 and I-93.

Service to and from the New Hampshire Seacoast is operated by C&J from Dover, Durham; Portsmouth,

New Hampshire and Newburyport, Massachusetts to Boston and New York City. Finally, Greyhound provides intercity service from Boston to Manchester, Concord, and points north and west and from Boston to Nashua via Worcester and Leominster, Massachusetts.

Local bus service within the New Hampshire Study area portion is provided by Concord Area Transit (CAT), Manchester Transit Authority (MTA), and Nashua Transit System (NTS). Local bus service in Massachusetts is also provided within the Study area by the Lowell Regional Transit Authority. Interconnections between these local providers are limited.

5.3.1 Boston Express (BX)

BX is a privately operated network of commuter buses that were originally procured by the State of New Hampshire as a mitigation measure for the expansion project on I-93. NHDOT allocated capital investment to acquire the buses and construct a number of park-and-ride facilities.

Two routes provide service to Boston South Station from the downtown Manchester bus terminal on Canal Street at Granite Street and via park-and-ride facilities on Route 3 or I-93. The Route 3 service makes stops at Exit 8 in Nashua and Exit 35 in Tyngsborough, Massachusetts, while the I-93 service makes stops at Exit 5 in North Londonderry, Exit 4 in Londonderry, and Exit 2 in Salem.

The I-93 service operates 24 peak period trips per day at 15-30 minute headways and 31 off-peak trips 30-60 minute headways. The Route 3 service operates 14 peak-period trips per day at 20-30 minute headways and 32 off-peak trips per day at 45-120 minutes headways.

Most BX trips follow I-93 directly to Boston South Station, but many of the southbound peak period trips on the I-93 service travel through downtown Boston to serve commuters on the way to or from South Station. Northbound trips to New Hampshire do not circulate through downtown, but depart directly from South Station and travel north on I-93.

Existing traffic congestion along I-93 significantly impacts BX's scheduled travel times. For instance, the 6:30am southbound departure from Londonderry (Exit 4) on the I-93 service is scheduled for a one-hour trip to South Station. Meanwhile, the 9:50am southbound departure is scheduled for a two-hour and 20 minute trip, which is a built-in or induced delay of one hour and 20 minutes.

Average daily ridership on the I-93 service is approximately 1,200 boardings and on the Route 3 service, approximately 600 daily boardings (Tables 5.6 and 5.7).

Table 5.6: BX I-93 Service

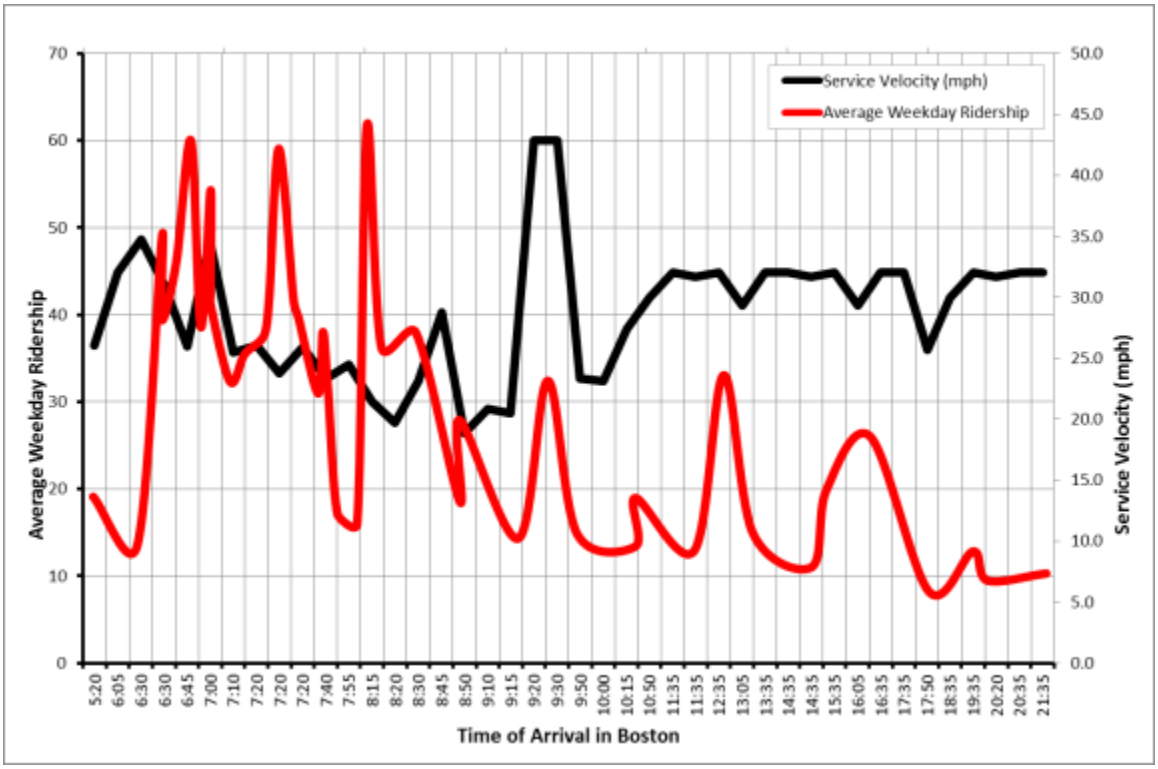
	I-93 Southbound Service	I-93 Northbound Service
Average Weekday Ridership (March 2013)	613	602
Peak Trips	12	12
Off-Peak Trips	17	14
Span of Service	4:00am-9:50pm	7:15am-11:55pm
Peak Headways	20-30 min	15 min
Off-Peak Headways	30-60 min	60 min

Table 5.7: BX Route 3 Service

	Route 3 Southbound Service	Route 3 Northbound Service
Average Weekday Ridership (March 2013)	298	306
Peak Trips	7	7
Off-Peak Trips	16	16
Span of Service	5:30am-8:35pm	7:15am-11:00pm
Peak Headways	30 min	20-30 min
Off-Peak Headways	90-120 min	45-90 min

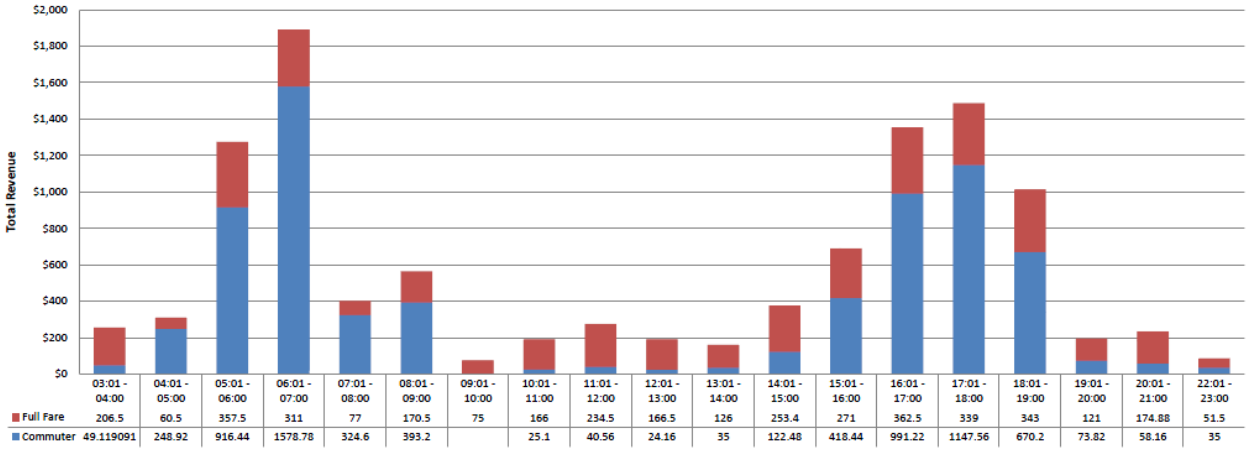
Figure 5.16 shows the average weekday ridership and service velocity by the southbound time of arrival in Boston for March 2013. The black line shows scheduled service velocity in miles per hour by time of day. As would be expected, service velocity is substantially higher for midday and evening trips. The red line shows average daily ridership for each scheduled trip. BX suffers due to traffic congestion on I-93 because its service velocity is lowest when demand for its service is highest.

Figure 5.16: Average Weekday Ridership and Service Velocity by Southbound Time of Arrival in Boston (March 2013)



Most peak users of the BX service are regular commuters as evidenced by their use of the discounted multi-ride commuter tickets. The off-peak riders are much more likely to travel using a full-fare, one-way ticket. Figure 5.17 shows the number of passengers per hour who use a multi-ride commuter ticket (blue) and the number who purchase full-fare, single-ride tickets.

Figure 5.17: Hourly BX Total Revenue Collected by Fare Type and Departure Time of Day



BX operates commuter service on a franchise from the State of New Hampshire and receives an annual subsidy. The subsidy is assessed each year based on operating revenue shortfalls. Its sister operation, Concord Coach, operates as an entirely private entity and does not receive operating support for its intercity service. Both services use buses purchased with financial assistance from the State of New Hampshire. All the park-and-ride lots in the corridor used by BX and Concord Coach were constructed and are owned by state or local governments.

5.3.2 Concord Coach

Formerly known as Concord Trailways, Concord Coach Lines, Inc., is an intercity bus company originally founded in 1967, and expanded in 1988 with the purchase of the Trailways franchise. Concord Coach Lines operates along the I-93 corridor with service from Berlin and Littleton, New Hampshire through Concord to Boston South Station and Logan Airport (see Table 5.8 for a summary of service). It also operates service in the I-95 corridor between Bangor, Maine and Boston. NHDOT tracks Concord Coach boardings at the Concord, New Hampshire bus station on Stickney Avenue. In 2012, ridership averaged approximately 150 passenger boardings per day.

Concord Coach operates a total of 13 northbound and 12 southbound trips per day between Concord, South Station, and Logan Airport in Boston. Two round trips per day operate between Concord and Littleton. One round trip per day operates between Concord and Berlin and a truncated weekend-only service operates between Concord and as far north as North Conway. BX tickets are cross-honored on all trips between Manchester, North Londonderry, Salem, and Boston.

Table 5.8: Concord Coach I-93 Bus Service

	Southbound Service	Northbound Service
Ridership	Not available	Not available
Peak Trips	4	5
Off-Peak Trips	8	8
Span of Service	5:00am-8:50pm	7:15am-11:20pm
Peak Headways	60 min	60 min
Off-Peak Headways	60-120 min	60-120 min

5.3.3 Massachusetts Bay Transportation Authority (MBTA)

MBTA operates four peak-period, weekday-only express bus services within the Study corridor along I-93 from Woburn, Burlington, and West Medford to Haymarket and State Street in downtown Boston. Together these four routes carry almost 2,000 weekday passenger trips (Table 5.9). These routes are subject to the same peak-period traffic congestion on I-93 that adversely impacts motorists and other express bus services.

Table 5.9: MBTA I-93 Bus Service

Route	Garage	Terminals	Weekday Boardings		
			Inbound	Outbound	Total
325	Charlestown	Elm St. – Haymarket Station	171	149	320
326	Charlestown	West Medford – Haymarket Station	227	207	434
352	Charlestown	Burlington – State Street	180	197	377
354	Fellsway	Woburn Line – State Street	365	427	792
Total			**943**	**980**	**1,923**

5.3.4 Merrimack Valley Regional Transit Authority (MVRTA)

The MVRTA Boston Commuter Bus provides four inbound trips in the morning and four outbound trips in the evening via I-93. These buses carry 257 passenger trips on a typical weekday and are subject to the same peak congestion that impacts other users of I-93.

5.3.5 Greyhound

Greyhound provides intercity service from Boston to Manchester, Concord, and points north and west. Four daily Montreal-bound trips depart from Boston, three of which stop at Manchester Airport, two in Manchester, and one in Concord. Of the four daily southbound trips from Montreal to Boston, one stops in Concord and Manchester, while all four stop at Manchester Airport. Greyhound also provides one trip per day between Boston, Nashua, Manchester, and Concord via Worcester and Leominster, Massachusetts.

5.3.6 Dartmouth Coach

Dartmouth Coach provides intercity service from New Hampshire's Upper Valley to Boston and New York City. It does not make any stops or provide any service to communities within the Study area.

5.3.7 Manchester Transit Authority (MTA)

The MTA provides bus service throughout Manchester and operates express service to Nashua and Concord. Thirteen routes provide scheduled service to Manchester and surrounding destinations. Two express routes provide service from downtown Manchester to Concord and from downtown Manchester to the Nashua Mall. Concord Express originally served the Manchester Airport, but that service was eliminated to low ridership.

5.3.8 Nashua Transit System (NTS)

The NTS comprises nine local routes that begin and end their trips at the downtown Transit Center behind City Hall. Each route operates 12-13 round trips per day on hourly headways.

5.3.9 Concord Area Transit (CAT)

The CAT operates three weekday routes serving the City of Concord and surrounding communities. Each route operates 12-13 hours per day.

5.3.10 Lowell Regional Transit Authority (LRTA)

The LRTA operates 12 local routes and one downtown shuttle serving the City of Lowell and the towns of Billerica, Burlington, Dracut, Chelmsford, Tewksbury, Tyngsborough, Westford, and Wilmington, Massachusetts. All 12 routes now operate on hourly headways. The downtown shuttle operates on 30-minute headways from 7:30am - 7:00pm.

6 Service Alternatives

The Study team held numerous meetings with a wide variety of stakeholders, including public officials from New Hampshire and Massachusetts, all regional public transportation providers, Amtrak, PAR, and the general public. The project Rationale derived from the process of assembling and evaluating information concerning existing and likely future travel conditions in the corridor. This research and consultation led the team to understand the opportunities and constraints it faced in framing alternatives for improved corridor public transport service. As the Study was jointly funded by the FRA and FTA, the range of alternatives considered and developed covered both bus and rail service options. Bus service options included modifications to the frequency and operating conditions of the existing BX commuter bus system. Rail service options included extensions of MBTA's Lowell Line service and options for intercity rail services that would overlay on the existing mix of passenger and freight rail services.

The most salient transport problem addressed in developing the alternatives was improving connections between southern New Hampshire and the regional core in downtown Boston. The principal travel obstacle in the corridor is the extreme peak-period highway congestion that slows Boston-bound travel to a 12 mph crawl for the final eight miles of a typical morning peak trip into the city.

The Study team consulted with MBTA, PAR, NHDOT, MassDOT, BX, and others to develop a set of two base, nine rail, and three bus service options for preliminary screening (Tables 6.1 and 6.2). Using preliminary estimates of cost, demand, and revenue, the Study team consulted with project stakeholders and the general public to screen the 12 initial build options down to seven intermediate options and then five final options (three rail, one bus, one no build) for refinement and more detailed analysis. This section introduces the 12 preliminary build options then reviews the intermediate and final options in more detail.

Table 6.1: Preliminary Rail Service Options

Options	Weekday Revenue Trains			Route Miles	Stations Served
	Nashua	Manchester	Concord		
No Build	0	0	0	26	8
Intercity Passenger Rail Options					
Intercity 8	8	8	8	73	6
Intercity 12	12	12	12	73	6
Intercity 18	18	18	18	73	6
Commuter and Regional Rail Options					
Concord Regional	30	8	8	73	13
Concord Commuter	26	22	18	73	13
Manchester Regional	34	16	0	56	12
Manchester Commuter	30	20	0	56	12
Nashua Commuter	34	0	0	39	10
Nashua Minimum	16	0	0	35	9

Table 6.2: Preliminary Bus Service Options

Options	Weekday Revenue Trips								Weekday Vehicle Miles	%& Increase in Weekday Vehicle Miles
	Manchester	N. Londonderry	Londonderry	Salem	Nashua	Tyngsborough	South Station	Logan Airport		
No Build	18	46	17	39	24	23	80	58	3,932	0%
Expanded Base	32	40	39	40	38	38	120	120	5,850	49%
Bus on Shoulder	18	46	17	39	24	23	80	58	3,932	0%
Expanded Bus on Shoulder	32	40	39	40	38	38	120	120	5,850	49%

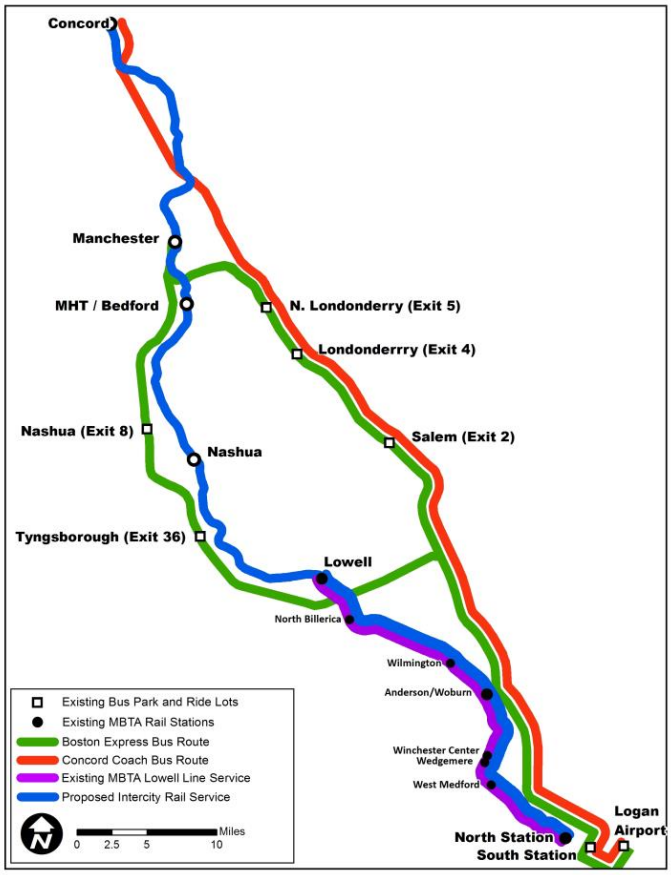
6.1 Preliminary Intercity Rail Service Options

The Study team devised a hierarchy of three conceptual options that could be operated as an independent intercity rail service that would extend 73 miles northward from North Station to Concord (Figure 6.1). These options are based on NHML historic and current physical attributes, the schedule of passenger services on the line, and general service parameters for Amtrak services in corridors of less than 150 miles. Each service would have the following characteristics:

- Operate independently of MBTA and Amtrak *Downeaster* passenger services already serving the route's southernmost 25 miles
- Require no upgrades to infrastructure south of Lowell
- Require upgrades to rail infrastructure north of Lowell

- Upgrade 48 miles of existing track to FRA Class 4 providing for maximum passenger train speeds of 70 mph, since no historic records show higher speeds along the route since its opening in the 1800s
- Establish Crown Street in Nashua as a passing point for northbound and southbound passenger trains (Intercity 12 and 18)
- Install one or more industrial sidings between Nashua and Concord allowing passenger trains to pass or meet freight trains
- Install a passing siding on the PAR main line west of North Chelmsford to reduce the need for trains to stand east of North Chelmsford on the route between Lowell and Nashua
- Install NORAC Rule 261 signals between Manchester and Concord (approximately 18 miles)
- Install MBTA Positive Train Control (PTC) protection

Figure 6.1: Intercity Rail Service Options



Services would stop at six passenger stations north of Boston. The distance and travel time to Boston for each station are listed in Table 6.3.

Table 6.3: Initial Preliminary Design Miles and Travel Time to Boston

Station	Miles to Boston	Time to Boston
Concord	73.3	1:36
Manchester	55.5	1:22
Bedford/MHT	50.1	1:09
Nashua	38.8	0:56
Lowell	25.5	0:38
Woburn	12.6	0:23

The projected travel times compare favorably with historic minimum travel times between Concord and Boston (see Table 6.4).

Table 6.4: Historic Minimum Concord-Boston Travel Times

	1910	1926	1945	1954
Travel Time	2:00	2:05	1:35	1:22
Average Speed (mph)	37	35	46	54

Source: Jacobs analysis of archived public timetables

6.1.1 Intercity 8

The eight-train-per-day Intercity 8 option would provide four daily round trips over the 73-mile route, stopping at five intermediate stations including the Manchester Airport (see the preliminary timetable in Table 6.5). The end-to-end trip time would be approximately 96 minutes. The service would entail 586 daily train miles. Presuming an average cost of $36 per train mile, Intercity 8 would cost approximately $7.7 million per year to operate.

Table 6.5: Intercity 8 Preliminary Timetable

380	382	384	386		Station	MP		381	383	385	387
6:38	10:38	14:53	19:53	Read Down	Concord, NH	73.3	Read Up	10:07	14:22	18:57	23:37
6:52	10:52	15:07	20:07		Manchester, NH	55.5		9:41	13:56	18:31	23:11
7:05	11:05	15:20	20:20		Bedford/MHT	50.1		9:33	13:48	18:23	23:03
7:18	11:18	15:33	20:33		Nashua	38.8		9:20	13:35	18:10	22:50
7:36	11:36	15:51	20:51		Lowell	25.5		9:02	13:17	17:52	22:32
7:52	11:52	16:07	21:07		Anderson/Woburn	12.6		8:46	13:01	17:36	22:16
8:15	12:15	16:30	21:30		North Station	0.0		8:30	12:45	17:20	22:00

The service could be extended with possible connections to private bus services for North Country destinations. No substantial changes in express bus service for commuting to Boston via US Route 3/Everett Turnpike or I-93 would be expected. Local bus service to the intercity rail stations could be offered, but would not be integral to the service design. The service would use a single four-car train set stored in Concord. A spare locomotive and a spare coach would also be required.

6.1.2 Intercity 12

The 12-train-per-day Intercity 12 option would operate six daily round trips (see the preliminary timetable in Table 6.6). The service would provide travelers in both New Hampshire and Massachusetts with more convenient morning northbound trips and evening southbound trips that would not be available with Intercity 8. The service would entail 880 daily train miles. Presuming an average cost of $36 per train mile, Intercity 12 would cost approximately $12 million per year to operate.

As with Intercity 8, the service could be extended with possible connections to private bus services for North Country destinations. No substantial changes in express bus service for commuting to Boston via US Route 3/Everett Turnpike or I-93 would be expected. Local bus service to the rail stations could be offered, but would not be integral to the service design. The service would use two four-car train sets. One would be stored in Concord and the other in Boston. A spare locomotive and one spare coach would also be required.

Table 6.6: Intercity 12 Preliminary Timetable

Southbound						
Train	**380**	**382**	**384**	**386**	**388**	**390**

6.1.3 Intercity 18

The 18-train-per-day Intercity 18 option would provide nine daily round trips (see the preliminary timetable in Table 6.7). This would constitute bi-hourly, bi-directional service 18 hours per day between Concord and Boston. It represents an upper limit on the density of intercity service that could be considered between Central New Hampshire and Downtown Boston. The service would entail 1,319 daily train miles. Presuming an average cost of $36 per train mile, Intercity 18 would cost approximately $17 million per year to operate. As with the other options, Intercity 18 could be extended with possible connections to private bus services for North Country destinations. No substantial changes in express bus service for commuting to Boston via US Route 3/Everett Turnpike or I-93 would be expected. Local bus service to the intercity rail stations could be offered, but would not be integral to the service design. Like Intercity 12, the service would use two four-car train sets. One would be stored in Concord and the other in Boston. A spare locomotive and one spare coach would also be required.

Table 6.7: Intercity 18 Preliminary Timetable

6.2 Preliminary Commuter Rail Options

Meetings with MassDOT and MBTA in the Spring of 2013 indicated a willingness to work with NHDOT on the provision of passenger service along the NHML from New Hampshire to North Station. This cooperation could come in the form of MBTA operation of trains into New Hampshire or the operation of intercity trains along the same route. It was stated that with the imminent relocation of the Spaulding Hospital immediately west of North Station that two new station tracks at the terminal would be opened providing capacity for one additional peak Amtrak train in each direction. MBTA would also be willing to extend its service into New Hampshire provided that the service extension was essentially transparent to existing MBTA passengers using services offered between Lowell and Boston and that the net cost of the service extension to Massachusetts taxpayers would be zero.

The “net cost of zero” would be achieved via a “Pilgrim Partnership” arrangement with NHDOT that would mimic successful rail service funding and operational arrangements between Rhode Island and Massachusetts that allow MBTA to offer passenger rail service into Rhode Island. The broad outline of the “Pilgrim Partnership” calls for the host state to provide MBTA with an ongoing flow of capital funds. The funds, much of which would be federal formula grants, would be spent at the MBTA’s prerogative on rolling stock and facilities necessary for its overall commuter rail operation. Some of the funded assets may be used for the interstate service, but none of the assets are dedicated or obligated to that service. With that capital funding in-place, MBTA would agree to operate trains into the neighboring state in exchange for the passenger revenue collected from out-of-state passengers. The funding host state would

be responsible for upkeep of the fixed infrastructure in its state and any fees charged by the host railway. The MBTA would then pay for management, training of crews, fuel, and maintenance of rolling stock.

The Study team devised a hierarchy of six conceptual rail services that could be operated as an extension of MBTA Lowell service northward into New Hampshire. These options were based on NHML historic and current physical attributes, the schedule of passenger services on the line, and parameters of MBTA's offer to operate the service as integral portion of its other services to and from North Station. Each service would have the following characteristics:

- Extend existing MBTA service into New Hampshire
- Be generally transparent to existing MBTA customers
- Have no impacts on existing Amtrak service between North Station and Maine
- Require no upgrades to infrastructure south of Lowell
- Require upgrades to rail infrastructure north of Lowell
    - Upgrades to existing track (up to 48 miles) to FRA Class 3 providing for maximum passenger train speeds of 60 mph
    - Installation of second main line track between North Chelmsford and downtown Nashua
    - Installation of at least one siding between Nashua and Bow allowing passenger trains to pass or meet freight trains serving this segment
    - Installation of NORAC Rule 261 signals between Manchester and Concord (approximately 18 miles)
    - Installation of MBTA PTC protection

Class 3 track was selected for the preliminary options to reduce costs. An upgrade to Class 4 would cost more for track upgrades and maintenance. The estimated difference in running times between Nashua and Lowell with an upgrade to Class 4 would be one minute. Class 4 track would cut approximately six minutes on the running time between Concord and Lowell. For one commuter rail option (Concord Commuter), the team used Class 4 speeds (up to 70 mph) to establish an economic harmony between the existing MBTA schedules and rolling stock and crew requirements.

The six conceptual commuter rail services are described below. The services would stop at up to five passenger stations north of Lowell. Table 6.8 lists the five stations with their distance to Boston and projected maximum and minimum travel times.

Table 6.8: Initial Preliminary Commuter Rail Designs: Miles and Minutes to Boston

Station	Miles to Boston	Maximum Travel Time to Boston	Minimum Travel Time to Boston
Concord	73.3	1:54	1:46
Manchester	55.5	1:32	1:25
Bedford/MHT	50.1	1:24	1:17
Downtown Nashua	38.8	1:14	1:02
Nashua South	35.5	1:08	0:54

6.2.1 Concord Regional Rail Service

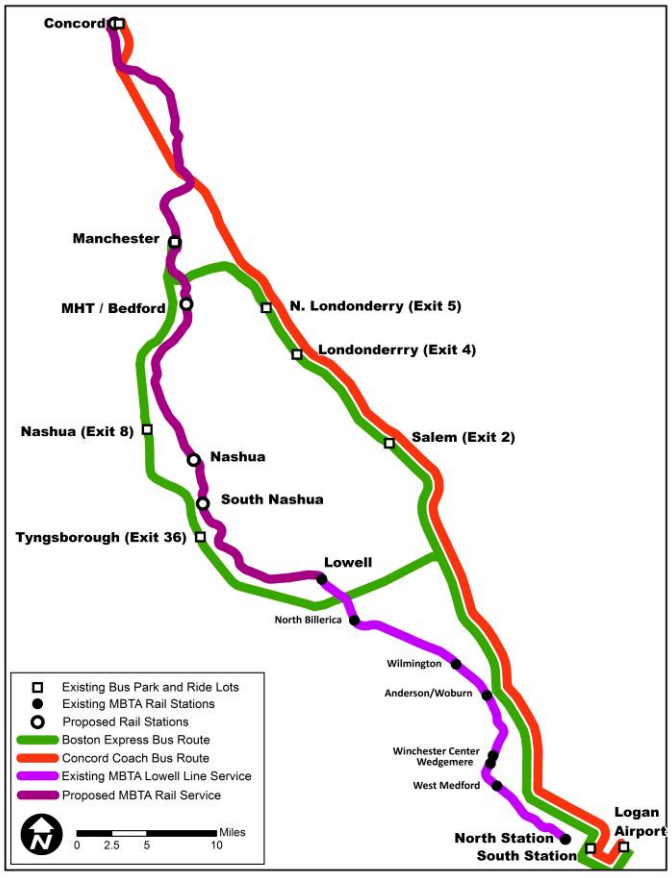
Concord Regional Rail provides a mix of commuter train service for Nashua with a lower frequency regional service provided for Manchester and Concord. The service adds six new stations to the line with eight weekday trains for Concord and Manchester and 30 weekday trains for Nashua. All MBTA deadhead trains are eliminated. A layover facility for one train set would be required in Concord and for three trains in the vicinity of Nashua. The service would require an additional train set conservatively estimated at seven coaches. Additional coaches on the other five train sets assigned to the service would be required to carry the new passengers onto the NHML services. Up to 12 coaches and one locomotive would be added to the MBTA's weekday line-up of equipment for one new seven-car train and five additional coaches on existing consists assigned to the service.

6.2.2 Concord Commuter Rail Service

Compared with Concord Regional, Concord Commuter provides a more ambitious LOS for Concord (and Manchester). It is the only commuter rail option that would require Class 4 track and would necessitate extensive track upgrades, with maximum speeds between Lowell and Concord restored to their historic maximum of 70 mph where possible. Like Concord Regional, it adds six new stations to the line, but provides 18 trains to Concord, 22 to Manchester and Bedford/Manchester Airport, and 26 trains to Nashua. Four MBTA train sets assigned to the line are stored overnight in the vicinity Concord.

Owing to the higher maximum speeds, the travel times from Concord, Manchester and Nashua would be somewhat shorter, approximately 105 minutes, 90 minutes, and 66 minutes respectively. The largest time savings resulting from the higher speeds is for

Figure 6.2: Concord Rail Service Options



the 73-mile trip to Concord. Like Concord Regional, the service would require an additional train set conservatively estimated at seven coaches. Up to 12 coaches and one locomotive would be added to the MBTA's weekday line up as in Concord Regional. Concord Regional and Concord Commuter Rail Service options are shown in Figure 6.2 above.

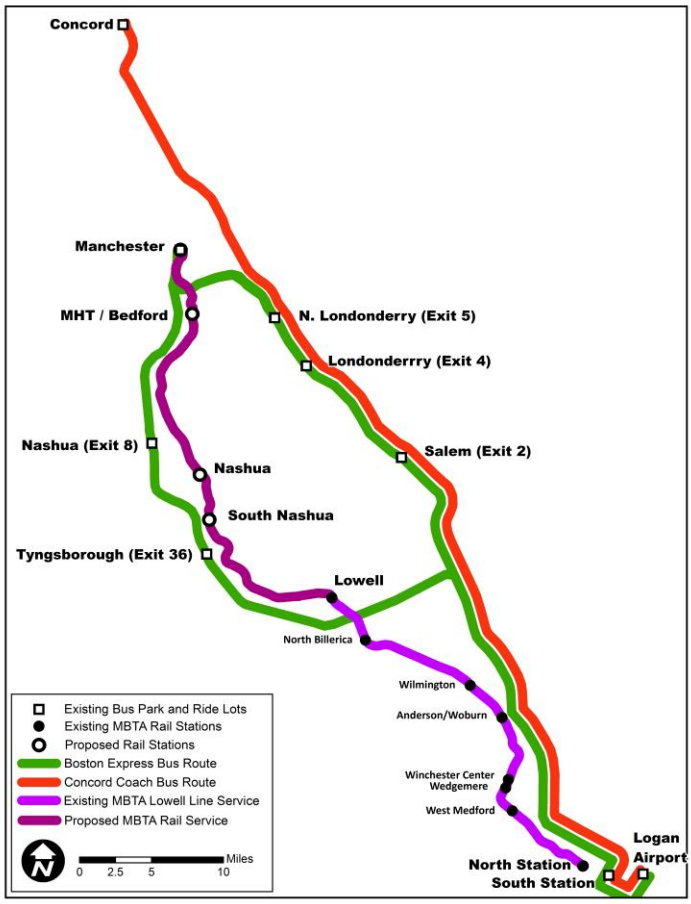
6.2.3 Manchester Regional Commuter Rail Service

Manchester Regional provides a mix of commuter train service for Nashua with a lower frequency regional service provided north to Manchester. MBTA service would be extended 30 miles to downtown Manchester. The service adds five new stations to the line with 16 weekday trains for Manchester and 34 for Nashua. As with Concord Regional and Concord Commuter, all MBTA deadhead trains are eliminated. A layover facility for four train sets would be constructed in the vicinity of Manchester. Up to 12 coaches and one locomotive would be added to the MBTA's weekday line-up of equipment.

6.2.4 Manchester Commuter Rail Service

Manchester Commuter provides more extensive service for Manchester compared with the Concord Regional, Concord Commuter, and Manchester Regional. As with Manchester Regional, MBTA service would be extended 30 miles to downtown Manchester. The service adds five new stations to the line with 20 weekday trains for Manchester and 30 for Nashua. As with the previous options, all MBTA deadhead trains are eliminated. As with Manchester Regional, a layover facility for four train sets would be constructed in the vicinity of Manchester. Also as with the previous options, up to 12 coaches and one locomotive would be added to the MBTA's weekday line-up. Manchester Commuter and Manchester Regional are shown in Figure 6.3.

Figure 6.3: Manchester Rail Service Options



6.2.5 Nashua Commuter Rail Service

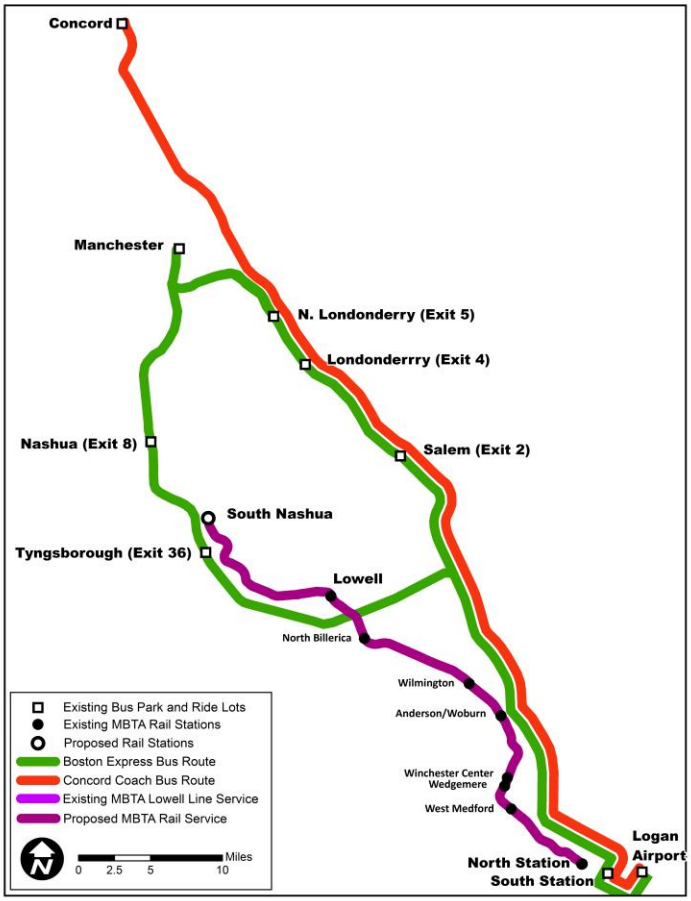
Nashua Commuter provides commuter train service to and from downtown Nashua with no rail service beyond to Manchester or Concord. It could be developed and operated as an interim service coordinated with bus service for Manchester and Concord until service is implemented further north. MBTA service would be extended 13 miles from Lowell to downtown Nashua. The service adds two new stations to the line with 34 weekday trains for Nashua. A layover facility for four train sets would be constructed in the vicinity of

Nashua. As with the other options, up to 12 coaches and one locomotive would be added to the MBTA's weekday line up.

6.2.6 *Nashua Minimum Commuter Rail Service*

Nashua Minimum provides a minimal peak-only commuter rail service to and from South Nashua with no rail service beyond Nashua to Manchester or Concord. It is specifically designed to minimize MBTA's operating cost of extending service to Nashua. Like Nashua Commuter, it could be developed and operated as an interim service coordinated with bus service while markets and finances for more New Hampshire options were given time to develop.

Figure 6.4: Nashua Rail Service Options



MBTA service would be extended 9.7 miles to the South Nashua station located at or immediately across the New Hampshire state line. The service adds one new station to the line with 16 weekday trains for Nashua. As with Nashua Commuter, a layover facility for four train sets would be constructed in the vicinity of South Nashua. Similar to the previous options, up to 13 coaches and one locomotive would be added to MBTA's weekday line-up of equipment. The South Nashua station would be located approximately at MP 35.2 in the vicinity of Pheasant Lane Mall or Spit Brook Road.

Nashua Minimum is proposed to provide service from Boston North Station to South Nashua during peak periods only and would travel only as far north as Lowell, Massachusetts during off-peak periods. The rail service could potentially be supplemented by a schedule of feeder buses that would extend the reach of off-peak trains north to South Nashua to ensure adequate mid-day mobility and travel options are available to daily commuters. Six inbound and six outbound buses could be provided throughout the day and could be operated with a single vehicle.

To schedule the feeder service with a single bus, the Study team decided to prioritize travel time for southbound passengers. Timetables developed by the team show that southbound trips are scheduled to provide five minutes for transfer from bus to rail. This will require that the bus portion of the trip is operated reliably to ensure that the connection to the train is made on time. Northbound trips will depart using the same bus and passengers will therefore wait approximately 15 minutes for the transfer

from rail to bus. This is due to the time required for crews to turn the train in Lowell. This longer transfer time built-in to the schedules will allow for any delays on outbound rail trips from Boston and ensure that transferring passengers are not left at the station in Lowell. Nashua Rail Service options are shown in Figure 6.4 above.

6.3 Preliminary Bus Service Options

Recognizing that any rail service would require a substantial investment in upgrading track and constructing support facilities, the Study team also developed options that could improve the frequency and/or travel time of corridor express and intercity bus service. Recognizing that peak-period bus service from New Hampshire to Boston is mired in the same crawling automobile traffic that slows travel for motorists, the Study team spent considerable time researching the potential benefits of offering Bus on Shoulder service along I-93 in Massachusetts. The team also developed options that would expand the frequency and directness of bus service between downtown Boston and southern New Hampshire. The mix of more and frequent service resulted in three bus service options for consideration plus the base (existing) service option, as summarized in Table 6.9.

Table 6.9: Preliminary Bus Service Options

Options	Weekday Revenue Trips								Weekday Vehicle Miles	%& Increase in Weekday Vehicle Miles
	Manchester	N. Londonderry	Londonderry	Salem	Nashua	Tyngsborough	South Station	Logan Airport		
Base	18	40	19	32	37	21	80	58	3,932	0%
Expanded Base	32	39	38	39	37	37	120	120	5,850	49%
Bus on Shoulder	18	40	19	32	37	21	80	58	3,932	0%
Expanded Bus on Shoulder	38	39	38	39	37	37	120	120	5,850	49%

This portion of the SDP describes how Bus on Shoulder could be developed to offer some peak travel time savings. It then goes on to summarize the three bus service investment options. Additional details on the preliminary bus options can be found in Appendix 4 to the AA Final Report (Task 4 Initial Conceptual Transit Alternatives).

6.3.1 Base Service (Existing Bus Service)

Base service currently offered in the corridor is used as a baseline to compare the performance of any proposed transit service expansion to existing conditions. It is assumed to include any planned improvements to the highway network that would be in-place by 2030, such as the NHDOT I-93 improvement project and various interchange and lane improvements within Massachusetts. This option also includes the existing park-and-ride lots throughout the corridor. It maintains the current express and intercity bus service between New Hampshire, South Station, and Logan Airport along I-93. It does not incorporate any expansion of corridor rail service, but includes the proposed commuter rail

extension to Plaistow, New Hampshire. Tables 6.10 and 6.11 list the number of weekday trips and scheduled travel times between the park-and-ride lots and the South Station bus terminal.

Table 6.10: Base Service Bus Trips

	Manchester	N. Londonderry (Exit 5)	Londonderry (Exit 4)	Salem (Exit 2)	Nashua (Exit 8)	Tyngsborough (Exit 35)	South Station	Logan Airport
SB Trips	8	21	7	20	12	11	42	31
NB Trips	10	25	10	19	12	12	38	27
Total	18	46	17	39	24	23	80	58

Table 6.11: Base Service Travel Times to/from South Station

		Manchester	N. Londonderry (Exit 5)	Londonderry (Exit 4)	Salem (Exit 2)	Nashua (Exit 8)	Tyngsborough (Exit 35)
Max	Off-Peak	2:15	1:40	1:50	1:20	1:45	1:30
	Peak	2:20	1:30	1:45	1:25	1:50	1:35
Min	Off-Peak	1:05	1:05	1:15	0:45	1:04	0:50
	Peak	1:40	1:05	1:00	0:45	1:00	1:05

6.3.2 Expanded Base

The Expanded Base option increases the frequency of bus service along the corridor by providing additional peak-period, point-to-point, non-stop trips from each New Hampshire park-and-ride lot to Boston's South Station. The service would add approximately 40 trips to the daily schedule, and would provide more frequent service to and from each existing park-and-ride lot. The additional service would require approximately 10 more vehicles and drivers. There are no transit priority measures proposed in this option that would aim to increase service velocities or decrease travel times.

Peak-period, point-to-point service would be provided between each park-and-ride lot and South Station at 30 minute headways, except for the Manchester service, which would be operated at 60 minute headways throughout the day. Hourly off-peak service would provide service to each park-and-ride lot within the I-93 or Route 3 corridors. Tables 6.12 and 6.13 list the number of weekday trips and scheduled travel times between the park-and-ride lots and the South Station bus terminal.

Table 6.12: Expanded Base Trips

	Manchester	N. Londonderry (Exit 5)	Londonderry (Exit 4)	Salem (Exit 2)	Nashua (Exit 8)	Tyngsborough (Exit 35)	South Station
SB Trips	16	20	19	20	18	18	60
NB Trips	16	20	20	20	20	20	60
Total	32	40	39	40	38	38	120

Table 6.13: Expanded Base Travel Times

		Manchester	N. Londonderry (Exit 5)	Londonderry (Exit 4)	Salem (Exit 2)	Nashua (Exit 8)	Tyngsborough (Exit 35)
Max	Off-Peak	2:15	1:40	1:50	1:20	1:45	1:30
	Peak	2:20	1:30	1:45	1:25	1:50	1:35
Min	Off-Peak	1:05	1:05	1:15	0:45	1:04	0:50
	Peak	1:40	1:05	1:00	0:45	1:00	1:05

6.3.3 Bus on Shoulder

Bus on Shoulder would not add any additional trips, but would provide faster, more reliable travel times between New Hampshire and South Station. The proposed timetables maintain the existing arrival and departure times at South Station and modify the departure and arrival times at New Hampshire park-and-ride lots based on possible estimated travel time savings. The service would not require any additional vehicles to operate the proposed schedule. It could potentially reduce vehicle requirements by allowing vehicles to operate more reliably so that they could provide multiple peak-period round trips. Tables 6.14 and 6.15 list the number of weekday trips and scheduled travel times between park-and-ride lots and the South Station bus terminal.

This option could potentially be combined with a viable passenger rail option or advanced as a Transportation Systems Management (TSM) approach or be implemented as a companion to a potential rail service improvement. A TSM is an FTA designation for an option that would contain a collection of low-cost transportation improvements that seek to mitigate congestion or enhance operational capacity of the existing transportation network.

Bus on Shoulder Service

Bus use of highway shoulders has been an operational practice in North America for over 20 years. This growing practice allows professional bus drivers the discretionary authority to drive within highway

shoulders to reduce travel times and increase the reliability of transit service. The long-standing history of Bus on Shoulder operations and the increasing number of communities pursuing such projects point to this practice's success in terms of both passenger and institutional benefits, and automobile driver acceptance. Many agencies have demonstrated that Bus on Shoulder can safely and cost-effectively improve transit service on congested roadways.

Highway shoulders, generally used as an emergency breakdown lane and for emergency response vehicles, can be easily adapted for bus use. The key design requirements are a minimum lane width of 10 feet (12 feet preferred), adequate shoulder pavement strength, drainage inlets level with roadway, and signage. Conflicts with pavement edge rumble strips and lateral obstructions adjacent to shoulders sometimes need to be addressed. The costs for these upgrades vary widely, but are modest compared with most highway widening and interchange reconstruction costs.[16]

Figure 6.5: Bus on Shoulder in Minneapolis

Two of the earliest and most extensive Bus on Shoulder networks are operated in Minneapolis (Figure 6.5) and Ottawa. Both systems have been in safe operation for more than 20 years. In Ottawa, buses can use the shoulders of limited access highways at any time with maximum allowable speeds of 62 mph (100 kmh). The more conservative Minneapolis system allows buses to use highway shoulders when the speed of general traffic drops below 35 mph. Buses on the shoulder may operate at speeds 15 mph faster than travel in other lanes, up to a maximum speed of 35 mph. The more liberal Ottawa approach is consistent with current general purpose vehicle use of highway shoulders on I-93 and I-95 in greater Boston where automobiles are allowed to travel at 65 mph in the shoulder during peak periods.

With more than 300 miles of Bus on Shoulder operations, the Twin Cities and Ottawa examples are the most extensive North American Bus on Shoulder networks. Many other communities have found this practice to be advantageous. As of 2012, transit buses were also operating on shoulders in Virginia, Maryland, Illinois, Washington, New Jersey, Georgia, Delaware, California, Florida, Kansas, North Carolina, Ohio, and Ontario.

[16] Martin, Peter C. (2006). *TCRP Synthesis 64*: *Bus Use of Shoulders, A Synthesis of Transit Practice*, Transportation Research Board, National Research Council, Washington D.C. 2006, 100 pp.

Locally, the MVPC and MassDOT are evaluating Bus on Shoulder operations for I-93 in Massachusetts. That study assumes that Bus on Shoulder service along I-93 would follow the Minnesota operating model of 35 mph maximum speeds between I-495 and the Leonard P. Zakim-Bunker Hill Bridge in Boston.

Benefits of Bus on Shoulder

The direct benefits of Bus on Shoulder include reduced travel times and increased service reliability. Bus on Shoulder allows bus operators to maintain travel speeds, even in the case of unexpected traffic conditions, in turn increasing transit service reliability. Not only are actual travel times reduced once buses are allowed to bypass congestion, but customers perceive even greater reductions in travel time. Since perceptions are a key determinant in travel-mode decisions, perceived travel time savings are a real catalyst for increased transit market share.

Safety

Despite the long history of Bus on Shoulder, communities considering new Bus on Shoulder systems are often concerned with potential safety impacts. These concerns often focus on the ability of buses to merge in and out of GP lanes around highway entrances and exits or vehicles stopped on the shoulder (disabled vehicles, tow trucks, emergency responders, etc.). Bus on Shoulder networks in operation, however, have proven that thoughtfully designed Bus on Shoulder operations are inherently safe.

In the Twin Cities area, approximately half of all bus routes operated by the region's two largest transit providers operate on corridors that have the option to use Bus on Shoulder at some point along the route. The number of accidents involving these buses is low considering the scope of Bus on Shoulder operations. During the initial 10 years, between 1991 and 2001, there were 200 Bus on Shoulder accidents. Since the Twin Cities Bus on Shoulder system averaged 90 miles over this period, the number of accidents can be expressed as 0.2 accidents per mile per year. Most accidents were minor scrapes or mirror clips. No injuries were reported. Since 2001, there has been one injury:[17] An automobile struck a Bus on Shoulder bus from the rear killing the automobile driver. After 15 years of operations, Minneapolis Metro Transit reserves only $7,000 per year for damages resulting from Bus on Shoulder-related accidents. In other words, Metro Transit currently budgets approximately $26 per mile, annually, for Bus on Shoulder-related damages and contingencies.

Travel on the shoulder is advantageous only under congested conditions when buses have an opportunity to bypass slow moving traffic. Because buses only operate on shoulders when traffic in GP lanes is slow, the potential for accidents, especially those causing injury, are low. Whether operating a bus or private automobile, drivers' ability to react to changing conditions is much greater at low speeds.

[17] State and Local Policy Program, Hubert H. Humphrey Institute of Public Affairs, University of Minnesota (June 2007). Bus-only Shoulders in the Twin Cities. Prepared for the FTA. Retrieved from http://www.hhh.umn.edu/img/assets/11475/Bus/Only/Shoulders/Report/FINAL.pdf

For example, merging around obstructions is relatively easy for both buses and slow-moving traffic on congested roadways.

Existing Conditions

I-93 in New Hampshire is currently undergoing reconstruction to add two GP lanes in each direction as a congestion mitigation measure. Travel is not currently permitted on the shoulders. I-93 in Massachusetts is three lanes in either direction between the state line and Exit 41 (Route 125) in Andover. South of Exit 41, an additional general travel lane is added in each direction.

Peak vehicles in Massachusetts have been allowed to travel at speeds for up to 65 mph along the shoulders of I-93 north of Exit 41 since 1999.[18] Traffic flow in the peak periods is facilitated by the use of the shoulder in the peak direction between 6:00am and 10:00am in the morning, and between 3:00pm and 7:00pm in the afternoon. Shoulder use is not currently permitted for use by transit vehicles or commercial buses. Permission to use the breakdown lane for full speed GP traffic operations was extended by the Federal Highway Administration (FHWA) as an interim measure until a fourth lane is added north of Exit 41.

Bus on Shoulder operations would preclude shoulder use for private automobiles so that some mitigating measure may be necessary if Bus on Shoulder were implemented on this portion of I-93 before it is widened in Massachusetts' Essex County. There are currently no funded Massachusetts plans to widen I-93 between the state line and Exit 41.

MassDOT is planning to reconstruct Exit 46 in Methuen. When complete, a short portion of the highway between the state line and Exit 41 will not have a breakdown lane creating a potential choke point for any Bus on Shoulder implementation north of the Merrimack River. Typical peak traffic operates at free flow conditions along this segment so the impact on Bus on Shoulder benefits at this location would be minimal.

As noted in earlier, BX scheduled morning peak travel times are as much as 45 minutes longer than off-peak travel times due to congestion along their route (see Table 6.16). Bus on Shoulder operations could reduce some, but not all, of this congestion-related delay from the bus schedules. The Study team estimated that travel time savings from a Minnesota-Style Bus on Shoulder operation would save as much as 12 minutes on typical day. On days where the impacts of traffic congestion are compounded by accidents or incidents, the savings would escalate to as much as 37 minutes based on estimates derived from the Study sample data.

[18] Use of the breakdown lane for travel in the peak periods was instituted in 1999 after Andover State Representative Barry Finegold brought legislators and officials from Massachusetts and New Hampshire together to discuss options to reduce congestion on I-93

Table 6.16: Estimated Bus on Shoulder Bus Travel Time Savings by Time of Day and Direction

	Arrival Time at Boston South Station	Morning Peak Southbound

	To NH State Line	0:10	0:19	0:18	0:29	0:25	0:20	0:13	

6.3.4 Expanded Bus on Shoulder

The Expanded Bus on Shoulder service option provides faster and more frequent service by combining the increased service of Expanded Base with Bus on Shoulder operations to improve reliability and service velocity. Like the Expanded Base option, the service would add approximately 40 trips to the schedule, but would provide more frequent service to and from each of the existing park-and-ride lots than the Bus on Shoulder option. The additional service would require approximately 10 more vehicles and drivers.

Peak-period, point-to-point service would be provided between each park-and-ride lot and Boston's South Station at 30-minute headways, except for Manchester service, which would be operated at 60-minute headways throughout the day. Hourly off-peak service would provide service to each park-and-ride lot within the I-93 or Route 3 corridors. Tables 6.17 and 6.18 list the number of weekday trips and scheduled travel times between the park-and-ride lots and the South Station bus terminal.

Table 6.17: Expanded Bus on Shoulder Trips

	Manchester	N. Londonderry (Exit 5)	Londonderry (Exit 4)	Salem (Exit 2)	Nashua (Exit 8)	Tyngsborough (Exit 35)	South Station
SB Trips	16	20	19	20	18	18	60
NB Trips	16	20	20	20	20	20	60
Total	32	40	39	40	38	38	120

Table 6.18: Expanded Bus on Shoulder Travel Times

	Peak	0:53	0:52	0:57	0:37	0:51	0:51

6.4 Multi-Modal Options

Throughout the Study process, representatives of New Hampshire's intercity bus operators (BX, Concord Coach, C&J, and Dartmouth Coach) have indicated a willingness to work with NHDOT on the continued provision of commuter bus service along the I-93 corridor from New Hampshire to South Station. The continuation or expansion of the existing BX bus service does not preclude the opportunity for a combined bus and rail option in a later Study phase. Here are three multi-modal alternatives suggested by stakeholders:

1. Rail in the Route 3 corridor with Bus on Shoulder in the I-93 corridor
2. Rail serving the North Station market with bus serving the South Station market
3. Rail service during peak commute hours and bus service during off-peak hours

The intercity bus operators are very supportive of implementing a Bus on Shoulder strategy on I-93, and the co-location or sharing of station and park-and-ride facilities between the various modes.

6.5 Screening Preliminary Alternatives[19]

The Study team developed preliminary estimates of ridership, operating costs, capital costs along with land use, economic development, and environmental impacts of the nine rail and three bus alternatives to screen the alternatives down to a more manageable number for final evaluation. The team's recommendations were reviewed with all stakeholders, including the FRA and FTA as well as the general public, before being finalized. Table 6.19 shows the basic performance metrics calculated for each alternative.

[19] For more information on preliminary screening, see Appendix 5 to the Capitol Corridor AA Final Report (Task 5 Preliminary Evaluation of Conceptual Alternatives and Recommended Alternatives for Detailed Evaluation)

Table 6.19: Preliminary Estimates of Basic Economic Performance Metrics for Preliminary Alternatives

	Typical Weekday NH Passengers	Required Capital Expenditure (In Millions, 2014$)	Annual Operating Cost (In Millions, 2009$ for commuter rail, 2012$ for intercity rail and bus)	Annual Incremental Passenger Revenue (In Millions, 2014$)	Net Operating Cost (In Millions, 2012$)
Intercity 8	1,460	$162	$7.7	$3.5	$4.2
Intercity 12	1,720	$174	$11.6	$4.1	$7.45
Intercity 18	2,040	$174	$17.3	$4.9	$12.4
Concord Regional	2,700	$226	$11.1	$6.1	$5.0
Concord Commuter	3,020	$206	$13.3	$7.1	$6.1
Manchester Regional	3,120	$164	$9.7	$7.2	$2.5
Manchester Commuter	3,060	$164	$9.9	$7.1	$2.8
Nashua Commuter	2,040	$124	$6.8	$4.2	$2.6
Nashua Minimum	1,480	$124	$5.2	$2.7	$2.4
Expanded Base	346	$6	$3.0	$0.8	$2.2
Bus on Shoulder	692	$7	$0.0	$1.7	$0.0
Expanded Bus on Shoulder	1,038	$14	$3.0	$2.5	$0.5

After extensive consultation primarily focusing on the fiscal constraints faced by the State of New Hampshire, seven intermediate alternatives (three rail, three bus, and a No Build option) were selected for more detailed evaluation (see Table 6.20). The two commuter rail options with the lowest potential net operating cost, the one intercity rail option with the lowest preliminary net operating cost, and the three low-cost bus alternatives were recommended for refinement and detailed evaluation, as was the No Build Option.

Table 6.20: Intermediate Service Options Selected for Detailed Evaluation

Service Option	Required Capital Expenditure (In Millions, 2014$)	Net Operating Cost (In Millions, 2012$)
Intercity 8	$162	$3.6
Manchester Regional Commuter Rail	$164	$2.5
Nashua Minimum Commuter Rail	$124	$2.4
Expanded Base	$6	$2.2
Bus on Shoulder	$7	$0.0
Expanded Bus on Shoulder	$14	$0.5

The Intercity 8 alternative was selected from the three intercity rail service options because of its low net operating cost and reasonable mobility benefit perspectives. As shown in Table 6.21, the number of additional riders attracted by more frequent service with Intercity 12 and 18 did not keep pace with the additional forecasted capital and operations costs.

Table 6.21: Intercity Service Riders versus Cost

	Typical Weekday NH Passengers	Net Operating Cost (In Millions, 2012$)
Intercity 8	1,460	$3.6
Intercity 12	1,720	$6.9
Intercity 18	2,040	$11.8

6.6 Screening Intermediate Alternatives[20]

This section describes screening of the seven Intermediate alternatives (including No Build) with special emphasis on the preferred intercity and commuter rail alternatives (Table 6.22). Among the most salient of the refinements was resolution concerning disposition of express bus services should any of the rail service options be implemented. The seven intermediate alternatives are discussed in detail below.

Table 6.22: Intermediate Service Alternatives

Intercity 8	▪ Four daily intercity passenger rail round trips between Concord, NH and Boston, MA making intermediate stops at Manchester, Bedford/Manchester Airport, Nashua Crown Street, and Lowell and Woburn, MA ▪ Base BX service is retained
Manchester Regional Commuter Rail	▪ Extends MBTA commuter rail service north from Lowell, MA to Manchester, NH with intermediate stops at South Nashua, Nashua Crown Street, and Bedford/Manchester Airport ▪ BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained ▪ BX Route 3 service to Manchester, Nashua, Tyngsborough is retained
Nashua Minimum Commuter Rail	▪ Extends MBTA commuter service north from Lowell, MA to Manchester, NH with an intermediate stop at South Nashua, NH ▪ BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained ▪ BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained
Expanded Base	▪ New Hampshire's BX bus service is increased from current 80 buses per day to 120 buses per day ▪ All peak buses run direct and non-stop between each New Hampshire park-and-ride lot and Boston South Station with service every 30 minutes ▪ Each park-and-ride lot sees hourly off-peak service making intermediate stops at each New Hampshire park-and-ride lot ▪ No changes to existing passenger rail services
Bus on Shoulder	▪ Existing BX bus service of 80 daily trips is permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes ▪ Savings of 8 to 12 minutes predicted during the morning peak period ▪ No significant travel time savings predicted during the afternoon peak period
Expanded Bus on Shoulder	▪ Expanded Bus service of 120 daily trips is permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes ▪ Savings of 8 to 12 minutes predicted during the morning peak period ▪ No significant travel time savings predicted during the afternoon peak period

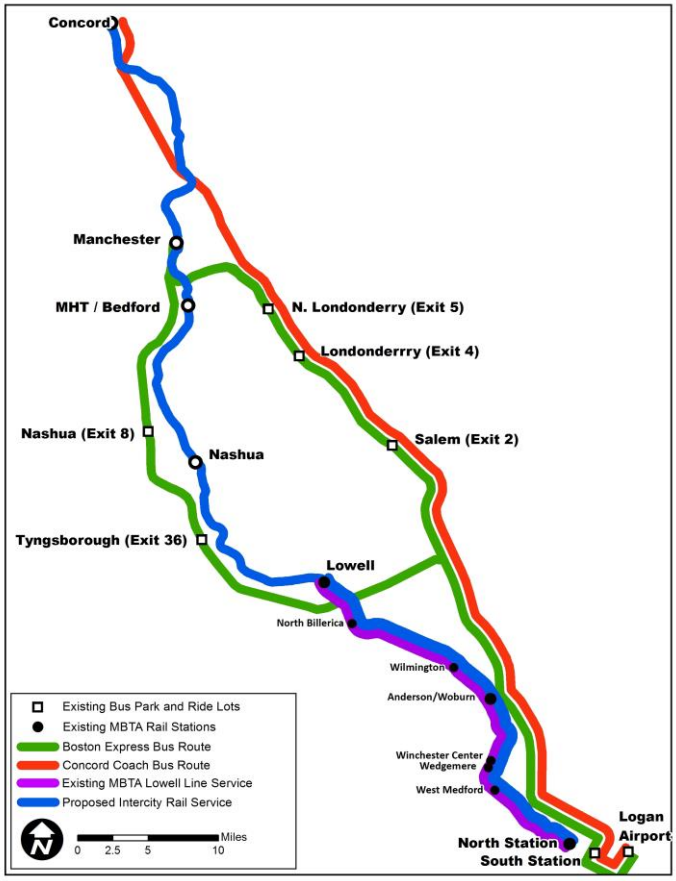
[20] For more information on the intermediate rail and bus alternatives, see Appendix 7 of the Capitol Corridor AA Final Report

6.6.1 *Intercity 8*

- Four daily intercity passenger rail round trips between Concord, New Hampshire and Boston, Massachusetts making intermediate stops at Manchester, Bedford/Manchester Airport, Nashua Crown Street, and Lowell and Woburn, Massachusetts
- BX Route 3 service to Nashua and Tyngsborough and BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained

The eight-train-per-day Intercity 8 rail option would provide four daily round trips over the 73-mile route stopping at five intermediate stations (see Figure 6.6). Intercity rail service would operate much like Amtrak's *Downeaster* service between Boston and Brunswick, Maine. The Intercity 8 option could be operated by Amtrak or the MBTA or contracted to a third-party service provider.

Figure 6.6: Intercity 8 Rail Service



The end-to-end trip time would be approximately 96 minutes and the service would operate 586 daily train miles. A timetable for the proposed service is shown in Table 6.23. Presuming an average cost of $36 per train mile, the Intercity 8 option would cost approximately $7.7 million per year to operate.

The service would provide connections in Concord to private bus services for North Country destinations. No changes are proposed to express bus service for commuting to Boston via I-93 or Route 3. Local bus service to the intercity rail stations could be offered, but would not be integral to the service design. A BX/Concord Coach/intercity rail fare integration scheme similar to that used by the *Downeaster* at Portland, Maine could be employed at the Concord and Manchester stations that would be shared by both intercity rail and coach bus services.

Anticipated ridership responses to the service initiative would include new riders attracted to the intercity rail service. It is anticipated that few current MBTA passengers living in New Hampshire would shift from using MBTA Lowell and North Billerica Stations to the new intercity rail service. Some BX and Concord Coach customers may shift to intercity rail service from Nashua, Manchester, and Concord. The overall increase in the quality and frequency of transit options to Manchester and Concord may stimulate bus ridership as has been observed at the shared terminal in Portland, Maine.

Table 6.23: Proposed Intercity 8 Timetable

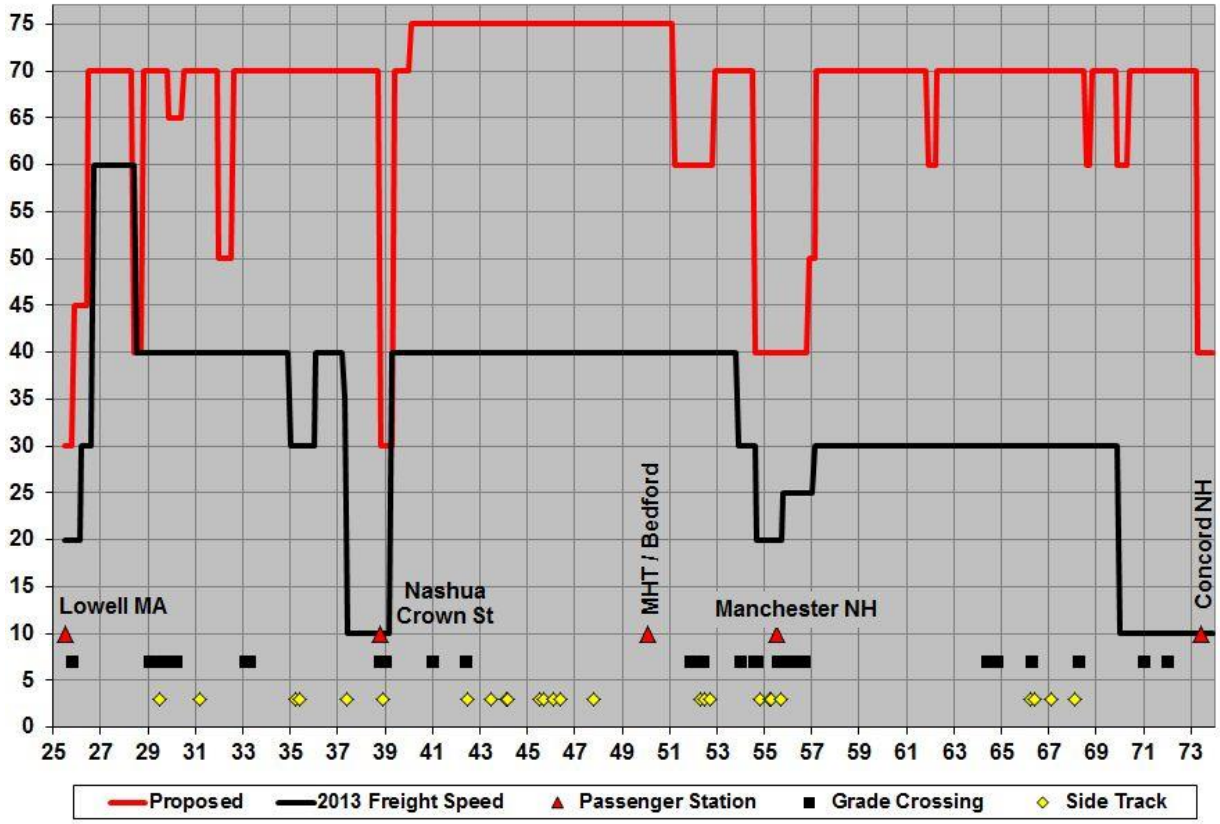
380	382	384	386		Station	MP		381	383	385	387
6:41	10:41	14:56	19:56	Read Down	**Concord NH**	73.3	Read Up	10:05	14:20	18:55	23:35
6:54	10:54	15:09	20:09		**Manchester NH**	55.5		9:39	13:54	18:29	23:09
7:07	11:07	15:22	20:22		**Bedford/MHT**	50.1		9:31	13:46	18:21	23:01
7:20	11:20	15:35	20:35		**Nashua**	38.8		9:18	13:33	18:08	22:48
7:36	11:36	15:51	20:51		**Lowell**	25.5		9:02	13:17	17:52	22:32
7:52	11:52	16:07	21:07		**Anderson/ Woburn**	12.6		8:46	13:01	17:36	22:16
8:15	12:15	16:30	21:30		**North Station**	0.0		8:30	12:45	17:20	22:00

No improvements would be required south of MBTA's Lowell Gallagher Terminal. North of Lowell the railroad would be upgraded to permit safe, reliable operation of eight daily passenger trains at speeds of up to 75 mph. Recommended upgrades to track, bridges, crossings, and signals are summarized below.

Intercity 8 would require more extensive infrastructure upgrades than the commuter rail options as it is approximately 18 miles longer than the Manchester Regional Commuter Rail service. The service would also operate at higher maximum speeds; up to 75 mph between Manchester Airport and Nashua and 70 mph at many other locations (see Figure 6.7).

Unlike the Manchester Regional and Nashua Minimum Commuter Rail options, no double track would be required between North Chelmsford (MP 28.5) and the southern end of the Tyngsborough Curve (MP 32). Industrial sidings would be created at three key areas of freight activity in Nashua and Merrimack to eliminate conflicts between local freight deliveries and through passenger trains. At these locations the existing main line track would be retained as an industrial siding with an entirely new parallel main line track constructed in the same alignment for use by through trains. Adding a second track would be straightforward as the railway was once entirely double tracked with the double-track bed still largely intact.

Figure 6.7: Proposed Maximum Passenger Speeds



Four new passenger stations would be constructed (see Table 6.24). They would be a mix of high-level platforms and low-level platforms with "mini-high" platforms for handicapped accessibility. The platforms at Nashua and Manchester would be less complex than for the commuter rail options because no intercity trains would turn from northbound to southbound at these stations.

Table 6.24: Intercity 8 Passenger Station Development Plan

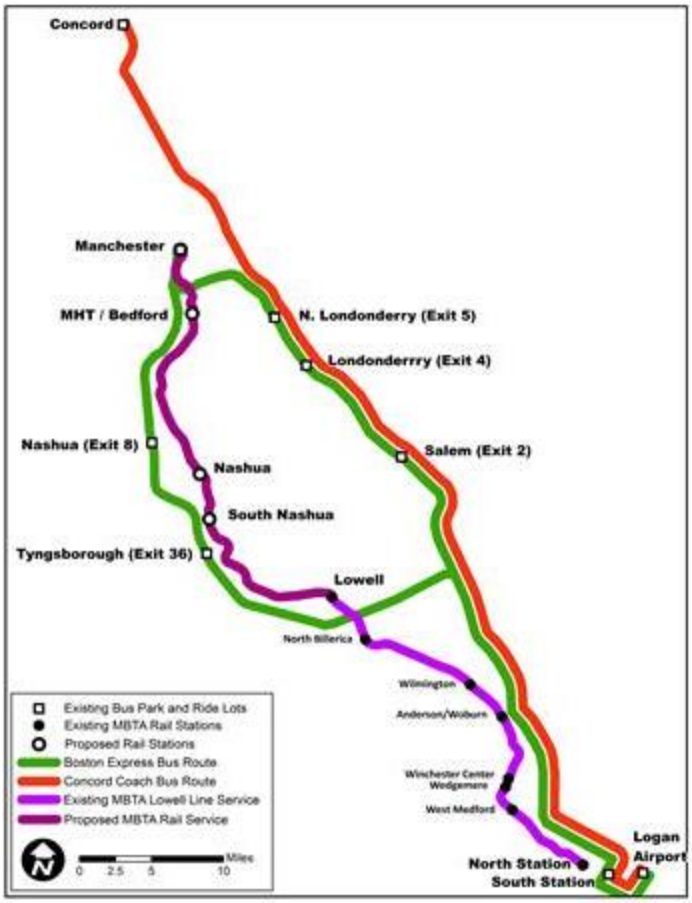
Station	MP	Comments
Concord	73.3	Single high-level platform on the stub end terminal track east of the main line
Manchester	55.5	Single low-level platform with mini-high to the east of the single main line track
Bedford/MHT	50.1	Single low-level platform with mini-high to the west of the single main line track
Nashua	38.8	Single low-level platform with mini-high to the west of the single main line track

6.6.2 Manchester Regional Commuter Rail

- Extends MBTA commuter rail service north from Lowell, Massachusetts to Manchester, New Hampshire with intermediate stops at South Nashua, Nashua Crown Street, and Bedford/Manchester Airport
- BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained
- BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained

The Manchester Regional Commuter Rail option would extend MBTA service 30 miles north from Lowell to downtown Manchester. The service initiative would provide all day commuter rail service between Boston and Nashua with a lower frequency regional service provided north to Manchester (see Figure 6.8). The service adds four new stations to the line with 16 weekday trains for Manchester and 34 weekday trains for Nashua. All existing MBTA deadhead trains on the Lowell Line would be eliminated.

Figure 6.8: Proposed Manchester Regional Commuter Rail and Bus Service Configuration



No improvements would be required south of Lowell's Gallagher MBTA Terminal. North of Lowell the railroad would be upgraded to permit safe, reliable operation of passenger trains at speeds of up to 60 mph. A layover facility for four train sets would be constructed in the vicinity of Manchester. Up to six coaches and one locomotive would be added to the MBTA's weekday equipment line-up. The number of weekday MBTA train miles operated on the line would increase 42 percent to 2,068. Six MBTA trains would be marginally adjusted with most changes required on light ridership reverse peak trains. The number of affected passengers would be 520 (3.9 percent) of 13,382 weekday riders. The total effect would be 10,202 passenger minutes of change (2.4 percent) out of 430,954 total daily passenger minutes of travel.

Ridership response to this service initiative is anticipated to include new riders attracted to rail service provided to the proposed New Hampshire stations. It is assumed that some current MBTA rail passengers living in New Hampshire would shift to these new stations from the existing MBTA Lowell and North Billerica Stations. Ridership impacts on the BX I-93 main line services to Londonderry and North Londonderry and Salem would be likely negligible.

Five new passenger stations – a mix of high-level and low-level platforms with MBTA mini-high platforms for handicapped accessibility – would be would be constructed (see Table 6.25). High-level platforms would be preferred at all locations. A low-level with mini-high platform approach would be employed where no path was available for PAR freight trains to avoid using the platform track to ensure a clear route for wide freight loads.

Table 6.25: Manchester Regional Commuter Rail Passenger Station Development Plan

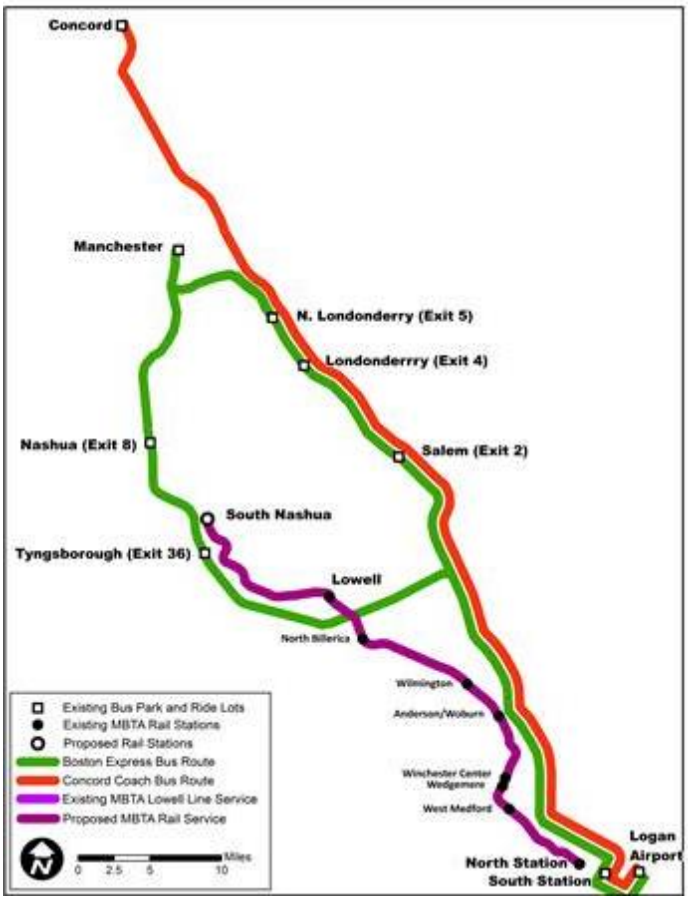
Station	MP	Type	Comments
Manchester	55.5	High-Level	Single high-level platform to the east of the eastern main line track
Bedford/MHT	50.1	Low-Level	Single low-level platform with mini-high to the west of the single main line track
Nashua	38.8	High-Level	Single island high-level platform between two main line tracks; oversize freight would run around platform using yard tracks
South Nashua	35.5	Low-Level	Single low-level platform with mini-high to the west of the single main line track

6.6.3 Nashua Minimum Commuter Rail

- Extends MBTA commuter service north from Lowell, Massachusetts to South Nashua, New Hampshire BX Route 3 service to Nashua and Tyngsborough is retained
- BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained

The Nashua Minimum Commuter Rail service option provides a minimal peak-period-only commuter rail service to and from South Nashua with no rail service further north to Manchester or Concord (Figure 6.9). It is specifically designed to minimize the MBTA operating cost of extending service to Nashua. It could be developed and operated as an interim service coordinated with bus service while markets and finances for further New Hampshire service were given time to develop.

Figure 6.9: Proposed Nashua Minimum Commuter Rail and Bus Service Configuration



MBTA service would be extended 13.5 miles north from Lowell to the South Nashua Station. The service adds one new station to the line with 20 weekday trains for South Nashua. A layover facility for four train sets would be constructed in the vicinity of South Nashua. No additional coaches or locomotives would need to be added to the MBTA's weekday line up of equipment.

The number of weekday MBTA train miles operated on the line would increase only three percent to 1,496. Schedules for several MBTA trains would be marginally adjusted with most changes required on light ridership reverse peak trains. The number of affected passengers would be 876 (6.5 percent) of 13,382 weekday riders. The total effect would be 9,846 passenger minutes of change (2.3 percent) out of 430,954 total daily passenger minutes of travel.

Optional midday and early evening feeder bus service would provide connecting service to fill out a complete schedule of services. Three midday and two early evening bus round trips linking South Nashua with the Lowell MBTA train station could supplement the peak-only rail service. BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem would be retained, as would Route 3 service to Nashua and Tyngsborough. Ridership response to this service initiative is anticipated to include new riders attracted to rail service provided to the proposed new station. It is assumed that some current MBTA rail passengers living in New Hampshire would shift to this new station from the existing MBTA Lowell and North Billerica Stations. It is also anticipated that many or most passengers from BX Route 3 service would shift to the commuter railroad potentially allowing for the elimination of that service. Ridership impacts on the BX I-93 main line services to Londonderry and North Londonderry and Salem would be likely negligible.

One new passenger station with a low-level platform would be constructed for the Nashua Minimum Commuter Rail option (see Table 6.26).

MBTA mini-high platform would be located at the north end of the station for handicapped accessibility.

Table 6.26: Nashua Minimum Commuter Rail Passenger Station Development Plan

Station	MP	Comments
South Nashua	35.5	Single low-level platform with mini-high platform to the west of the single main line track

6.6.4 Expanded Base

- New Hampshire's BX bus service is increased from current 80 buses per day to 120 buses per day
- All peak buses run direct and non-stop between each New Hampshire park-and-ride lot and Boston South Station with service every 30 minutes
- Each park-and-ride lot sees hourly off-peak (but not direct) service
- No changes to existing passenger rail services

The Expanded Base option (Figure 6.10) increases transit service frequency and directness within the Study Corridor by providing peak-period, point-to-point, non-stop trips from each of the New Hampshire park-and-ride lots to points within downtown Boston (southbound trips only), South Station, and Logan Airport. The service would add

Figure 6.10: Existing Study Corridor Bus and Rail Services

approximately 40 trips to the schedule and would require approximately 16 additional vehicles. There are no transit priority measures proposed in this option that would result in increased service velocities or decreased travel times.

Peak-period, point-to-point service would be provided at 30-minute headways, except for the Manchester service, which operates at 60-minute headways throughout the day. Hourly off-peak service would provide non-point-to-point service between each park-and-ride lot within the I-93 or Route 3 corridors and Boston South Station and Logan Airport without circulating through downtown Boston. A timetable for the proposed service is included in Index A at the end of this Section 1. Anticipated ridership response to this service initiative would include increased ridership at all BX park-and-ride lots and some possible reduction of ridership on MBTA commuter rail service from Lowell and, perhaps, North Billerica, Massachusetts.

6.6.5 Bus on Shoulder

- Existing BX bus service of 80 daily trips is permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes
- Savings of eight to 12 minutes predicted during the morning peak period
- Savings of up to five minutes predicted during the afternoon peak period

The Bus on Shoulder option provides faster peak-period service by permitting buses to operate within the I-93 shoulder south of I-495 to bypass peak congestion in Massachusetts. Typical southbound morning peak-period savings would be eight to 12 minutes depending upon arrival time. Typical northbound afternoon peak-period savings would be approximately five minutes. The option would not add any additional trips or operate in a point-to-point manner, but would provide faster, more reliable peak travel times. The proposed schedules maintain the existing arrival and departure times at South Station and modify the departure and arrival times at New Hampshire park-and-ride lots based on the estimated travel time savings resulting from Bus on Shoulder operation. The service would not require any additional vehicles to operate the proposed schedule. The timetable (see Index A at the end of this Section 1) prepared for this analysis reflects time savings estimated using a variety of sources. Ridership response to the service initiative is anticipated to include increased ridership at all BX park-and-ride lots and some possible reduction of ridership on MBTA commuter rail service from Lowell and perhaps North Billerica.

6.6.6 Expanded Bus on Shoulder

- 120 daily trips permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes
- Savings of eight to 12 minutes predicted during the morning peak period
- Savings of up to five minutes predicted during the afternoon peak period

The Expanded Bus on Shoulder option merges the increased frequency and directness of the Expanded Base option with the peak-period congestion bypass feature of the Bus on Shoulder option. It would offer faster and more direct peak service with more frequent off-peak service to all New Hampshire park-and-ride lots. The timetable prepared for this analysis merges the Bus on Shoulder and Expanded Base service concepts and can be found in Index A at the end of this Section 1. Ridership response to this

service initiative is anticipated to include increased ridership at all park-and-ride lots and some possible reduction of ridership on MBTA commuter rail service from Lowell and, perhaps, North Billerica.

6.7 Screening Intermediate Alternatives[21]

In refining and then screening the various service options, the Study team coordinated extensively with the FRA, FTA, MBTA, MVRTA, PAR, and BX regarding the alternatives' design and necessary infrastructure and rolling stock investments. Schedules, stringline diagrams, and corresponding track configuration diagrams were prepared for each rail option. Schedules and equipment rosters were prepared for the bus options.

Each of the rail options that were evaluated during the screening of intermediate alternatives exhibited a range of costs and benefits that were further refined for consideration by stakeholders and decision-makers. The Expanded Base and Expanded Bus on Shoulder options were eliminated from further evaluation. The Expanded Base option would result in the highest net operating cost and would attract the fewest new passengers of the three bus options. The Expanded Bus on Shoulder options would generate the greatest mobility benefits of the three bus options, but would do so at more than twice the capital cost of the Bus on Shoulder option.

From this information the Study team was able to make more detailed and accurate estimates of costs for each rail and bus service option. Another round of ridership forecasts was prepared using more sophisticated forecasting techniques. Separate models were used for the intercity rail, commuter rail, and express bus options. Amtrak's ridership forecasting team prepared the patronage forecasts for the Intercity 8 option. Each key economic performance metrics and assumptions are described in Table 6.27 and final estimates of cost and demand are summarized in 6.28.

[21] For more information on the intermediate alternatives, see Appendix 7 to the AA Final Report

Table 6.27: Key Economic Performance Metrics and Assumptions

Economic Performance Metric	Evaluation Assumptions
New NH Transit Passenger Trips	Includes all new transit trips originating in New Hampshire including rail trips diverted from Lowell to Nashua and any changes in BX ridership
New Corridor Transit Passenger Miles	Includes all transit trip miles made by passenger rail and BX; reflects downward adjustments in BX passenger miles for options where BX service is reduced or eliminated
Total Project Value (In Millions, 2014$)	Includes cost of all necessary infrastructure investment (e.g., railroad improvements, stations, rail yards, and bus shoulder lanes), the value of any necessary rolling stock (buses or trains), and the prorated value of MBTA's 37-mile Nashua to Concord trackage rights based on the option's length in New Hampshire; Intercity 8 would use Amtrak's statutory trackage right, not rights acquired by MBTA
NH Costs after Federal Grants and MA Contributions (Conservative Case)	Assumes that MBTA contributes rolling stock and trackage rights to the project, but does not contribute to the cost of infrastructure improvements north of Lowell; also assumes FTA does not consider MBTA contribution of rolling stock or trackage rights as contributing to eligible project value; consequently, the 50% FTA grant would cover half of the infrastructure investment; also assumes that FRA would fund half of the overall project value for Intercity 8 and that no federal capital funding would be available for the bus options
Annual Operating Cost (In Millions, 2012$)	Updated preliminary cost estimates for commuter rail options; final estimates for intercity and bus options; assumes weekday-only operation for commuter rail and bus services; intercity service would operate 365 days per year
Net Operating Cost (In Millions, 2012$)	Annual operating costs minus forecast passenger revenue and federal formula funds; FTA fixed-guideway formula funding is distributed for commuter rail service, but not for bus or intercity rail programs
Annual NH Debt Service	Assumes that NH share of project cost would be retired with 20-year bonds at 5% annual interest
NH Annual Total Cost	Sum of Net Operating Cost and Annual Debt service
NH Annual Cost Per New Passenger Mile	Shows NH annual cost divided by new annual transit passenger miles
NH Annual Cost per New NH Rider	Shows NH annual cost divided by new annual NH transit passengers

Table 6.28: Forecasts for Passenger Demand, Capital Cost, Operating Cost (In Millions), and Economic Metrics

Metrics	Intercity 8	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Bus on Shoulder
New NH Transit Passenger Trips	946	2,568	670	48
New Corridor Transit Passenger Miles	48,853	90,506	5,542	2,112
Forecast Capital Cost (In Millions, 2014$)	$256	$246	$120	$7
NH Costs after Federal Grants and MA Contributions (Pessimistic Case)	$128	$97	$49	$1
Annual Operating Cost (In Millions, 2012$)	$7.7	$11	$4	$0
Net Operating Cost (In Millions, 2012$)	$5	$2	$2	$0
Annual NH Debt Service (In Millions, 2012$)	$10	$8	$4	$1
NH Annual Total Cost (Debt Service and Operating Deficit) (In Millions, 2012$)	$15	$9	$6	$1
NH Annual Cost Per New Passenger Mile	$1.19	$0.41	$3.89	$1.11
NH Annual Cost per New NH Rider	$61	$14	$32	$49

Review of the forecast performance indicates that the Manchester Regional Commuter Rail, while expensive from a capital and operating cost perspective, would generate the greatest mobility benefits and the lowest unit costs per passenger mile and per passenger. The Bus on Shoulder option would be relatively inexpensive, but would generate limited mobility benefits with resulting medium-to-high unit costs per passenger and per passenger mile. Intercity 8 would be slight more expensive to construct than the Manchester Regional Commuter Rail; it would also attract fewer passengers and fewer passenger miles, resulting in a reduced operating efficiency. Nashua Minimum Commuter Rail would be half as expensive as the other rail options, but would attract many fewer passengers, resulting in relatively unattractive measures of efficiency.

7 Market Analysis

This section describes the methods and findings of the project's market analyses and patronage forecasts for the intercity rail options. Two sets of forecasts were prepared. The first set, prepared in 2013, supported preliminary analyses and screening. A second, more detailed set of forecasts was prepared for each of the final options, including the Intercity 8 option.

7.1 Ridership Forecasting[22]

Preliminary forecasts for Capitol Corridor rail service options were prepared using FTA's Aggregate Rail Ridership Forecasting Model 2.0 (ARRF2). Since the proposed service was only 73 miles long (shorter than some commuter rail lines in New York, Florida, and California), it was decided that the ARRF2 model would provide reasonable first estimates of potential ridership for both the commuter and intercity rail options. These first forecasts were for initial screening purposes. After initial screening, more robust forecasts were developed in consultation with FRA and FTA.

7.1.1 ARRF2 Model Limitations

The ARRF2 model is intended to develop order-of-magnitude estimates of rail ridership. The results presented in the preliminary estimates are considered to have "sketch planning" levels of accuracy sufficient for preliminary screening purposes.

- The ARRF2 model produces daily ridership estimates for new proposed rail services
- As an "order-of-magnitude model," the total ridership forecast provides a rough estimate of ridership
- The model does not produce boarding or alighting data by station. The boardings per station include riders that may have previously boarded at the Lowell station or any other station, but now choose to board at a new station. The Central Transportation Planning Staff (CTPS) on-board survey completed in 2008-2009 indicates that for the existing Lowell line, Boston's North Station accounts for 85 percent of all inbound alightings. It is reasonable to expect local or regional passenger service on this line would have a similarly high percentage of inbound alightings at North Station.

7.1.2 Aggregate Rail Ridership Forecasting Model 2.0 Overview

The model, as described in the ARRF2 Model Application Guide, is as follows:

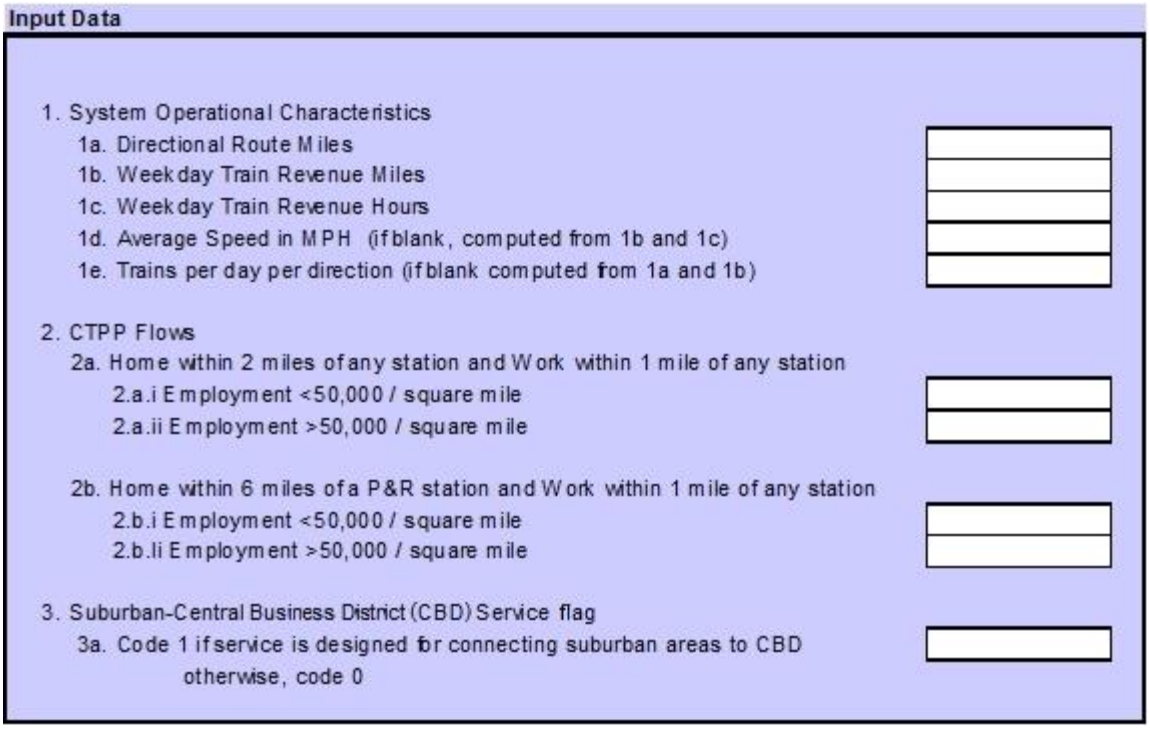
> *This model estimates total unlinked rail transit trips for light rail and commuter rail systems by applying a series of expected rail shares to the amount of total (all mode) travel to work occurring*

[22] For more detail on rail ridership forecasts, see Appendix 6 to the Capitol Corridor AA Final Report (Task 6 Evaluation Criteria and Methodology)

within the rail corridor as recorded in the Year 2000 Census Transportation Planning Package (CTPP). Ridership is adjusted up or down to account for the level-of-service (speed and frequency) of the modeled rail line as compared to the baseline values for the rail lines used to calibrate the model. This model is intended to develop order-of-magnitude estimates of ridership for new rail lines in metropolitan areas.

The model uses the CTPP worker flows, station locations, and service operational characteristics to estimate ridership. The service operational characteristics are based on the proposed service, the rail station locations with distance-buffers using Geographic Information System (GIS) software, and the CTPP data to estimate the worker flows within the service area. Figure 7.1 shows the input data setup required to run the ARRF2 model.

Figure 7.1: ARRF2 Inputs



7.1.3 Project Use of ARRF2

For the Capitol Corridor preliminary forecast, ARRF2 was applied to the existing MBTA Lowell Commuter Rail line to determine a baseline value. Each alternative was analyzed as in incremental addition to the service corridor.

7.1.4 ARRF2 Base Case Lowell Line Forecast

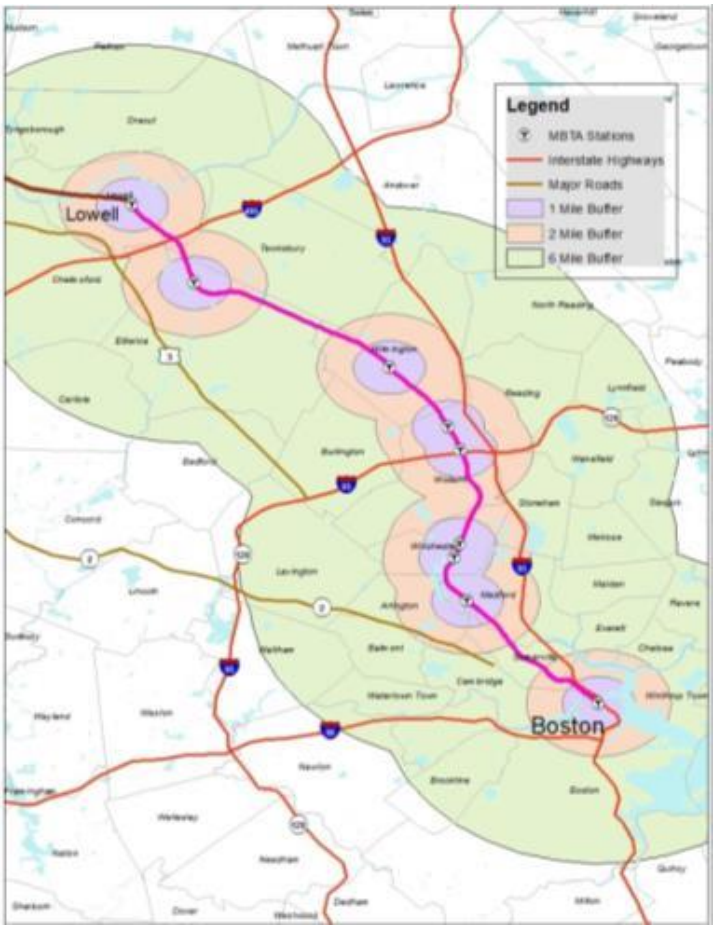
The ARRF2 model was used to produce daily ridership forecasts for the commuter and intercity rail service options. Prior to analyzing the alternatives, the existing MBTA Lowell commuter rail line was

tested using the ARRF2 model to establish a benchmark for the ARRF2 model to use as an adjustment to the alternative forecasts.

The ARRF2 model uses buffers around the rail stations to determine the catchment area for work flows. Figure 7.2 shows the one-, two-, and six-mile buffers around the existing MBTA Lowell commuter line. The ARRF2 model produced a forecast of ***9,096 riders*** using the Lowell line's operational characteristics and CTPP worker flows.

7.1.5 System Operational Characteristics

Figure 7.2: Existing Lowell Line Station Buffers



ARRF2 uses several system characteristics that describe the rail service's operational parameters as inputs to the forecasts. Specific characteristics used by the model include round trip route miles, average train speed, and the number of trains per day. The round trip route miles are used to provide the model with information regarding the extent of the system. The figures for average train speed and number of trains inform the model concerning the quality of service being provided. The weekday train revenue miles and weekday revenue hours are used to calculate the average train speed. The weekday revenue miles and the round trip route miles are used to calculate the number of trains per day.

7.1.6 CTPP Flows

CTPP data was used to approximate the market of trips that travel within the corridor. These worker flows were split into various submarkets that were used to estimate the magnitude of "walk-to" and "drive-to" markets for each train station. The "walk-to" flows are estimated using the number of households within a two-mile radius of any train station on the line. These flows are further segmented by the number of households that have travel flows to areas within a one-mile radius of any station, by employment densities less than 50,000 employees per square mile and by work flows to areas with more than 50,000 employees per square mile.

Park-and-ride flows are estimated using the number of households within a six-mile radius of any train station on the line. These flows are further segmented by the number of households that have workflows to areas within a one-mile radius of any station, by areas with employment densities less

than 50,000 employees per square mile, and by those with work flows to areas with greater than 50,000 employees per square mile.

7.1.7 ARRF2 Lowell Line Forecast: System Operational Characteristics

The Lowell station is 25.5 rail miles from North Station in Boston, which gives the base service a total of 51 direction route miles of service. Based on the current train schedules, the service offers 1,299 weekday train revenue miles and 38.52 weekday train revenue hours.

7.1.8 Base CTPP Travel Flows

Using the two-mile station buffering procedure for the existing Lowell line, the total number of households within two miles of a station that had employment within one mile of a station was 16,111 households (see Table 7.1). Of these households, 8,231 are employed in areas with less than 50,000 employees per square mile and 7,880 are in areas with more than 50,000 employees per square mile.

The six-mile buffer for park-and-ride trip estimation, results in 49,909 households within six miles of a particular station and employed within one mile of a different station. A total of 22,770 and 27,139 households are employed in areas with less than, and greater than, 50,000 employees per square mile, respectively.

Table 7.1: Lowell Line Base CTPP Flows

CTPP Flows	Base
Home within two miles of any station and Work within one mile of any station	
Employment <50,000/square mile	8,231
Employment >50,000/square mile	7,880
Home within six miles of a Park-and-Ride (P&R) station and Work within one mile of any station	
Employment <50,000/square mile	22,770
Employment >50,000/square mile	27,139

7.2 Preliminary Intercity Rail Forecasts

The operational characteristics of the proposed intercity regional services are based on the number of daily trains and the average speed. These values are shown in Table 7.2.

Table 7.2: Intercity Service Statistics

	Intercity 8	Intercity 12	Intercity 18
Route Miles (Round Trip)	146.8	146.8	146.8
Weekday Train Revenue Miles	586	880	1,319
Weekday Train Revenue Hours	12:40	19:00	28:30

The buffers used for the alternative analysis are presented in Figure 7.3. Depending on the stations included in each intercity and commuter rail alternative, some or all of these buffers were used.

7.2.1 New Hampshire CTPP Worker Flows

The worker flows can be broken down into three groupings for the alternatives, including the existing Lowell line worker flows plus each incremental extension: the Nashua flows, the Nashua/Manchester flows, and the Nashua/Manchester/Concord flows.

ARRF2 evaluated the incremental differences in service to analyze the alternatives. The CTPP flows shown in Table 7.3 are for the entire corridor and include those for the existing Lowell line. It shows that the incremental difference in flows for each of the alternatives is simply the difference between the alternative flow and the base flows for the MBTA Lowell line.

Figure 7.3: NHML Proposed Station Buffers

Table 7.3: Lowell Line Base and Intercity CTPP Flows

CTPP Flows	Base (A)	Intercity Rail Markets (Concord, Manchester, Nashua) (B)	Incremental Intercity Flows (B-A)
Home within two miles of any station and Work within one mile of any station			
Employment <50,000/square mile	8,231	11,046	2,815
Employment >50,000/square mile	7,880	8,147	267
Home within six miles of a P&R station and Work within one mile of any station			
Employment <50,000/square mile	22,770	30,951	8,181
Employment >50,000/square mile	27,139	27,818	679

7.2.2 Comparison of Observed and Forecasted Ridership

The MBTA Lowell line sees approximately 8,745 daily boardings, whereas the base forecast was for 9,096 boardings. Using this actual and alternative forecast ridership and a boarding factor of 1.9, a combined scaling and rider-to-board conversion factor was developed to adjust the alternative forecasts. The scaling factor corrects for error in the base condition (existing) forecast, and the boarding factor converts boardings to riders. Table 7.4 lists the unadjusted and adjusted forecast for each alternative.

Table 7.4: Adjusted and Unadjusted Alternative New Riders Forecasts

Alternative	Unadjusted Forecast	Adjusted Forecast
Base	9,096	8,745
Intercity 8	659	633
Intercity 12	769	740
Intercity 18	913	878

7.2.3 City Boarding Distribution

The gross forecasts of ridership were allocated to three origin regions as a first step toward deriving station-level forecasts. The CTPP flow data and service information for each city were combined to allocate boardings at the city level. Since these market shares were based on the magnitude of worker flows within the corridor, it is understandable that Nashua was shown to have the largest market share (see Table 7.5). This means that while Manchester is the larger city, more Nashua residents work in the Boston area than residents of Manchester. These market shares were then weighted by the number of trains that would stop in each city for the various alternatives.

Table 7.5: City Market/Level of Service Weighted Distribution Factors

	Market Distribution		
Alternative	Nashua	Manchester	Concord
Intercity 8	0.51	0.39	0.10
Intercity 12	0.51	0.39	0.10
Intercity 18	0.51	0.39	0.10

7.2.4 Station Boarding Distribution

The second step in deriving station-level forecasts was to distribute the city-level forecasts to the proposed stations. To allocate the boardings in cities with two or more stations, the Study team used the population within the six-mile catchment area and an accessibility factor. For the intercity services, the only necessary station allocation involved Bedford/Manchester Airport and the downtown Manchester Station, which were allocated at 53 percent to downtown Manchester and 47 percent for Bedford/Manchester Airport.

7.2.5 Preliminary Ridership and Boarding Estimates

Table 7.6 presents the preliminary total ridership and southbound boarding estimates for the three intercity rail service options as determined using the ARRF2 forecasting model.

Table 7.6: Preliminary Total Ridership and Southbound Boarding Forecasts

	Total Ridership	Southbound Boardings
Intercity 8	1,260	630
Intercity 12	1,480	740
Intercity 18	1,760	880

7.2.6 Station Southbound Boarding Distribution

Preliminary station-level southbound boarding and total ridership estimates are presented in Table 7.7.

Table 7.7: Rounded Total Ridership and Station-Level Boarding Estimates

Alternative	Total Ridership	Northbound Boardings	Southbound Passenger Boardings			
		Boston	Nashua	Bedford/MHT	Manchester	Concord
Intercity 8	1,260	600	320	120	130	60
Intercity 12	1,480	700	370	140	160	70
Intercity 18	1,760	840	440	160	190	90

7.2.7 Preliminary Estimates of Passenger Miles

Estimates of the passenger miles that would be expected from each service option were developed for the purposes of comparing alternatives on their mobility benefits and to facilitate derivation of revenue forecasts (see Table 7.8). Weekday passenger mile estimates were derived by multiplying the forecast southbound boardings at each station by the distance from each station to Boston North Station. This product was then doubled to reflect the mileage resulting from returning northbound trips.

Table 7.8: Forecast Southbound Boardings and Weekday Passenger Miles

Intercity Rail Station	Miles to Boston	Forecast Boardings			Weekday Passenger Miles		
		Intercity 8	Intercity 12	Intercity 18	Intercity 8	Intercity 12	Intercity 18
Concord	73.3	60	70	90	8,796	10,262	13,194
Manchester	55.5	130	160	190	14,482	17,824	21,166
Bedford/MHT	50.1	120	140	160	12,024	14,028	16,032
Nashua	39	320	370	440	24,960	28,860	34,320
Totals		**630**	**740**	**880**	**60,262**	**70,974**	**84,712**

7.2.8 Intercity 8 Forecasts

A separate more refined forecast for the selected Intercity 8 option was prepared in collaboration with Amtrak and its ridership forecasting consultant, which has been supporting Amtrak's Market Research and Analysis Department with ridership and ticket revenue forecasts for all of Amtrak's services across the U.S.[23] For Study purposes, Amtrak estimated ridership on the 73-mile, eight-train-per-day Concord

[23] For more detail on final forecasts for all final options, see Appendix 6 to the Capitol Corridor AA Final Report (Task 6 Evaluation Criteria and Methodology)

service by analogy to the nearby 114-mile, 10-train-per-day *Downeaster* service. Each station on the proposed Intercity 8 service was associated with a *Downeaster* "surrogate" station with similar travel time, station demographics, and train service characteristics. The model was then factored for differences between the surrogate *Downeaster* station and the proposed Capitol Corridor station. The Capitol Corridor stations and their *Downeaster* surrogate stations are shown in Table 7.9.

Table 7.9: Intercity 8 Station Associations (June 26, 2014)

NHML Existing and Proposed Stations			Surrogate *Downeaster* Stations		
Station Name	**Miles to Boston**	**Population**	**Station Name**	**Miles to Boston**	**Population**
Boston North Station	0.0	2,667,000	Boston North Station	0.0	2,667,000
Woburn, MA	12.6	1,087,000	Woburn, MA	12.6	1,087,000
Lowell, MA	25.2	746,000	Haverhill, MA	32.1	662,000
Nashua, NH	38.8	340,000	Exeter, NH	51	187,000
Bedford/MHT, NH	50.1	120,000	Durham, NH	62	83,000
Manchester, NH	55.5	266,000	Exeter, NH	51	187,000
Concord, NH	73.3	166,000	Dover, NH	68	162,000
Station Name	**Employment**	**Income**	**Station Name**	**Employment**	**Income**
Boston North Station	1,705,000	146,275,000	Boston North Station	1,705,000	146,275,000
Woburn, MA	574,000	60,660,000	Woburn, MA	574,000	60,660,000
Lowell, MA	370,000	40,388,000	Haverhill, MA	287,000	32,237,000
Nashua, NH	169,000	16,025,000	Exeter, NH	90,000	9,128,000
Bedford/MHT, NH	59,000	5,332,000	Durham, NH	36,000	3,297,000
Manchester, NH	134,000	12,112,000	Exeter, NH	90,000	9,128,000
Concord, NH	88,000	6,740,000	Dover, NH	64,000	5,921,000

Notes: 1) Based on county-level demographic data from Moody's Economy.com
2) Demographics calculated as follows: Determine the population, employment, and income within a 10, 15, 20, and 25-mile radius around the stations (as the crow flies), then multiply by factors of 1.4, 0.9, 0.5, and 0.2 respectively; the sum of these four numbers is the assumed station catchment area
3) Demographic differences between the primary and surrogate stations are adjusted for in the model

The model used Fiscal Year 2013 Amtrak *Downeaster* ridership/revenue data. In the Amtrak model for the *Downeaster*, Boston-Woburn (13 miles) had a higher observed yield than Boston-Haverhill (34 miles) in FY13. This Boston-Woburn/Boston-Lowell assumption has been maintained for the Capitol Corridor ridership estimates. Fares used in the ridership estimates are listed in Table 7.10.

Table 7.10: Intercity 8 Station Fares

Capitol Corridor Station	Surrogate Station	Weekday Fares	Weekend Fares
Boston North Station	Boston North Station	-	-
Woburn	Woburn	$12	$12
Lowell	Lowell	$6	$9
Nashua	Haverhill, MA	$7	$11
Bedford/MHT	Durham, NH	$10	$14
Manchester	Exeter, NH	$9	$14
Concord	Dover, NH	$13	$15

This intercity rail forecasting model, like most intercity rail forecasting models, predicts annual riders for station pairs along the line. Projected ridership by station pair is listed in Table 7.11. Total ridership along the line is projected to be 354,100 passengers per year.

Table 7.11: Annual Intercity 8 Ridership Estimates

	Concord	Manchester	Bedford/MHT	Nashua	Lowell
Concord					
Manchester	900				
Bedford/MHT	200	1,000			
Nashua	600	1,400	1,600		
Lowell	1,300	900	4,200	700	
Woburn	900	500	5,700	800	100
Boston	52,800	130,900	43,600	91,600	14,400

The station pair ridership data is condensed to the New Hampshire station-level annual ridership by summing the station trip origins and destinations at each station. The station-level ridership forecasts are converted to annual boardings by dividing the ridership by two, and annual boardings are converted to daily boardings by dividing by 365 days. These data are shown in Table 7.12.

Table 7.12: Intercity 8 Boarding Estimates

	Annual		Daily
Station	Ridership	Boardings	Boardings
Concord	56,700	28,350	78
Manchester	135,600	67,800	186
Bedford/MHT	56,300	28,150	77
Nashua	96,700	48,350	132
Total	345,300	172,650	473

7.3 Final Estimates of Passenger Miles

An estimate of the passenger miles that would be expected from Intercity 8 service option was developed to facilitate derivation of revenue forecasts and for the purposes of comparing with other non-intercity rail alternatives on their mobility impacts. Weekday passenger mile estimates were derived by multiplying the annual station pair forecasts by the station pair distance and dividing by 365 (see Table 7.13).

Table 7.13: Passenger Miles

Station	Passenger Miles		
	Annual	Daily	
Concord	2,014,305	5,519	24,762
Manchester	3,725,930	10,208	
Bedford/MHT	1,408,625	3,859	
Nashua	1,889,190	5,176	
Lowell	353,965	970	25,314
Woburn	242,810	665	
Boston	8,642,665	23,679	
Total	**18,277,490**	**50,075**	**50,075**

7.3.1 Forecast Reductions in Automobile VMT

The preferred Intercity 8 option would provide new service in the corridor, but unlike the existing commuter bus and proposed commuter rail services, it was not designed for the work-trip market in the corridor. It is assumed that the Intercity 8 riders will all be new transit riders that have diverted trips from automobiles. To convert passenger miles to vehicle miles, an average vehicle occupancy of 1.67 [24] persons per vehicle was used. The VMT reduction shown in Table 7.14 from the Intercity 8 service is not concentrated in the morning and afternoon peak periods as it is with the commuter bus and commuter rail options.

Table 7.14: Intercity 8 Change in VMT

Station	VMT Reduction	
Concord	3,305	14,827
Manchester	6,113	
Bedford/MHT	2,311	
Nashua	3,099	
Lowell	581	15,158
Woburn	398	
Boston	14,179	
Total	**29,985**	**29,98**

[24] 2009 National Household Survey Data, http://nhts.ornl.gov/tables09/fatcat/2009/avo_TRPTRANS_WHYTRP1S.html

8 Preferred Intercity Rail Service Design and Operations

This section describes the service design and provides an operations overview for the preferred Intercity 8 service option. Intercity 8 was selected from the three intercity rail service options because of its low net operating costs and reasonable level-of-mobility benefit. The number of additional riders attracted by more the frequent service that would be offered by Intercity 12 and 18 did not keep pace with the forecasted cost of the additional service. In preliminary estimates, Intercity 8 was projected to carry 946 daily passengers at a net operating cost of $3.6 million. By comparison, Intercity 12 and 18 would carry 1,104 and 1,308 daily passengers, respectively, at net operating costs of $6.9 and $11.8, respectively.

8.1 Design Objectives

In designing the Intercity 8 option, the Study team worked to maximize the service frequency that could be effectively offered with a single set of equipment and limited crews serving the five major population centers along the corridor: Concord, Manchester, and Nashua in New Hampshire and Lowell and Boston in Massachusetts. The design also would provide service to the suburban Massachusetts intermodal hub in Woburn served by intercity passenger rail service between Portland, Maine and Boston (Amtrak *Downeaster*). The operating characteristics of the successful *Downeaster* service were influential to the Intercity 8 design. Both services (the *Downeaster* and potential Intercity 8) would offer arrivals and departures at North Station at similar times of day.

8.2 Design Constraints, Assumptions, and Paradigms

In designing the service, the Study team was guided by the following constraints, assumptions, and paradigms:

- The new service must overlay onto the existing schedule and mix of passenger trains currently using North Station, including all of MBTA's north side commuter rail service and Amtrak's *Downeaster* service. The design needed to be particularly cognizant of the 68 weekday MBTA and Amtrak passenger trains that use portions of the route between Lowell and Boston.
- To gain acceptance from the host railway, the service needs to be completely transparent to existing MBTA customers.
- To minimize required capital investment and maximize benefits from a limited capital budget, it was assumed there would be no upgrades to infrastructure south of Lowell where successful passenger services are already offered. Instead, investments would be focused along the portions of the route that are currently "freight-only."
- Also to minimize required capital investment, the service was designed to respect limited capacity at North Station. MBTA has allowed that one new peak period arrival/departure by an intercity train could be accommodated at North Station once the currently inoperable Tracks 11 and 12 are put into service.

- Also to minimize capital expenditure, any track improvements would need to stay within the existing rail right-of-way. The line follows the banks of the Merrimack River for most of its route between Lowell and Concord. Since the frequency of curves and degree of curvature associated with the line is quite high due to its riverine routing, this constraint had a significant impact on maximum allowable speeds north of Lowell.
- To provide for harmonious operations with PAR (the freight carrier and owner of the route in New Hampshire), the Study team focused on providing industrial siding tracks at key locations along the line to avoid conflicts between intercity passenger trains and local freight train pick-ups and deliveries at customer locations.

8.2.1 Intercity 8 Design Overview

Meetings with Amtrak, MassDOT, and MBTA in the Spring of 2013 indicated a willingness to work with NHDOT on the provision of passenger service along the NHML from New Hampshire to North Station. This cooperation would take the form of Amtrak operation of intercity trains into New Hampshire or MBTA operation of commuter trains along the same route. The MBTA felt that two new station tracks would be opened at North Station with the imminent relocation of the Spaulding Hospital immediately to the west, providing capacity for one additional peak Amtrak train in each direction. MBTA would also be willing to extend its service into New Hampshire provided that the service extension was essentially transparent to existing MBTA passengers using the services offered between Lowell and Boston.

The Study team devised a hierarchy of three conceptual services that could be operated as an independent Amtrak service 73 miles northward from North Station to Concord, New Hampshire. The options were based on NHML historic and current physical attributes, the schedule of passenger services on the line, and general service parameters for Amtrak services in corridors of less than 150 miles. Each service would have the following characteristics:

- Operate independently of the MBTA and Amtrak *Downeaster* passenger services already serving the southernmost 25 miles of the route
- Require no upgrades to infrastructure south of Lowell
- Require upgrades to rail infrastructure north of Lowell:
    - Upgrades to 48 miles of existing track to FRA Class 4 providing for maximum passenger train speeds of at least 70 mph[25]
    - Installation of two or more industrial sidings between Nashua and Concord allowing passenger trains to pass or meet freight trains serving these segments

[25] Initially 70 mph was initially selected as no historic records showed higher speeds along the route since its opening in the 1800s; further later analysis indicated that 75 mph maximum allowable speeds could be supported for a relatively short segment between Nashua and Manchester

- Installation of a passing siding on the PAR freight main line west of North Chelmsford to reduce the need for trains to stand east of North Chelmsford on the route between Lowell and Nashua; MassDOT and MBTA have since committed to providing this passing siding independent of this planning initiative to solve capacity problems on the adjacent Fitchburg route also shared by MBTA and PAR trains
- Installation of NORAC Rule 261 signals between Manchester and Concord (approximately 18 miles)
- Installation of PTC protection

The proposed services would call at six passenger stations north of Boston (see Table 8.1).

Table 8.1: Proposed Stations with Distance and Travel Time to Boston

Station	Miles to Boston	Approximate Travel Time to Boston
Concord	73.3	1:29
Manchester	55.5	1:09
Bedford/MHT	50.1	1:01
Nashua	38.8	0:48
Lowell	25.5	0:32
Woburn	12.6	0:16

The projected travel times compare favorably with historic minimum travel times between Concord and Boston (see Table 8.2). The presumed maximum allowable speeds between Lowell and Concord and the proposed NHML maximum allowable speeds are shown Figure 8.1.

Table 8.2: Historic Minimum Concord-Boston Travel Times

	1910	1926	1945	1954

Source: Jacobs' analysis of archived public timetables

Figure 8.1: Proposed NHML Maximum Allowable Speeds

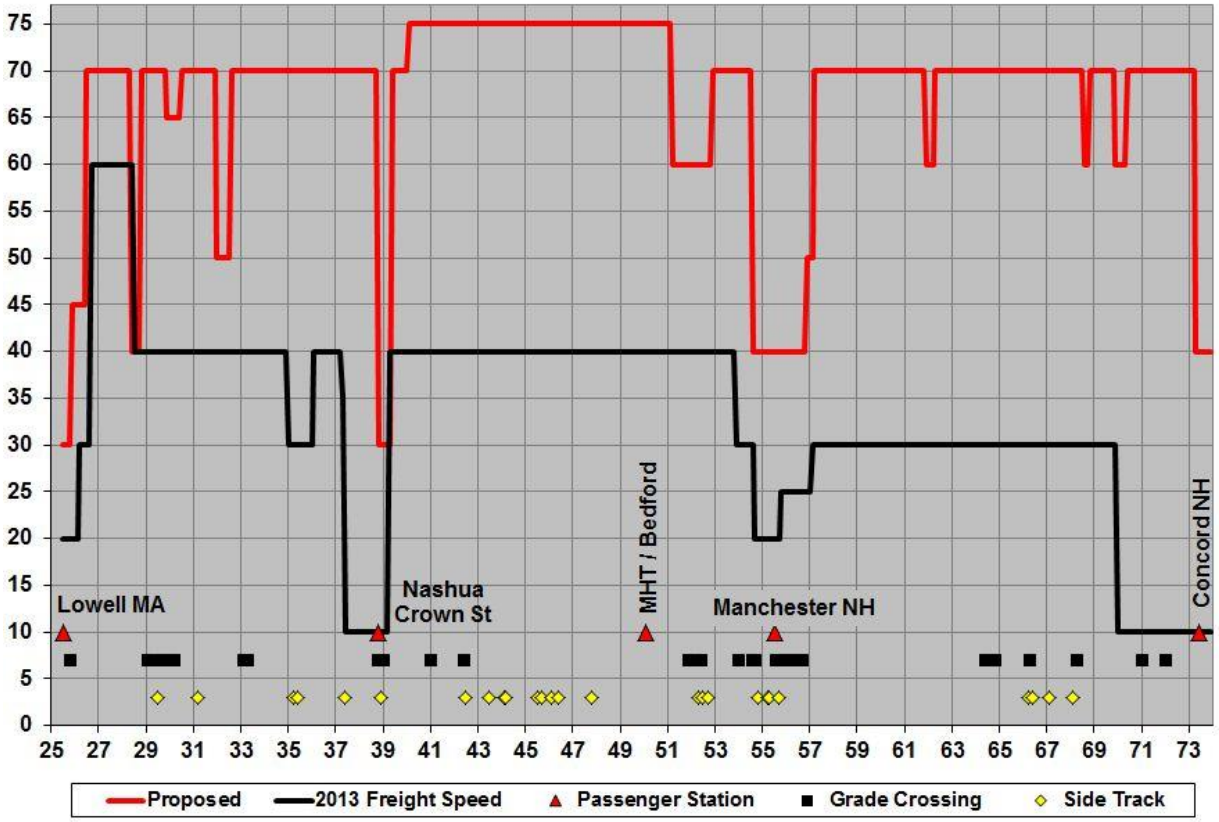

Table 8.3 summarizes the three conceptual Amtrak services that were considered for restoration of passenger service on the line. The Intercity 12 and Intercity 18 options were ultimately screened out from further consideration.

Table 8.3: Operating Characteristics of Proposed Intercity Rail Service Options

Options	Weekday Revenue Trains			Route Miles	Stations	Weekday Train Miles
	Nashua	Manchester	Concord			
Intercity 8	8	8	8	73	6	586
Intercity 12	12	12	12	73	6	880
Intercity 18	18	18	18	73	6	1,319

Each intercity rail and commuter rail service was designed using custom train scheduling and stringline diagraming tools used for many rail scheduling and planning assignments at MBTA and other passenger railroads. Given the relatively low density of freight traffic on the NHML, it was decided in consultation with the FRA that full Rail Traffic Controller (RTC) simulation models of the route would not be necessary for this particular Study.

8.2.2 Intercity 8 Rail Service

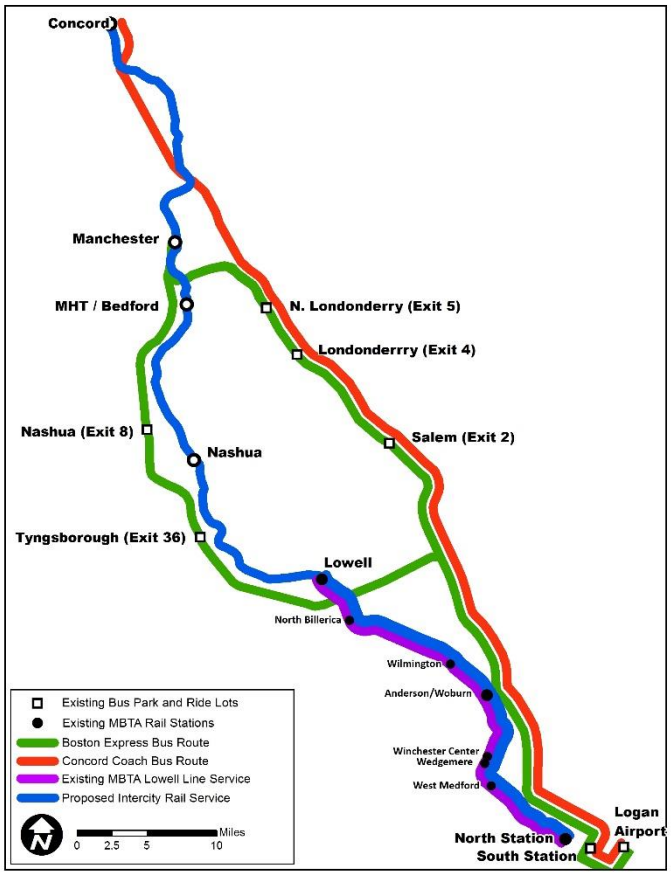
- Four daily intercity passenger rail round trips between Concord, New Hampshire and Boston, Massachusetts making intermediate stops at Manchester, Bedford/Manchester Airport, Nashua Crown Street, Lowell and Woburn, Massachusetts
- Base BX bus service is retained

The eight-train-per-day Intercity 8 rail option would provide four daily round trips over the 73-mile route, stopping at five intermediate stations (see Figure 8.2). The end-to-end trip time would be approximately 96 minutes and the service would operate 586 daily train miles.

A proposed timetable for the service is shown in Table 8.4. A full NHML schedule is found in Figure A.1 in Appendix A and a stringline time-distance diagram showing the proposed service integrated with the existing MBTA service on the line is found in Figure 8.3.

Presuming an average cost of $36 per train mile based on recent experience of the nearby Amtrak *Downeaster* service, Intercity 8 would cost approximately $7.7 million per year to operate.

Figure 8.2: Intercity 8 Rail Service



The service could be extended with possible connections to private bus services for North Country destinations. No changes are proposed to express bus service for commuting to Boston via I-93 or Route 3. Local bus service to the intercity rail stations could be offered but would not be integral to the service design. A BX/Concord Coach/intercity rail fare integration scheme similar to that employed by the *Downeaster* at Portland, Maine could be employed at the Concord and Manchester stations that would be shared by both intercity rail and coach bus services.

Table 8.4: Proposed Intercity 8 Timetable

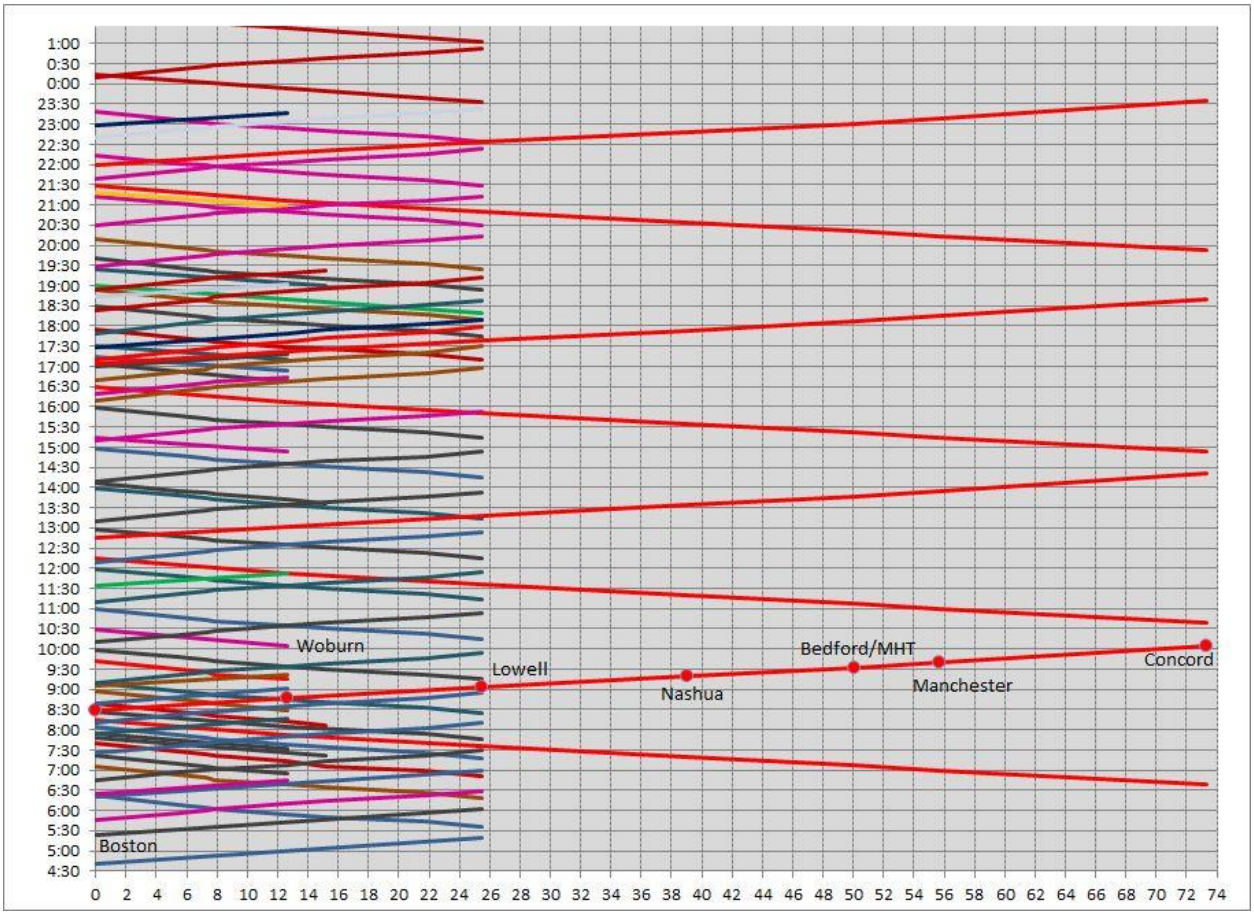
380	382	384	386		Station	MP		381	383	385	387
6:39	10:39	14:54	19:54	Read Down	Concord, NH	73.3	Read Up	9:59	14:14	18:49	23:39
6:58	10:58	15:13	20:13		Manchester, NH	55.5		9:38	13:53	18:28	23:08
7:07	11:07	15:22	20:22		Bedford/MHT	50.1		9:30	13:45	18:20	23:00
7:20	11:20	15:35	20:35		Nashua	38.8		9:17	13:32	18:07	22:47
7:36	11:36	15:51	20:51		Lowell	25.5		9:02	13:17	17:52	22:32
7:52	11:52	16:07	21:07		Anderson/Woburn	12.6		8:46	13:01	17:36	22:16
8:15	12:15	16:30	21:30		North Station	0.0		8:30	12:45	17:20	22:00

It is presumed that service would be offered with a single push-pull locomotive hauled train set with four coaches. The rolling stock would be similar in configuration and performance to the equipment used for the *Downeaster* and MBTA commuter rail service. The train set would be stored and serviced overnight at the Concord Station where a plug-in and basic cleaning and servicing facilities would be provided. It is assumed that the intercity service would be operated from the same pool of equipment used to provide *Downeaster* service with an extra locomotive and control coach added to that pool to offset the additional burden this service would create. Amtrak would provide heavy maintenance at its facilities in Boston's Southampton Street Yard or further south on the Northeast Corridor as is the practice with the *Downeaster* equipment.

Two crews would be required to provide service each day. One crew would handle Trains 380 to 383; while the other crew would handle Trains 384 to 387. A full roster of three crews plus a spare would be necessary to handle routine service requirements. The minimum required crew would be an engineer and conductor, although it is likely that Amtrak would operate the service with a third crew member to assist with operation of doors and management of passengers.

For Study purposes, it was presumed that the service would be operated by Amtrak. Certain economies in crewing, equipment maintenance, and administrative overhead might be available if the service were operated by MBTA and its passenger rail contractor in a manner similar to the operation of their new 78-mile Cape Flyer service. The Cape Flyer started in the summer of 2013 as a seasonal weekend-only experiment. After two seasons of operation, it appears that it may become permanent and a model for the operation of other short distance intercity rail services into Boston.

Figure 8.3: Intercity 8 Stringline/Time-Distance Diagram



9 Preferred Intercity Rail Station and Layover Facilities

This section describes the design requirements and evaluation criteria used to identify and assess potential sites for passenger rail stations and layover facilities proposed to support the Intercity 8 option It then describes the recommended sites, evaluates their performance, and provides preliminary designs, where appropriate. A total of eight intercity passenger rail stations and three layover site options were identified through a combination of stakeholder meetings and public outreach, review of existing and historical conditions, previous studies, and field inspections. Following assessment, four stations and one layover facility were recommended for the Intercity 8 service.

9.1 Design Requirements

Each of the rail stations would require American Disabilities Act (ADA) compliant platforms for passengers to board and alight the trains, provide a canopy for shelter, have provisions for buses and automobiles to pick-up and drop-off passengers, and provide direct access to and from major highways and nearby land uses. All but one station would require parking designated for rail passengers. Sites located in downtown Manchester are too constrained to provide dedicated commuter parking, but ample public parking capacity is located within short walking distance of the identified sites.

Where possible, the Study team designed platforms that were “high-level” for their full length. High-level platforms ease boarding for all passengers by eliminating the need for stairways to climb into and out of the passenger coaches. High-level platforms may conflict with freight train movements; therefore, a short 85-foot-long section of high-level platform, commonly referred to as a “mini-high,” might be substituted for a full-length, high platform at some stations. Platform specifications are listed below:

- Low-level platforms must be eight inches above the top of rail
- High-level platforms must be 48 inches above the top of rail
- The preferred side platform width is 12 feet; 10 feet is acceptable and eight feet is the absolute minimum width
- Long side-platforms may taper to a minimum width of eight feet at the ends
- The preferred center-island platform width is 22 feet for a minimum of half the platform length
- Long center-island platforms may taper to a minimum width of 12 feet at the ends
- Outbound platforms should be 765 feet long (shorter platform lengths could be accommodated for the initial service, but longer platforms would provide more room for growth and flexibility in service design and operations)
- Inbound platforms of a minimum 710 feet would be permissible

Table 9.1 identifies the eight potential Intercity 8 station site locations and preliminary site requirements.

Table 9.1: Potential Intercity 8 Station Sites

Station	Requirements	Potential Sites
Nashua	▪ Downtown station to anchor future Nashua TOD ▪ P&R availability ▪ Integrate with local NTS bus service	▪ Crown Street ▪ Beazer East
Bedford/MHT	▪ P&R station for commuter rail and intercity rail options ▪ Shuttle Bus to Manchester Airport ▪ Direct Access to Route 3 and I-293	▪ NHDOT parcel below the Ray Wieczorek Drive/Pearl Harbor Memorial Bridge
Manchester	▪ Downtown anchor to support existing development and Manchester TOD ▪ Integrate with local MTA bus service and downtown intercity bus terminal	▪ Queen City Avenue ▪ Granite Street ▪ Spring Street/Bridge Street
Concord	▪ Downtown station to anchor Concord TOD ▪ Integrate with existing intercity bus terminal and local CATs bus service ▪ P&R availability	▪ Depot Street ▪ Stickney Avenue

Table 9.2 lists the number of station tracks required for Intercity 8. This was determined by evaluating the need for trains to turn or meet in stations, as indicated by the preliminary service schedules.

Table 9.2: Number of Required Intercity 8 Station Tracks

Station	Tracks
Nashua	1
Bedford/MHT	1
Manchester	1
Concord	1

The number of parking spaces proposed for each station was based on two factors: 1) forecast ridership and 2) functional station type (see Table 9.3). Downtown stations would provide parking only where available at the rate of one parking space for every two forecast riders. The regional P&R station at Bedford/Manchester Airport would provide one space for each forecast rider. The Nashua Crown Street station site is currently owned by the City of Nashua and has been proposed to accommodate up to 255 parking spaces. Only accessible parking spaces are proposed for downtown Manchester, since there are many pay-for-parking lots within close proximity of each proposed station site. Finally, there is an existing, heavily-utilized P&R lot at Stickney Avenue in Concord. Due to the nature of intercity travel, at least 100 additional spaces are proposed at this location even though this would exceed the one-space-per-forecasted-rider standard.

Table 9.3: Intercity 8 Preliminary Ridership Forecasts and Parking Space Requirements

	Total	Nashua	Bedford/MHT	Manchester	Concord
Ridership Forecasts	730	200	210	240	80
Parking Space Requirements	545	255	210	0-	100

9.1.1 Site Evaluation Criteria

The following list of evaluation criteria was developed to guide the station site selection process. The evaluation criteria measures were given a rating of one for poorly performing sites to five for highly performing sites. Environmental criteria was designated as Yes or No, while ownership criteria was designated G for government-owned or P for privately-owned.

1. Market
    - Does the site adequately serve the travel market of Boston-bound travel for residents of Nashua, Manchester, Concord, and surrounding towns?
2. Access
    - Is the site adequately served by major roads with connections to the regional highway network?
    - Is there existing parking available at the site?
3. Track Operational Characteristics
    - Is the track straight and free of existing sidings?
    - Are there any grade crossings adjacent to the site?
    - What are train deadhead cost savings and travel time efficiencies?
    - Requirement for new traffic/train signals?
    - Are bridge structures required for roadway access or yard leads?
    - Are freight rail movements/clearances maintained?
4. Parcel Size/Configuration/Ownership
    - Is there adequate land available for station platforms and facilities?
    - Is there sufficient land for parking lots sized to meet ridership forecasts?
    - What is the assessed value per acre?
    - Would displacement of residents/businesses be required?
5. Land Use
    - What are the predominant surrounding land uses?
    - What are municipal and community aspirations/priorities?
    - Consideration of environmental justice, including accessibility by minority populations and low-income households
6. Sensitive Receptors
    - Are there any residential buildings or educational, medical, or religious facilities near the site that would have a heightened sensitivity to noise or vibration impacts?

7. Environmental

    - Is the site adjacent to a river or within a flood zone?
    - Is the site in or adjacent to jurisdictional wetlands?
    - Does the site have a history of contamination?
    - Has the site been designated as a threatened or endangered species habitat?
    - Does the site have nearby sensitive receptors for noise/air quality impacts?

8. Ownership

    - Is the property owned by state or local government or is it privately held?
    - Is the property for sale or held by single or multiple owners?

9.1.2 Preliminary Station Sites

Multiple locations were identified for each of the five proposed stations based on field inspections, interviews with local officials, and a review of previous studies. Each of the evaluated sites and their MP distance from Boston are listed in Table 9.4 and discussed in detail below. Several sites were eliminated during the preliminary assessment, while eight locations were advanced for further evaluation.

Table 9.4: Intercity 8 Preliminary Station Sites

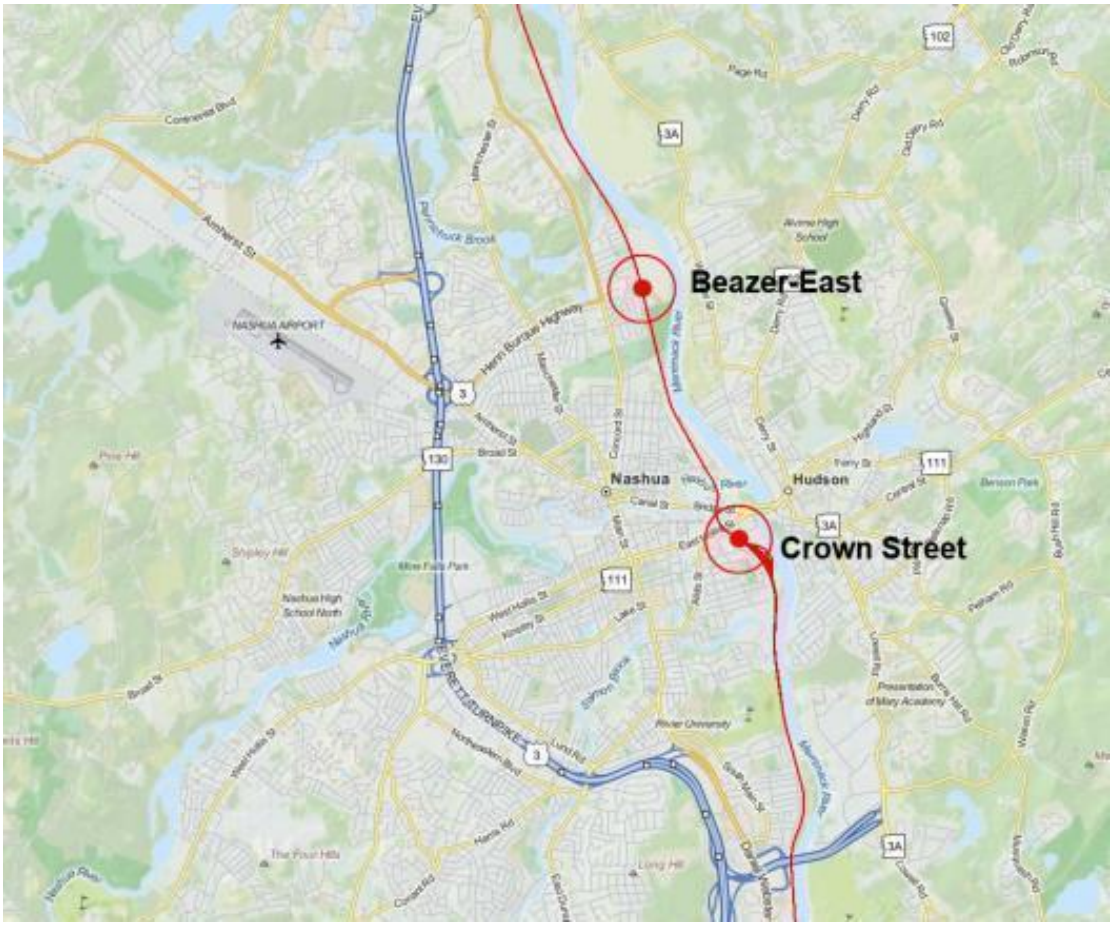
Station	Sites Evaluated	MP
Nashua	25 Crown Street	38.8
	Beazer East	41.0
Bedford/MHT	NHDOT parcel below Ray Wieczorek Drive	50.1
Manchester	Queen City Avenue/Jac-Pac	54.9
	Granite Street	55.5
	Spring Street/Bridge Street	56.4
Concord	Depot Street	72.6
	Stickney Avenue	73.3

Once the station sites were identified, schematic designs were overlaid on annotated aerial imagery prepared by Jacobs Engineering in September 2013. These schematic designs included tracks, switches, platforms, roadways, pathways, parking, circulation, buildings, and other related features. Parcel mapping information provided by municipalities and NHDOT was also incorporated as part of the schematic designs. It will be necessary for the schematic designs to be reviewed by Amtrak, MBTA, PAR, NHDOT, and other stakeholders prior to being finalized. The following sections describe and document each station site with findings from the initial site review. Parcel mapping, site photos, previous station site plans, preliminary schematics, and the proposed conceptual station plan are presented for preliminary environmental and financial review.

9.2 Nashua Station Options

Figure 9.1 illustrates the location of the two potential station locations that could be developed as a Nashua Station: Crown Street and the Beazer-East site.

Figure 9.1: Potential Nashua Station Locations



9.2.1 Nashua – Crown Street

This city-owned and locally preferred site for a downtown Nashua station is located south of Crown Street site and north and west of the PAR rail yard. It is the approximate location of Nashua's historic main line train station. Another station was located on the Hillsboro Branch at Railroad Square on Main Street.

Potential station locations were also evaluated at Bridge Street and East Hollis Street with regard to how a full-length (765-foot) passenger rail station platform could be configured on the site. The Bridge Street site was eliminated because only 520 feet would be available for a platform between the Nashua River railroad bridge on the north and the Bridge Street crossing on the south. The East Hollis Street site located between Bridge Street and East Hollis Street was also eliminated as the platform length would be limited to approximately 400 feet. Site features and challenges follow; see Figures 9.2 and 9.3 for photos and a parcel map, respectively, and Table 9.5 for summary evaluation ratings.

- The station platform would be located adjacent to the Triangle Pacific building, which could potentially be redeveloped
- It is the only viable site near downtown that can accommodate platform requirements
- City plans call for 255 parking spaces and reuse of existing industrial buildings
- Additional parking supply would be constrained by the size of the parcel

Figure 9.2: Nashua – Crown Street Site Photography

Facing southeast towards the PAR Rail Yard

Facing south towards the vegetated area west of the PAR Rail Yard where the proposed platforms would be located

Facing northwest as the NHML continues north, the Hillsboro Branch turns off towards the west

Facing west towards downtown Nashua

Figure 9.3: Nashua – Crown Street Parcel Map

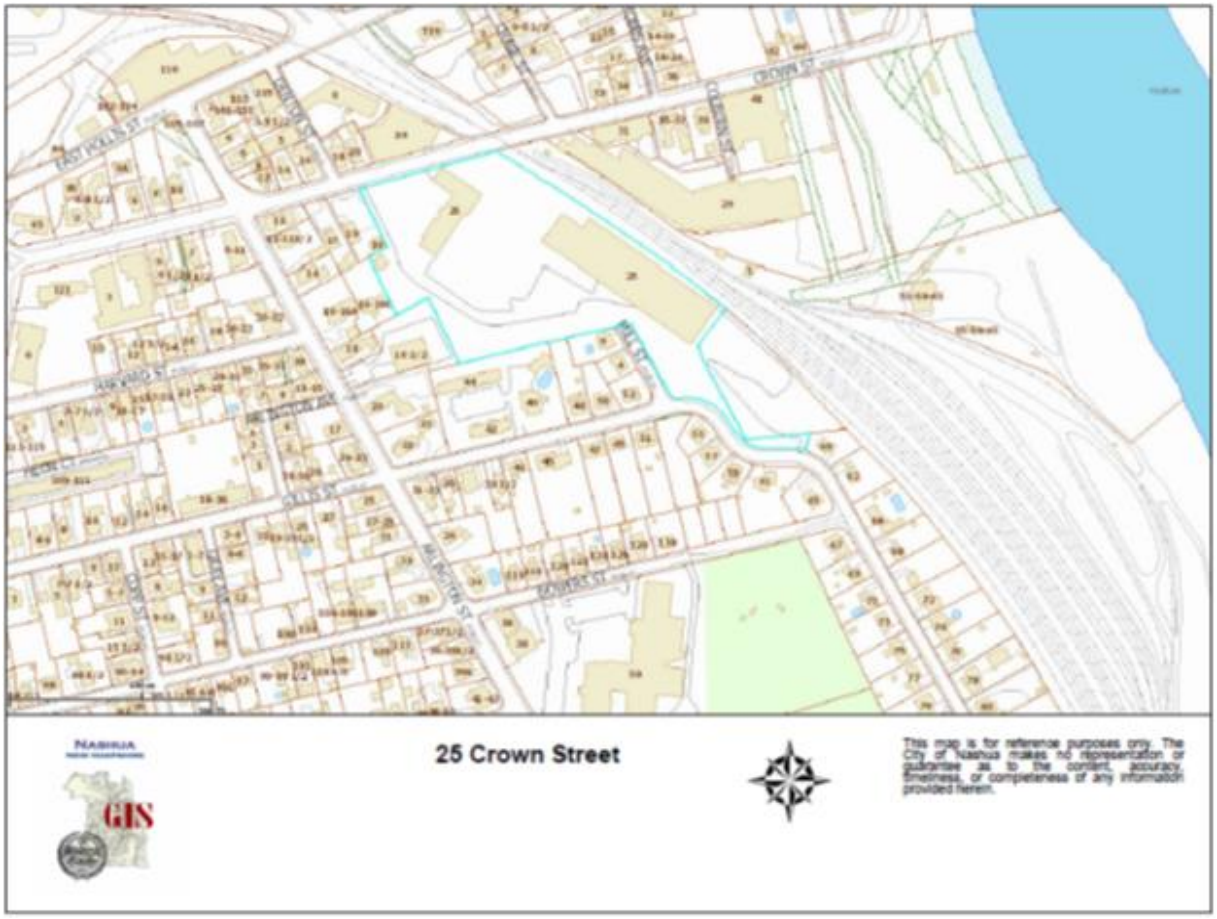


Table 9.5: Nashua – Crown Street Station Area Evaluation

Category	Rating	Notes
Market	4	Close (0.8 miles) to Main Street in downtown Nashua
Access	4	Multiple local road access points
Track	5	Only viable stretch of track in the downtown area
Land use	4	Future P&R site for the city, mixed industrial/residential
Parcel	5	Seven acre site owned by the city, designated for transit
Environmental	Y	Potential soil remediation, unknown; most likely urban fill. Possible complications from site demolition
Owner	G	Government-owned (City of Nashua)
Noise	Y	Mixed residential neighborhoods near site
Miscellaneous	Y	City would like to utilize this site as a park-and-ride location

Assessment: Advanced

This site is recommended as a downtown station for the City of Nashua. Local officials have been contemplating a station at Crown Street for several years with well-developed plans shown in Figure 9.4. The city and state recently cooperated to acquire the site with the intention of developing a P&R lot independent of the proposed rail service, as shown in Figures 9.5 and 9.6; a preliminary station design is shown in Figure 9.7.

Since this location would rely on pedestrian and bicycle accessibility, a new sidewalk would be necessary on the south side of Crown Street and east of Arlington Street to ensure safe site access. A pedestrian/bicycle connection off Harvard Street would provide improved accessibility from the surrounding neighborhoods.

Figure 9.4: City of Nashua Excerpt from East Hollis Street Master Plan

Figure 9.5: City of Nashua P&R Site Plan

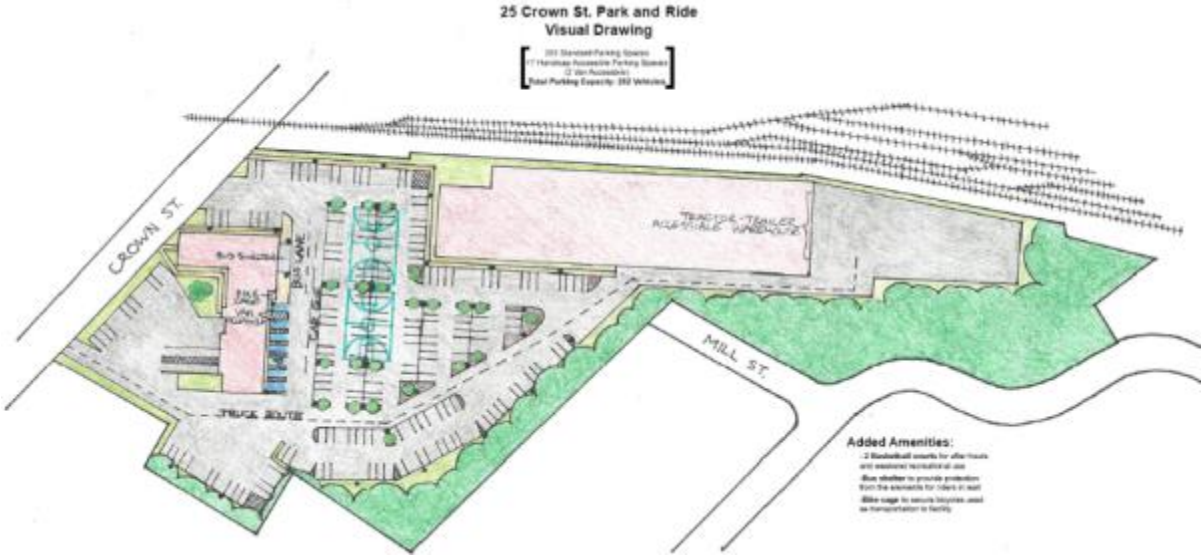

Figure 9.6: City of Nashua P&R Site Plan

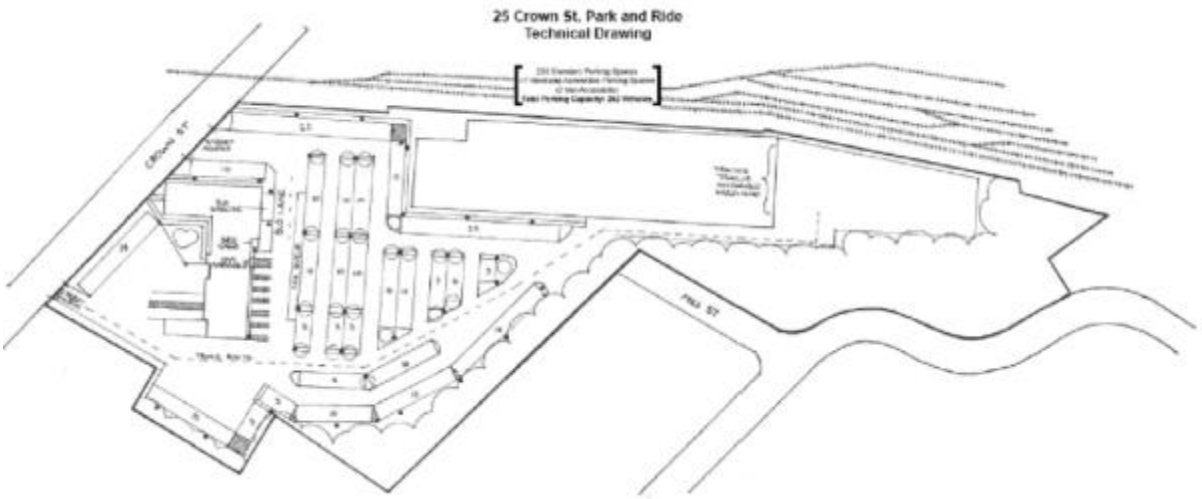

Figure 9.7: North Nashua – Crown Street Station Preliminary Station Design

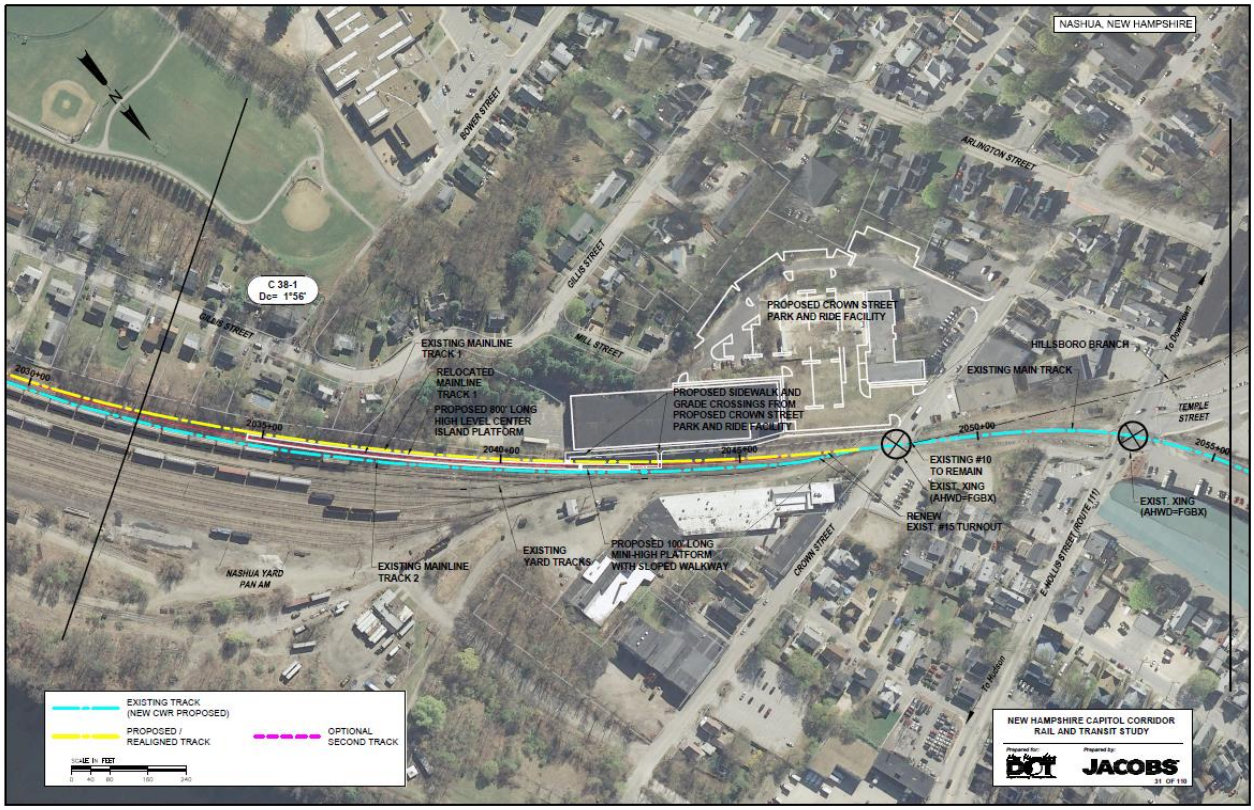

9.2.2 North Nashua – Beazer-East

The Nashua Beazer-East site is located in the southwest corner of a large industrial parcel owned by Beazer-East, Inc. The site was formerly owned by Koppers Company, a manufacturer of railroad ties. Their manufacturing operations included treating ties with creosote. The site was found to be contaminated with creosote and is currently in the process of being cleaned up. It is contemplated that the site will be developed once the remediation effort is completed. Land is principally residential immediately west of the site. Greeley Park, located to the south is owned by the City of Nashua, and is primarily used as a site for launching boats on the Merrimack River. Hills Ferry Road is currently the only access roadway across the railroad tracks into the site. The existing 36.5 kw power line right-of-way was proposed to allow the extension of Henry Burke Highway into the site with an overpass over the tracks, although this option was eliminated from further consideration in 2011. Two small industrial buildings are the only buildings currently on the parcel. The Brownfields site is north of downtown Nashua and does not relate well to current or future rail service or City of Nashua redevelopment plans. However, it does present a large undeveloped parcel along the railway. Site features and challenges include the following (see Figures 9.8 and 9.9 for photos and a parcel map, respectively, and Table 9.6 for summary evaluation ratings):

- 96 acres available, providing multiple options
- Access issues include the need to navigate through a residential neighborhood
- It may be possible to extend Hills Ferry Road into Greeley Park
- Further north, Pennichuk Street is another potential access path with local access options from Route 3 via Daniel Webster Highway and Concord Street
- Planned site development is mixed use retail and residential
- The site is free of wetlands, but adjacent to Merrimack River
- The site is contaminated with creosote and currently undergoing remediation

Figure 9.8: North Nashua – Beazer-East Station Site Photography

Monitoring wells

Remediation building

Hills Ferry Road at-grade crossing

Existing signal

Figure 9.9: North Nashua – Beazer-East Station Parcel Map

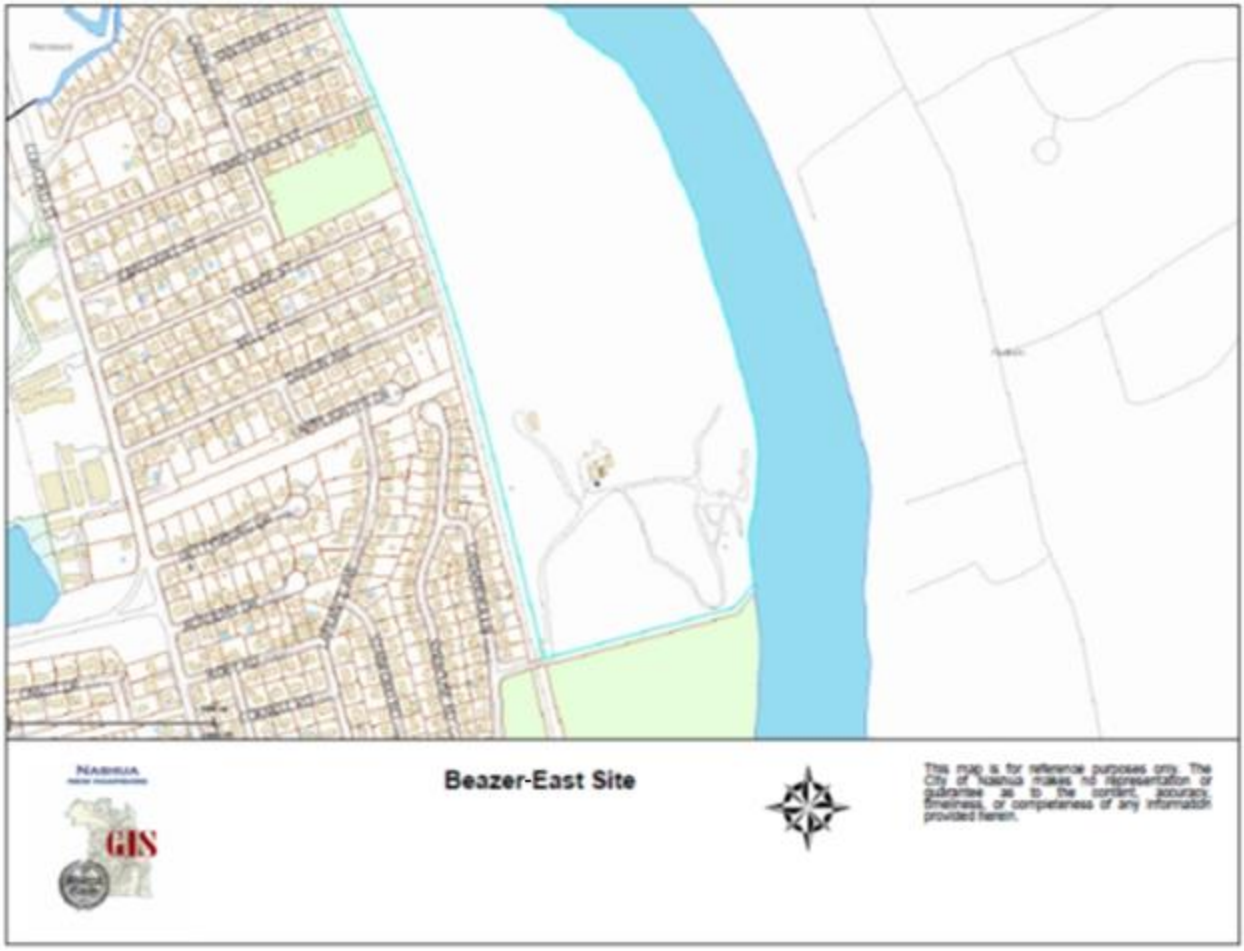

Table 9.6: North Nashua – Beazer-East Station Area Evaluation

Category	Rating	Notes
Market	2	Closer to Merrimack; City of Nashua residents would need to drive north to go south
Access	2	Indirect from Route 3, with access through a residential neighborhood
Track	5	Straight track, no issue
Land use	3	Vacant parcel, but adjacent to existing neighborhood
Parcel	5	Large vacant parcel, plenty of land
Environmental	Y	Site has existing soil contamination; would not interfere with proposed use
Owner	P	Privately-owned, available for development; a station here could help spur redevelopment
Noise	Y	Vacant lot with adjacent neighborhood
Miscellaneous	Y	Need to create new access

Assessment: Eliminated

This site was eliminated from further consideration due to the nature of its poor relation to potential rail service, site access constraints, and existing soil contamination.

9.2.3 Bedford/Manchester Airport

The proposed Manchester Airport station in Bedford would provide a location for air-rail passenger interchange and also serve as a regional P&R for northern Hillsborough and southern Merrimack counties. The site is located under the Ray Wieczorek Drive/Pearl Harbor Memorial Bridge that provides a direct connection between Route 3 and Manchester Airport. This site has also been proposed as a development node within the Town of Bedford. A proposed shuttle bus would meet all trains and provide connecting service along the 2.8 mile (six-minute) route between Manchester Airport's passenger terminal and the proposed station. Similar air-rail shuttle connections are used at airports in Baltimore, Boston, and Milwaukee. The station parking lot would be managed to avoid use by air passengers and keep spaces available for rail passengers. The Town of Bedford supports this station location and has developed plans for mixed use redevelopment in the vicinity of the station. Site features and challenges include the following (see Figures 9.10 and 9.11 for photos and a parcel map, respectively, and Table 9.7 for summary evaluation ratings):

- NHDOT owns the property on the south side of the bridge, some of which was set aside as mitigation as part of the bridge construction
- Property on the north side of bridge is privately held
- Sebbens Brook is a valuable environmental resource located on the south side of the bridge
- Access is difficult to the south of the bridge, although there may be the potential to develop site access through the existing parcel south of the brook
- A small brook and wetland areas also exist on the north side of the bridge
- A propane gas service yard on the north side of the bridge may need to be relocated
- A power line bisects the site north of the bridge

Figure 9.10: Bedford/Manchester Airport Station Site Photography

Railroad right-of-way facing south

Overhead power lines

Railroad right-of-way facing north

Wetlands adjacent to the proposed station

Figure 9.11: Bedford/Manchester Airport Station Parcel Map

Table 9.7: Bedford/Manchester Airport Station Area Evaluation

Category	Rating	Notes
Market	5	Only direct access point to the airport
Access	5	Direct access to the site from Ray Wieczorek Drive
Track	5	Straight unencumbered track
Parcel	4	Potential need to utilize multiple parcels
Land use	5	Mostly vacant, surrounding transportation uses
Sensitive Receptors	5	No sensitive receptors
Environmental	Y	Wetlands – values need to be assessed
Ownership	G/P	State owns some of the parcels, some are privately held

Assessment: Advanced

The proposed Manchester Airport station has been previously identified as a potential passenger rail station by state and local officials. Local plans, published in 2010, embrace the concept of a rail station along the river near the bridge linking Route 3 with the Manchester Airport (Figure 9.12). The station would be a focal point for regional travel and local development as well as for air-rail intermodal passenger transfers. An 800-foot long platform is proposed to be located on the west side of the tracks. The site also has ample room to accommodate the necessary parking without the need for additional land acquisition. Figure 9.13 shows the preliminary station design.

Figure 9.12: Town of Bedford Concept Plans for Manchester Airport Station Area (2010)

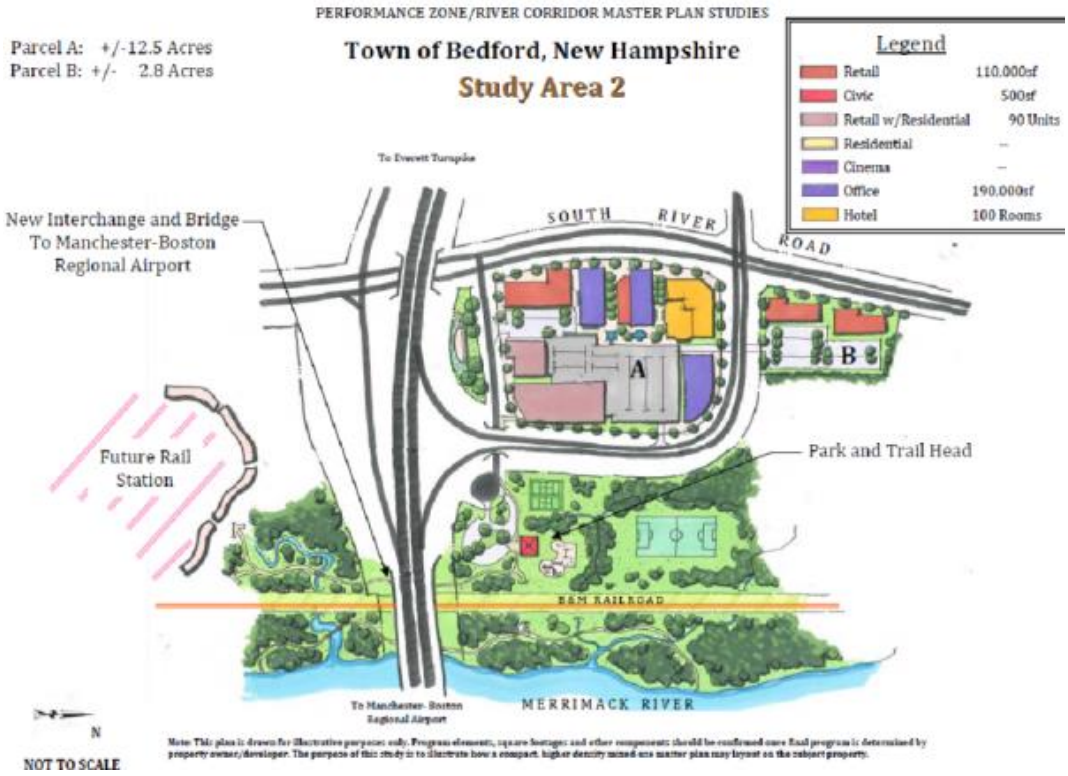

Figure 9.13: Bedford/Manchester Airport Preliminary Station Design

9.3 Manchester Station Options

Three station sites for downtown Manchester were identified and evaluated. Key roles to be fulfilled by the downtown Manchester station include serving as a downtown anchor to support existing development, support future Manchester TOD, integrate the passenger rail service with the local MTA bus hub, and provide multi-modal connections with Manchester's downtown intercity bus terminal.

9.3.1 Manchester: Queen City Avenue

The station proposed at the former "Jac-Pac" site is located under the Queen City Avenue Bridge where it crosses the railway. This location is situated approximately 7,500 feet (30-minute walk) from the downtown bus terminal and the southern end of Manchester's most intense urban development.

Figure 9.14: Historic Manchester Rail Station

Assessment: Eliminated

The Queen City Avenue site was suggested by local officials, but eliminated early in the site selection process due to its weak relationship to the existing downtown and distance from other transit services.

9.3.2 Manchester – Granite Street

Manchester's main passenger rail station stood for many decades on the south side of Granite Street before the building was demolished and the site redeveloped (Figure 9.14 on previous page). The site is proximate to the center of Manchester's densest urban development, across the street from the intercity bus terminal and a short walk to the MTA's downtown hub at Veteran's Park. Site features and challenges include the following (see Figures 9.15 and 9.16 for photos and a parcel map, respectively, and Table 9.8 for summary evaluation ratings):

- Close to downtown, ample private pay-parking available in nearby garages and surface lots
- Across Granite Street from the existing intercity bus terminal
- City of Manchester owns parcel 930-6, which is presently used for public parking
- 1,500 feet (five-minute walk) to MTA's local bus hub at Veteran's Park
- Direct access to I-293 (Exit 5)
- Existing development adjacent to the site and along the rail right-of-way

Figure 9.15: Manchester – Granite Street Site Photography

Facing south towards the location of proposed station platforms from the Granite Street at-grade crossing

Facing north towards the Millyard from the Granite Street at-grade crossing

Facing northeast towards the intercity bus terminal from the Granite Street at-grade crossing

Facing west towards I-293

Figure 9.16: Manchester – Granite Street Parcel Map

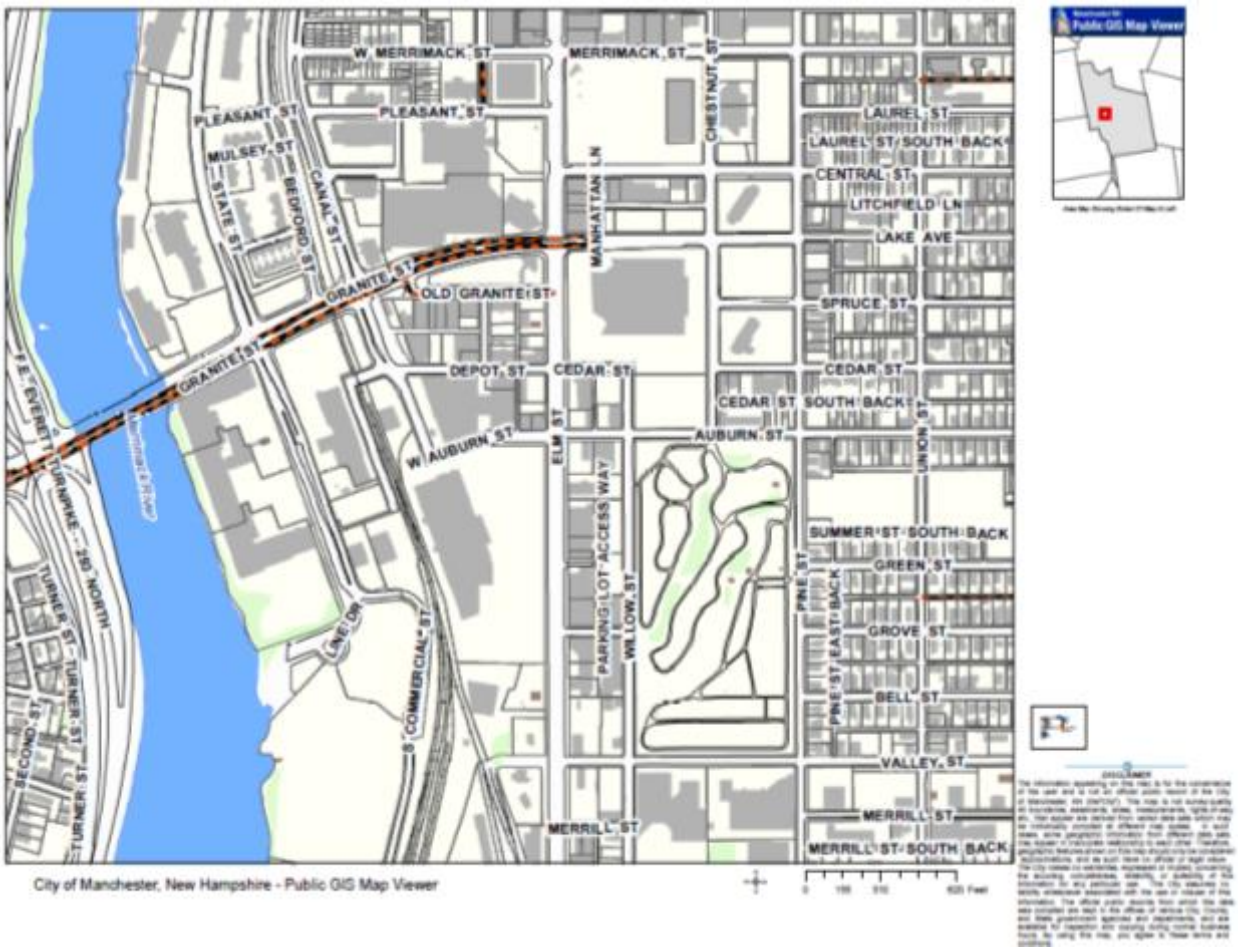

Table 9.8: Manchester – Granite Street Station Area Evaluation

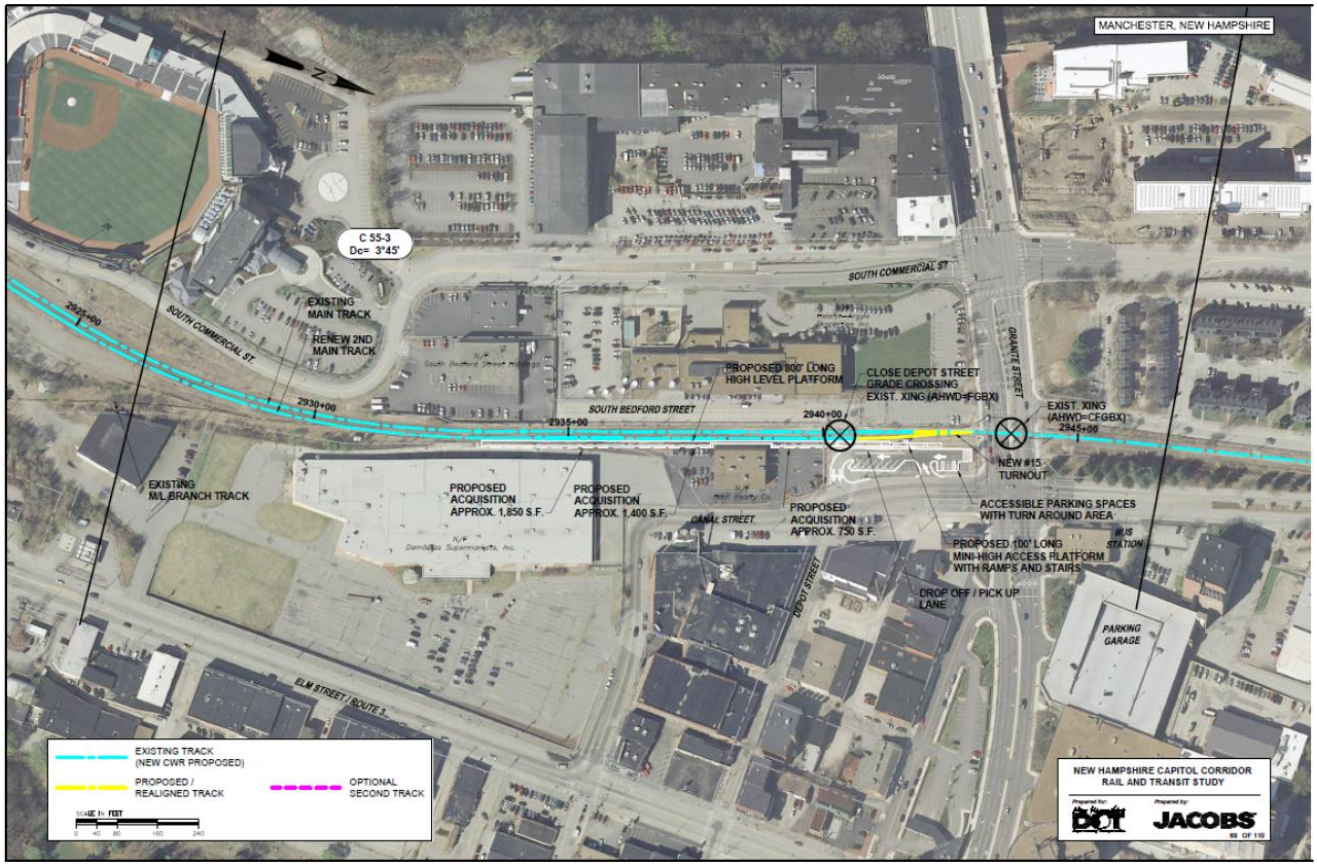
Category	Rating	Notes
Market	5	Located within downtown Manchester
Access	5	Direct access from I-293 with public parking lots and garages nearby
Track	5	Straight track, with no issues
Parcel	5	Tight space, may need surrounding properties for station facilities and parking would need to be located off-site
Land use	4	Existing commercial uses
Sensitive Receptors	4	Surrounding commercial buildings
Environmental	N	Nothing obvious
Ownership	P	Privately-owned railroad right-of-way

Assessment: Advanced

This site is recommended as the downtown station for the City of Manchester. The recommended station design would close the Depot Street crossing and develop the city-owned parcel on the corner of

Granite and Canal Streets that is presently used for public parking. A two-track station option has been developed with a high-level platform serving the east track. This would enable the efficient operation of a terminal station and allow for unimpeded freight traffic to and from the north. Figure 9.17 shows the preliminary station design.

Figure 9.17: Manchester – Granite Street Preliminary Station Design



9.3.3 Manchester – Spring Street/Bridge Street

The Manchester Spring Street/Bridge Street site is located on the north end of the Millyard District near the Spring Street grade crossing and under the Bridge Street overpass. The property is owned by the City of Manchester. There are a large number of jobs and existing surface and structured parking lots proximate to the site. Site features and challenges include the following (see Figures 9.18 and 9.19 for photos and a parcel map, respectively, and Table 9.9 for summary evaluation ratings):

- City of Manchester-owned parcel
- Indirect access to I-293 (Exit 6)
- Ample private parking available in adjacent surface and structured parking lots
- 2,500 feet (10-minute walk) from the intercity bus terminal at corner of Canal and Granite
- 2,900 feet (12-minute walk) to MTA the local bus hub at Veteran's Park

Figure 9.18: Manchester – Spring Street Site Photography

Facing north the location of proposed station platforms from the Spring Street at-grade crossing

Facing south from the Spring Street at-grade crossing

Facing southeast towards existing parking structure from the Spring Street at-grade crossing

Facing west towards the Millyard from the Spring Street at-grade crossing

Figure 9.19: Manchester – Spring Street Parcel Map

Table 9.9: Manchester – Spring Street Station Area Evaluation

Category	Rating	Notes
Market	5	Located within downtown Manchester
Access	4	Indirect access from I-293, public parking garage nearby
Track	3	Curve in track, may require eliminating one or more grade crossings
Parcel	4	Tight space, may need surrounding properties for station
Land use	5	Existing commercial uses
Sensitive Receptors	4	Surrounding commercial buildings
Environmental	N	Nothing obvious
Ownership	P	Privately-owned railroad right-of-way

Assessment: Advanced

This site has the potential to operate as the downtown station for the City of Manchester. The recommended station design would construct an 800-foot long station platform on the east side of the tracks (see Figure 9.20 for the preliminary station design).

Figure 9.20: Manchester – Spring Street Preliminary Station Design

9.4 Concord Station Options

Figure 9.21 shows two potential station locations that could be implemented to serve the Intercity 8 option: Depot Street and Stickney Avenue.

Figure 9.21: Potential Concord Station Locations

9.4.1 Concord – Depot Street

The Depot Street location is the site of Concord's historic passenger rail depot that was demolished in 1960 (Figure 9.22). The site is a block from Main Street and a short walk to the State Capital. The former railway yard at this location, however, has been redeveloped as a strip mall with a large parking lot. Site features and challenges include the following (see Figure 9.23 for a parcel map, and Table 9.10 for summary evaluation ratings):

Figure 9.22: Historic Concord Rail Station

- Privately-owned site with active retail uses and proposed for redevelopment
- City of Concord officials are less interested in this site as a railway depot
- Nearby Liquor Commission Warehouse is being sold
- Land adjacent to I-93 has been identified by NHDOT for proposed highway widening and realignment

Figure 9.23: Concord – Depot Street Parcel Map

Table 9.10: Concord – Depot Street Station Area Evaluation

Category	Rating	Notes
Market	5	Close to downtown Concord
Access	5	Access from Main Street, could have access from I-93
Track	4	Slight curve in the track at this location, but enough straight tracks for platform
Parcel	5	Large enough to be suitable for redevelopment
Land use	4	Existing commercial development
Noise	5	Located between I-93 and commercial development
Environmental	N	Nothing obvious
Ownership	P	Privately-owned

Assessment: Eliminated

Local officials are more supportive of the nearby Stickney Avenue site where the railway station could be built on public land and would be much closer to the existing intercity bus terminal. Consequently, preliminary plans for the Depot Street site were not prepared.

9.4.2 Concord – Stickney Avenue

Stickney Avenue extends approximately 2,000 feet between I-393 and Loudon Road and runs parallel to I-93 and the PAR NHML. The railroad forks at this location several blocks north of the Depot Street site. NHML heads northwest toward Lebanon, White River Junction, Montpelier, and Montreal. The New England Southern Railroad (NEGS) branch diverges northerly towards the Lakes Region and the White Mountains. The NHML line is the former B&M line, now owned by the State of New Hampshire, and is the anticipated route of a restored passenger rail service between Boston and Montreal. The station design at this site should not preclude any future extension of passenger rail service along either branch.

Concord's state-owned intercity bus terminal is also located on Stickney Avenue. The City of Concord is interested in developing its passenger rail terminal on state-owned land immediately west of the bus terminal. The city is also planning to extend Storrs Street northward on the site's west side to connect with South Commercial Street and encourage site redevelopment. Plans for the terminal area need to reserve space to restore a run around track used by the NEGS that was removed but not replaced in the course of an abandoned project to build a hotel on the site. Site features and challenges include the following (see Figure 9.24 for a parcel map, Figure 9.25 for site photographs, and Table 9.11 for summary evaluation ratings):

- NHDOT planning to demolish former highway garage buildings on the site's east side
- Existing track spur creates constraints
- Ample vacant land for parking
- Direct access to I-93 (Exit 4)
- Intercity bus terminal is located at the furthest point from the existing rail line; it would be difficult to combine the two facilities

- Large U-Haul rental and self-storage facility located adjacent to the site and across from existing intercity bus terminal
- The Friendly Kitchen soup kitchen opened in a new purpose-built structure on the site's north end in late 2012
- Existing neighborhood:
    - Five houses on Herbert Street
    - One duplex on 6 Higgins Street
    - Homeless encampments and squatting in vacant buildings

Houses on Herbert Street

U-Haul rental and self-storage facility

Friendly Kitchen

Railroad right-of-way behind Friendly Kitchen

Table 9.11: Concord – Stickney Avenue Station Area Evaluation

Category	Rating	Notes
Market	5	Close to existing intercity bus terminal and P&R lot
Access	4	Close to I-393, but needs a more direct access point from I-393 and I-93; this would be solved with proposed reconstruction of I-93 and extension of Storrs Street
Track	3	Track realignment necessary due to proposed Storrs Street extension and to maintain freight access north of Concord
Parcel	5	Large site with flexibility and potential for redevelopment
Land use	5	Former NHDOT buildings
Sensitive Receptors	4	Adjacent to I-93, but proximate to commercial and residential uses
Environmental	Y	Potential remediation
Ownership	G	Government ownership

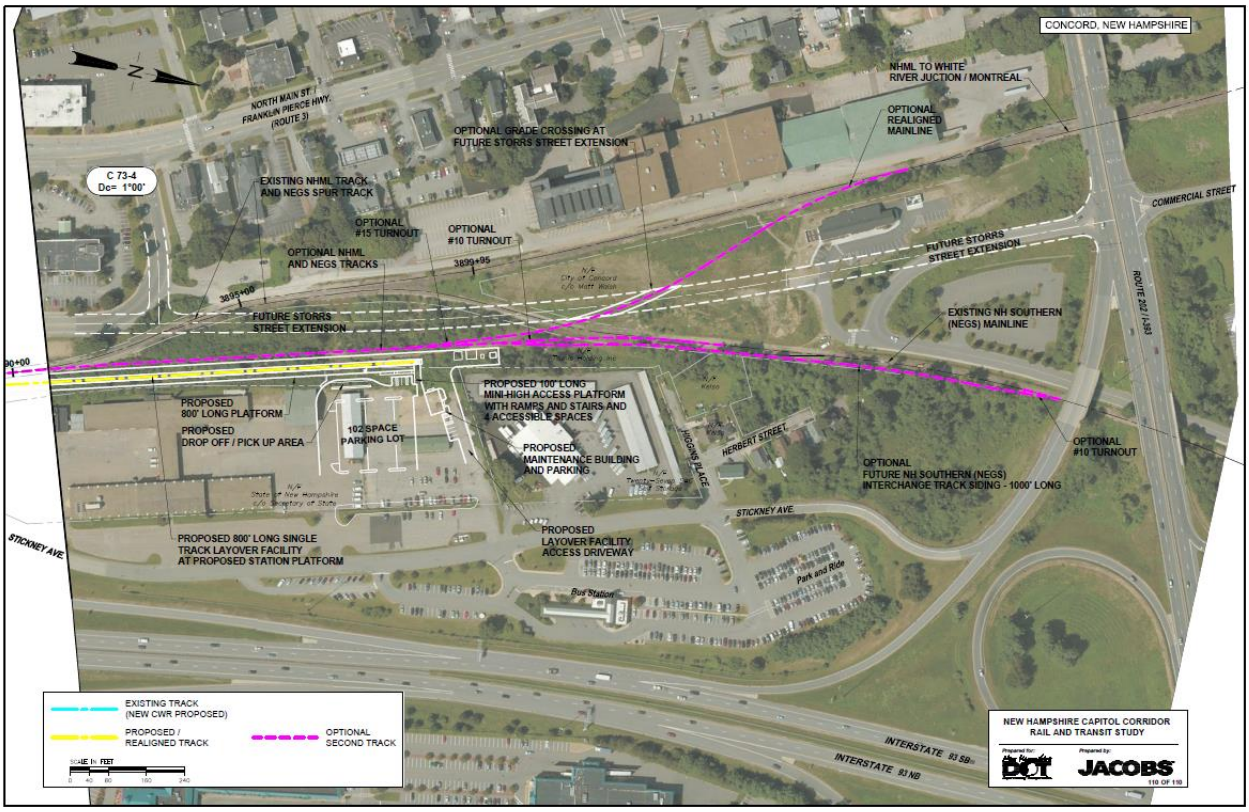
Assessment: Advanced

This Stickney Avenue site is highly rated as it could hold both a station and layover yard. The station would have one platform serving one or two tracks and the joint station/layover facility. Current requirements call for only one track, but with future expansion of intercity service, two storage tracks may eventually be required. A layover yard would be required at or near the terminus of the proposed Intercity 8 service option. The preliminary station design shows ample land within the larger site for construction of a railway station with parking, train layover on the station tracks or on an adjacent track, and an NEGS run around track while still allowing the City of Concord's redevelopment plans to proceed (see Figures 9.26 and 9.27 for extension plans, and Figure 9.28 for preliminary station and layover design).

Figure 9.26: City of Concord Storrs Street Extension Plans

Figure 9.27: Alternative City Plan for Storrs Street Extension

Figure 9.28: Concord – Stickney Avenue Preliminary Station and Layover Design



9.5 Evaluation of Station Sites

Table 9.12 summarizes evaluation criteria described earlier in this report that were used to guide the layover site selection process (the light gray shaded rows represent stations that were advanced for consideration). Criteria were given a rating of one for poorly performing sites to five for highly performing sites. The owner criteria was designated was designated G for government-owned or P for privately-owned, while the environmental criteria was designated as Yes or No.

The Beazer-East site in Nashua was eliminated from further consideration due to the nature of its poor relation to potential rail service, site access constraints, and existing soil contamination. The Queen City Avenue site was eliminated early in the site selection process due to its weak relationship to the existing downtown and distance from other transit services. Finally, the Depot Street site in Concord was eliminated because local officials are more supportive of the nearby Stickney Avenue site where the railway station could be built on public land and would be much closer to the existing intercity bus terminal.

Table 9.12: Site Evaluation Summary

	Market	Access	Track	Parcel	Land Use	Noise	Environmental	Ownership	Assessment
Nashua Sites									
Crown Street	4	4	5	4	5	3	Y	G	*Advanced*

Concord Sites									
Depot Street	5	5	4	5	4	5	N	P	Eliminated
Stickney Avenue	5	4	3	5	5	4	Y	G	*Advanced*

9.6 Cost Estimates

Capital cost estimates were developed for each of the advanced station sites using unit costs that were generated for a directly applicable peer site. The MBTA Fitchburg Commuter Rail-Wachusett Extension Project is currently underway and moving into construction. Detailed capital costs were prepared by Jacobs Engineering and partner Keville Enterprises, Inc. in January 2013. The estimated construction cost with escalations and contingencies came to $13,303,000 for a single-track siding station with one 800-foot high-level side platform and 360 parking spaces.

These detailed costs were used to inform cost estimates for each of the proposed station sites through the use of allocation factors: variables such as the number of parking spaces, number of platforms,

number of side tracks, square feet of existing wetlands, and the possibility of contaminated soils (see Table B-1 in Appendix B to this report). This allowed for the application of the Wachusett station unit costs even where characteristics of the sites were different. The costs for Pheasant Lane Mall include a parking garage that was estimated at 10 times the cost per space of a surface space. This figure is consistent with Jacobs estimates for other parking garages. The summary of unit costs is shown in Table 9.13, and a detailed accounting of the capital cost calculation is contained in Table B-2 in Appendix B to this report.

Table 9.13: Estimated Station Construction Costs for Intercity Passenger Rail Development

	Nashua Crown Street	Bedford/MHT	Manchester		Concord Stickney Avenue
			Granite Street	Spring Street	
MP	38.8	50.1	55.5	56.4	73.3
Parking	255	190	0	0	100
Platforms	1	1	1	1	1
Contaminated Soils	0.5	0	0.5	0	0
Square Feet of Wetlands	0	0	0	0	0
Side Tracks	0	0	0	0	0
Total direct cost	$4,212,500	$3,594,256	$2,761,239	$2,512,925	$3,082,046
Estimated contractor cost	$5,200,037	$4,436,858	$3,408,557	$3,102,030	$3,804,571
Estimated contractor allowances	$987,537	$842,602	$647,318	$589,105	$722,525
Escalation to Oct 2013 (3.8%/year)	$226,747	$193,346	$152,938	$138,351	$167,296
Escalated estimated construction cost	$5,730,308	$4,886,203	$3,865,020	$3,496,381	$4,227,866
Construction contingency	$573,030	$488,620	$386,501	$349,638	$422,786
Estimated construction cost	**$6,303,339**	**$5,374,824**	**$4,251,522**	**$3,846,019**	**$4,650,653**

Unit cost resources: MBTA Fitchburg Commuter Rail-Wachusett Extension Project: PS&E Construction Estimate; Jacobs/Keville Enterprises, Inc.; January, 2013

Beyond the railroad right-of-way that will be shared with PAR freight trains, land will be required for stations facilities and parking. The cost for this land was estimated by consulting local public assessor records in Tyngsborough, Nashua, Bedford, Manchester, and Concord to determine the current assessed value of each parcel that had been identified as necessary for a station (see Table B-3 in Appendix B). Where only a portion of the parcel would be required for the rail facility, GIS tools were used to determine what fraction of the overall parcel would be necessary and to prorate the cost accordingly.

Acquisition of private land for transportation improvements can be a litigious process. The summary of estimated land costs in Table 9.14 includes an allowance of 220 percent to account for negotiations, takings, eminent domain, and legal costs. The 220 percent was derived from the Study team's experience working on similar projects in other jurisdictions, but it is possible that New Hampshire's experience may be different.

Table 9.14: Assessed Land Value and Estimated Cost for Selected Station and Layover Sites

	Parcel Size (Acres)	Required Portion	Assessed Value per Acre	Estimated Value	Estimated Cost with 220% Assemblage Factor
Crown Street	6.826	1.0	$ 45,224	$308,700	$987,840
Bedford/MHT	6.000	0.33	$ 29,416.67	$444,400	$1,422,080
Granite Street	0.5544	1.0	$ 279,132.58	$148,800	$476,160
Stickney Avenue	6.08	1.0	$ 237,990	$1,447,000	$4,630,400

9.7 Station Recommendations

Stations at ***Crown Street*** in Nashua and the ***Bedford/Manchester Airport*** site below Ray Wieczorek Drive are recommended for the Intercity 8 service option. The station site at ***Granite Street*** in Manchester is favored over the Spring Street/Bridge Street site as it provides better access to Route 3 and the existing intercity bus terminal. Finally, a station at ***Stickney Avenue*** in Concord is recommended for the intercity rail service.

9.8 Layover Facilities

This section describes potential sites for overnight storage and servicing of the intercity rolling stock in the vicinity of the proposed northern terminus in Concord.

9.8.1 Layover Design Requirements

Wherever the eventual layover facility is located, the project would need to provide a small railroad yard capable of storing 1,000-foot long train sets (one locomotive and up to nine coaches allowing for service expansion). Only one track would be required for the Intercity 8 service. Three potential locations in Concord were identified for a layover facility for overnight storage and light servicing for one train set with expansion space for at least one additional train set:

- Langdon Avenue Industrial Area
- Depot Street
- Stickney Avenue

A crew building would be required at each site and include a materials and equipment storage locker for mechanical personnel to store cleaning and maintenance materials onsite and perform running repairs on equipment. The facility's entrance would be paved, and have parking for a minimum of six cars. There would be 20-foot wide service lanes located on at least one side of each track with 4-foot-wide walkways built between the tracks. High-mast lighting with walkway lights would be located in the service walkways. The entire layover facility should be fenced in, and, if necessary, noise walls could be constructed at additional expense beyond preliminary cost estimates.

Spill pans would be required under the locomotive (northern) end of each track, complemented by oil/water separators. Near the track's locomotive, air compressor and electric power hookups would be required so that locomotives could be shut down while still allowing for lights and HVAC in the coaches.

These power and air connections would eliminate the need for locomotives to do a cold startup each morning. Two separate small buildings housing the power and air compressor would be required. Potable water along the tracks and sanitary service equipment would also be provided onsite. An inspection pit located under the yard lead, prior to the ladder leading towards the tracks, would also be desirable.

9.8.2 Site Evaluation Criteria

In addition to ensuring that a site is of sufficient size and of a suitable configuration to support storage and maintenance, overnight noise is the overwhelming consideration in the siting of commuter rail layover facilities. Engines in the yard will need to be started at least 30 minutes before the first southbound train, and the last train engine to pull into the layover yard would be shut down approximately 30 minutes after arrival of the last train of the night (see Table 9.15). At Concord, locomotives would power up before 6:30am and be powered down after midnight.

Table 9.15: First and Last Trains of the Day at Concord for the Intercity Service

Time of First Morning Train	Time of Last Evening Train
6:38 am	11:37 pm

A diesel locomotive can often be as loud as a jackhammer when pulling or pushing a string of cars and approximately as loud as a lawnmower while idling. Nighttime noise is the number one source of complaints relative to layover facilities. Given these characteristics, an acceptable site must be distant from homes, hospitals, and other sensitive receptors. Sites with the lowest levels of complaints tend to be at locations where there is already a high-level of ambient noise, such as on the skirt of a busy highway.

The following list of evaluation criteria was developed to guide the layover site selection process. The evaluation criteria measures were given a rating of one for poorly performing sites to five for highly performing sites. The environmental criteria were designated as Yes or No, while the ownership criteria was designated G for government-owned or P for privately-owned.

1. Terminus
    - Does the site adequately serve the proposed rail service options with northern terminals in Concord?
    - What are deadhead cost savings and travel time efficiencies?
2. Track Operational Characteristics
    - Is the track straight and free of existing sidings?
    - Are there any grade crossings adjacent to the site?
    - Is there a requirement for new traffic/train signals?
    - Are any bridge structures required for roadway access or yard leads?
    - Are freight train movements/clearances maintained?

3. Access
    - Would new roads be required for access for staff and deliveries?
    - Are local roadways compatible with the site to allow yard movements efficiently in a manner that would not extensively conflict with local roadways?
4. Parcel Size/Configuration
    - Is there adequate land available for layover tracks and maintenance facilities?
    - Would displacement of residents/businesses be required?
5. Land Use
    - Is the site currently zoned for industrial or compatible land uses?
    - What are the predominant surrounding land uses?
    - What are municipality and community aspirations/priorities?
    - Are there any environmental justice issues, including possible impacts on minority populations and low-income households?
6. Sensitive Receptors
    - Are there any residential buildings or educational, medical, or religious facilities near the site that would have a heightened sensitivity to noise or vibration impacts?
7. Environmental
    - Is the site adjacent to a river or within a flood zone?
    - Is the site in or adjacent to jurisdictional wetlands?
    - Does the site have a history of contamination?
    - Has the site been designated as a threatened or endangered species habitat?
8. Ownership
    - Is the property owned by state or local government or is it privately held?
    - Is the property for sale, single-owner or multiple, publicly owned land?
    - What are potential land acquisition costs based on assessed value per acre?
    - Would there be relocation costs resulting from displacement of residents/businesses?

9.8.3 Preliminary Layover Facility Sites

Based on field inspections, interviews with local officials, and review of earlier studies, three potential sites were identified for the Concord layover facility. The evaluated sites are listed in Table 9.16. Several tentative sites were eliminated very early during the preliminary assessment, while three were advanced for formal preliminary evaluation.

Table 9.16: Potential Concord Layover Facilities

Sites Evaluated	MP
Langdon Avenue Industrial Area	72.0
Depot Street	72.6
Stickney Avenue	73.3

Once the layover facility sites were identified, schematic designs were overlaid on annotated aerial imagery prepared by Jacobs Engineering in September 2013. These schematic designs include tracks, switches, platforms, roadways, pathways, parking, circulation, buildings, and other related features. Parcel mapping information provided by the municipalities and NHDOT was also included in the schematic designs. It will be necessary for the designs to be reviewed by Amtrak, MBTA, PAR, NHDOT, and other stakeholders before being finalized.

The following sections describe and document each layover facility site with findings from the initial site review. Parcel mapping, site photos, and earlier plans (where appropriate) and preliminary schematic designs are included for environmental and financial review.

9.8.4 Concord Layover Facility Options

Figure 9.29 shows the location of the three potential layover yards that could be implemented to serve the Intercity 8 option: Langdon Avenue Industrial Area, Depot Street, and Stickney Avenue.

Figure 9.29: Potential Concord Layover Yard Locations

Concord: Langdon Avenue Industrial Area

The industrial area located near Langdon Avenue in Concord is 1.3 miles south of the proposed Stickney Avenue terminal station could be developed as a layover yard. Table 9.17 summarizes the evaluation.

Table 9.17: Evaluation of Langdon Avenue Layover Facility

Category	Rating	Notes
Terminus	4	Over one mile south of the proposed Concord terminal station at Stickney Avenue
Track	5	Long, straight track section
Access	4	Access to South Main Street via Lehoux Ave.
Parcel	4	Adequate space for storage tracks and facilities
Land Use	5	Vacant/existing industrial uses
Sensitive Receptors	2	Nearby residential neighborhood
Environmental	N	Nothing obvious
Ownership	P	Privately-owned

Assessment: Eliminated

The site lies within 1,000 feet of residential neighborhoods west of Main Street and development would require the taking of privately-owned land. The availability of land to develop a combined station and layover yard at Stickney Avenue eliminated this site from further consideration.

Concord: Depot Street

This state-owned parcel near Depot Street and adjacent to I-93 would make an ideal site for a layover yard since the busy highway would help attenuate the sound of the trains overnight. Table 9.18 summarizes the evaluation.

Table 9.18: Evaluation of Depot Street Layover Facility

Category	Rating	Notes
Terminus	5	One-half mile south of the proposed Concord terminal station at Stickney Avenue
Track	4	Straight track section, former rail yard
Access	4	Access to Storrs Street via mall parking lot access roads
Parcel	4	Adequate space for storage tracks and facilities, located between existing strip mall and I-93
Land Use	5	Vacant/transportation/existing commercial uses
Sensitive Receptors	5	Adjacent to I-93 and removed from downtown Concord
Environmental	N	Nothing obvious
Ownership	P	Privately-owned railroad right-of-way

Assessment: Eliminated

The city and state have other development plans for this site, which is located one-half mile south of the proposed Stickney Avenue terminal station, so it was eliminated from further consideration.

Concord: Stickney Avenue

This option would co-locate the layover facility with the proposed station on a state-owned parcel near the existing intercity bus terminal. As noted earlier in this section, Stickney Avenue extends approximately 2,000 feet between I-393 and Loudon Road and runs parallel to I-93 and PAR NHML. The railroad forks at this location, which is several blocks north of the Depot Street site. The NHML heads northwest toward Lebanon, White River Junction, and Montpelier, and is the anticipated route of a restored passenger rail service between Boston and Montreal. The NEGS branch diverges northerly towards the Lakes Region and the White Mountains. The design of the layover facility at this site should not preclude any future extension of passenger rail service along either branch. See Table 9.19 for an evaluation summary.

The Study team determined that the Intercity 8 option would require overnight storage for only one train set and that the train could be stored and serviced at the Concord terminal station. This would be consistent with current practice for the *Downeaster* operations in both Portland and Brunswick, Maine and other minor intercity rail services such as Oklahoma City's *Heartland Flyer*. This site and the proposed station were discussed extensively earlier in this section.

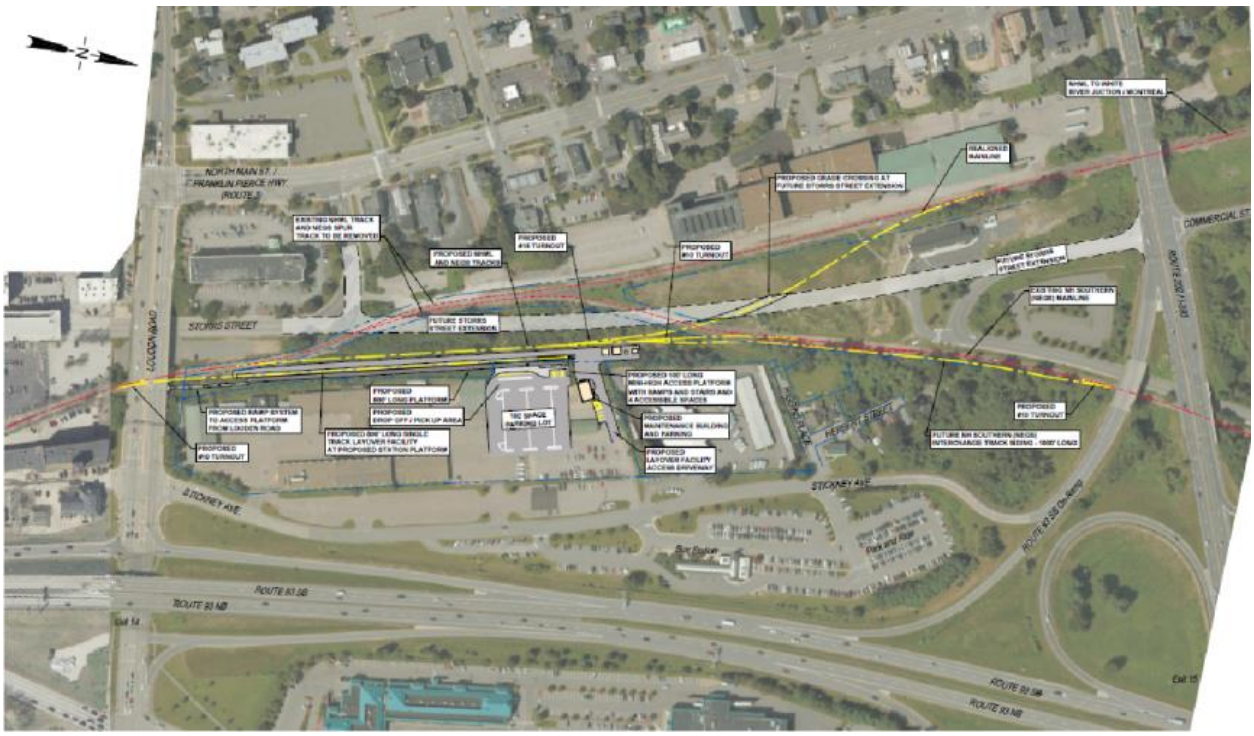
Table 9.19: Evaluation of Stickney Avenue Layover Facility

Category	Rating	Notes
Terminus	5	Co-located with proposed Concord terminal station at Stickney Avenue
Track	3	Track realignment necessary due to proposed Storrs Street extension and to maintain freight access north of Concord
Access	5	Access via Stickney Avenue
Parcel	5	Adequate space for storage tracks and facilities
Land Use	5	Former NHDOT buildings
Sensitive Receptors	4	Adjacent to I-93, but proximate to commercial and residential uses
Environmental	Y	Potential remediation
Ownership	G/P	Government-owned parcels and privately-owned railroad right-of-way

Assessment: Advanced

This site is highly rated as it could accommodate both a station and layover yard. Current requirements call for only one track, but two storage tracks may eventually be required with the future expansion of intercity service. The station would have one platform serving one or both tracks and at the joint station/layover facility. Preliminary design shows ample land within the larger site for the construction of a railway station with parking, train layover on the station tracks or on an adjacent track, and a NEGS run around track – and still allow for the City of Concord's redevelopment plans to proceed. Figure 9.30 shows the preliminary station and layover facility design.

Figure 9.30: Concord – Stickney Avenue Preliminary Station and Layover Design



9.8.5 Evaluation of Layover Facility Sites

Table 9.20 summarizes the evaluation criteria used to guide the layover site selection process. Criteria were given a rating of one for poorly performing sites to five for highly performing sites. The owner criteria was designated was designated G for government-owned, P for privately-owned or ROW for railroad right-of-way, while the environmental criteria was designated as Yes or No.

The Langdon Avenue site and the Depot Street site in Concord were eliminated because local officials are more supportive of the nearby Stickney Avenue site where the railway station could be built on public land and would be much closer to the existing intercity bus terminal.

Table 9.20: Concord Layover Site Evaluation Summary

	Terminus	Track	Access	Parcel	Land Use	Sensitive Receptors	Environmental	Ownership	Assessment
Langdon Avenue Industrial Area	4	5	4	4	5	2	N	P	Eliminated
Depot Street South	5	4	4	4	5	5	N	ROW	Eliminated
Stickney Avenue	5	3	5	5	5	4	Y	G	Advanced

9.8.6 Cost Estimates

Costs to develop layover yards for overnight storage and light maintenance of the service rolling stock were estimated for the one site that advanced through preliminary evaluation (Table 9.21). Estimates relied on unit costs recently generated by Jacobs Engineering for a directly applicable peer site. The MBTA Fitchburg Commuter Rail-Wachusett Extension Project is currently underway and moving into construction. The estimated Wachusett layover construction cost with escalations and contingencies came to $13,303,000 for a layover facility with six tracks, including 9,655 track-feet available for the storage of trains.

These detailed costs were used to inform cost estimates for each of the proposed layover facility sites through the use of allocation factors. These allocation factors included variables such as the number of storage positions, total track length (feet), and the possibility of contaminated soil disposal. This allowed for the application of the Wachusett layover facility unit costs even where the characteristics of the sites were different. The summary of unit costs is shown in Table C-1 in Appendix C. Detailed capital cost calculations are documented in Table C-2 in Appendix C.

Table 9.21: Estimated Layover Facility Capital Costs (2013$)

MP	73.3
Number of storage positions	1
Total track length (feet)	800
Possibility of contaminated soils	1
Total direct cost	$3,100,795
Estimated contractor cost	$3,827,716
Estimated contractor allowances	$737,600
Escalation to Oct 2013 (3.8%/year)	$188,091
Escalated construction cost	$4,753,407
Construction contingency	$475,340
Estimated cost with contingency	**$5,228,747**

Source: MBTA Fitchburg Commuter Rail-Wachusett Extension Project: PS&E Construction Estimate; Jacobs/Keville Enterprises, Inc.; January, 2013

Beyond the railroad right-of-way that will be shared with PAR freight trains, additional land will be required for layover yards. The cost for this land was estimated by consulting local public assessor records in Concord to determine the current assessed value of each parcel that had been identified as necessary for a layover yard (see Table C-3 in Appendix C). Where only a portion of the parcel would be required for the rail facility, GIS tools were used to determine what fraction of the overall parcel would be necessary and to prorate the cost accordingly.

Acquisition of private land for transportation improvements can be a litigious process. The summary of estimate land costs in Table 9.22 includes an allowance of 220 percent to account for negotiations, takings, eminent domain, and legal costs. The 220 percent was derived from the Study team's

experience working on similar projects in other jurisdictions, but it is possible that New Hampshire's experience may be different.

Table 9.22: Assessed Land Value and Estimated Cost for Concord Layover and Station Site

Site	Parcel Size (Acres)	Assessed Value per Acre	Estimated Value	Estimated Cost with 220% Assemblage Factor
Stickney Avenue	6.08	$ 237,990	$1,447,000	$4,630,400

10 Preferred Intercity Rail Required Capital Improvements and Capital Costs

10.1 General Infrastructure Requirements

To build Intercity 8, the Study team consulted with MassDOT, MBTA, and PAR and determined that no improvements would be required south of MBTA's Lowell Gallagher Terminal. North of Lowell the railroad would be upgraded to permit safe, reliable operation of eight daily passenger trains at speeds of up to 75 mph. Recommended upgrades to track, bridges, crossings, and signals are summarized below.

The Intercity 8 service option would require more extensive infrastructure upgrades than the proposed commuter rail options as it is approximately 18 miles longer than the Manchester Regional Commuter Rail service. The service would also operate at higher maximum speeds: up to 75 mph between Nashua and Bedford/Manchester Airport and 70 mph north of Manchester.

10.1.1 Track

Study team engineers had originally recommended that this option be supported by replacing all 70-plus-year-old main line rail between Lowell and Concord with new continuous welded rail (CWR) of a similar weight. The infrastructure requirements for each of the three remaining rail options were revisited in meetings with PAR, MassDOT, MBTA, and NHDOT as the Study progressed. The Study team refined the preliminary infrastructure requirements based on their feedback and with the aid of two Hi-Rail trips along the corridor with railroad officials. Principal adjustments in the track upgrades necessary for Intercity 8 service include the following:

- Reconsidered needs and limits of industrial freight sidings designed to avoid conflicts with passenger trains. MP locations denote distance from Boston North Station. Required sidings:
    - Nashua Corporation (B41.8 to B42.5)
    - Anheuser-Busch (B43.8 to B44.8)
    - Merrimack Running Track/Jones Chemical (B45.6 to B47.9)
    - Public Service of New Hampshire Receiving Track (B66.4 to B 68.5)

- Reappraisal of existing track conditions to reduce required track upgrades:
    - Replace only one-third of all ties due to better-than-anticipated tie conditions. One-half of all ties had initially been slated for replacement at Study outset.
    - Retaining or relaying existing rail on tangent track and industrial sidings instead of replacing all rails to utilize all life left in existing rail and minimize initial required capital outlays. Relay and retained rail would need to be replaced in a multi-year program that would begin approximately 10 years after start-of-service.

PAR supplied more detailed data on bridge conditions, track conditions, crossings, and other infrastructure in March of 2014. Using this information together with field inspections of track, crossings, and selected bridges, Study team engineers assembled more detailed evaluations of the conditions of existing assets and revised their cost estimates accordingly.

The track configuration necessary to support the Intercity 8 service was identified by inspection of the time-distance stringline diagrams, considering the timing and nature of freight uses on the line.

- Between Boston and Lowell, the line is busy with passenger service, but has only limited unscheduled local freight service. No upgrades to the well-maintained, double-track rail network would be required along this segment.
- Between Lowell and North Chelmsford, the line is a segment of PAR's east-west main line. This three-mile segment of double-tracked railway carries up to eight through-freight trains and several local freight trains each day. Threading eight non-stop intercity trains through this short double-track segment should not prove challenging.
- From North Chelmsford to Concord, the line is 45 miles of mostly single track. Segments of second main line track are recommended through yards in Nashua and Manchester. Industrial sidings are recommended at locations where local trains stop to serve customers. Industrial sidings will keep local freight trains from blocking the main while they serve customers.

The proposed track configuration is shown in Figure 10.1. No improvements are recommended for the tracks shown in black. Rail and ties will be replaced or renewed on existing tracks shown in green. Red tracks and switches represent new construction.

Unlike the higher frequency commuter rail options, no double track would be required between North Chelmsford (MP 28.5) and the southern end of the Tyngsborough Curve (MP 32). As noted above, industrial sidings would be created at three key areas of freight activity in Nashua and Merrimack to eliminate conflicts between local freight deliveries and through passenger trains. At these locations, the existing main line track would be retained as an industrial siding with an entirely new parallel main line

track constructed in the same alignment for use by through trains. Adding a second track would be straight-forward, as the railway was once entirely double-tracked with the double-track bed still largely intact.

10.1.2 NHML Track Profile, Alignment, and Maximum Allowable Speeds

The NHML north of Lowell to Concord runs along the banks of the Merrimack River. This alignment has mostly gentle grades, with none steeper than 0.35 percent. The horizontal alignment curves to follow the river with few tangent (straight) segments more than one-mile long. Between Lowell and Concord, 29.6 of the 48.5 track miles are curved. This constitutes 61 percent of the route. Many of the curves are sufficiently tight to impact maximum train speeds. The engineering required to achieve trains speeds of 80 mph or higher is substantially more challenging when the radius of the railway curve is less than 3,820 feet (1.5 degrees of curvature). Between Lowell and Concord there are 19.6 miles of such restrictive curves, which constitute 40 percent of the route miles.

As noted earlier, the maximum historic passenger speed along the NHML was 70 mph. This reflects what clearly had been a long and careful analysis balancing the desire for passenger speed with maintenance costs, safety, and freight economy. The calculation of maximum speeds through tight curves on tracks shared with freight trains involves a number of factors. Freight trains place operational and physical limits on maximum passenger train speeds through curves on tracks shared by freight and passenger trains. To ensure passenger comfort and safety through curves at higher speeds, tracks can be banked or *superevelated*. The extent of the bank is measured in inches reflecting the difference in elevation between the outside rail and its corresponding inside rail along the curve. With increased train speeds and sharper curves, more superelevation is required. However, when heavy freight trains move slowly (or stop) along a curve with high superelevation, the weight of the train can put unacceptable stresses on the curve's lower inside rail. Consequently the maximum speed for a passenger train through a curve that is shared with freight trains is limited by the physical and operational demands of the freight service.

Passenger trains often run through curves at speeds that generate centrifugal forces somewhat greater than that compensated by the superelevation. In these circumstances, known as *underbalance*, the train and passengers tend to sway toward the outside of the curve. Using underbalance elevation in the geometric design of curves allows both a nominal amount of sway, considered safe and acceptable practice, and alleviates some of the undue weight that heavy freight trains place on the low rail through the curves. A few specifics concerning the process of mathematically balancing freight and passenger train requirements are provided in the following paragraphs.

Concerning Railway Curve Design

Finding the right mix of superelevation and underbalance on curves is referred to as Equilibrium Elevation or Ee and is calculated by factoring the square of the speed, the degree of the curve, and a derived constant value of 0.0007, shown in written form as $Ee = 0.0007 \times Dc \times V^2$. Once Ee is found, its value is split between the sum of Ea (actual superelevation) and Eu (underbalance or unbalance elevation), shown in written form as Ee = Ea + Eu. The amount of actual elevation sets the maximum amount of cross-level that is tolerated as a train stands on the curve. Unbalanced elevation sets the

amount of residual centrifugal force or sway that is tolerated as the passenger train traverses the curve at maximum speed.

Maximum values for Eu and Ea are guided by the American Railway Engineering and Maintenance-of-Way Association (AREMA), but the controlling railway authority generally dictates its own standards within AREMA guidelines.

- Underbalance (Eu) – Maximum values for Eu are typically three inches for passenger trains traveling on shared track.[26] MBTA tries to use a more conservative value for the amount of unbalanced (deficiency) elevation allowed, using 1.5 inches as the preferred limit and allowing up to 2.75 inches as a maximum. This provides improved passenger comfort, better compatibility with freight operations, and a margin below the FRA-mandated three-inch maximum.[27] A three-inch maximum is used in this analysis.
- Actual Elevation (Ea) – MBTA limits Ea to a maximum of six inches, but recommends that Ea be limited to four inches on shared use track.[28] "Maximum Ea shall be six inches except it is desirable to limit Ea to four inches on routes where through freights operate and where trains are likely to stop or operate below the design speed on a regular basis." Amtrak track design standards allow an Ea maximum of six inches for passenger-only track, but face similar constraints as MBTA when sharing track with heavy freight trains.[29]

Using the strictest design guidelines of Max Ea = 4 and Max Eu = 2.75, Table 10.1 shows how the maximum allowable passenger speed decreases as a function of increasing curvature. Also note that passenger trains speeds of 80 mph cannot be sustained on shared track on curves greater than 1.5 degrees. However, as is often the case, design standards and other criteria used to determine geometric railroad alignments can be relaxed or otherwise modified, depending on numerous factors, including operational and maintenance input from predominate users. Other wayside factors like crossings, adjacent curves, station platforms, average train speeds vs. posted zone speed, yard limits, train make-up and equipment types, bridge/culvert conditions, and other physical constraints also need to be considered in setting superelevation and train speeds during final track design.

4.0	1,433	49
4.5	1,274	46
5.0	1,146	44
5.5	1,042	42
6.0	955	40
6.5	882	39
7.0	819	37

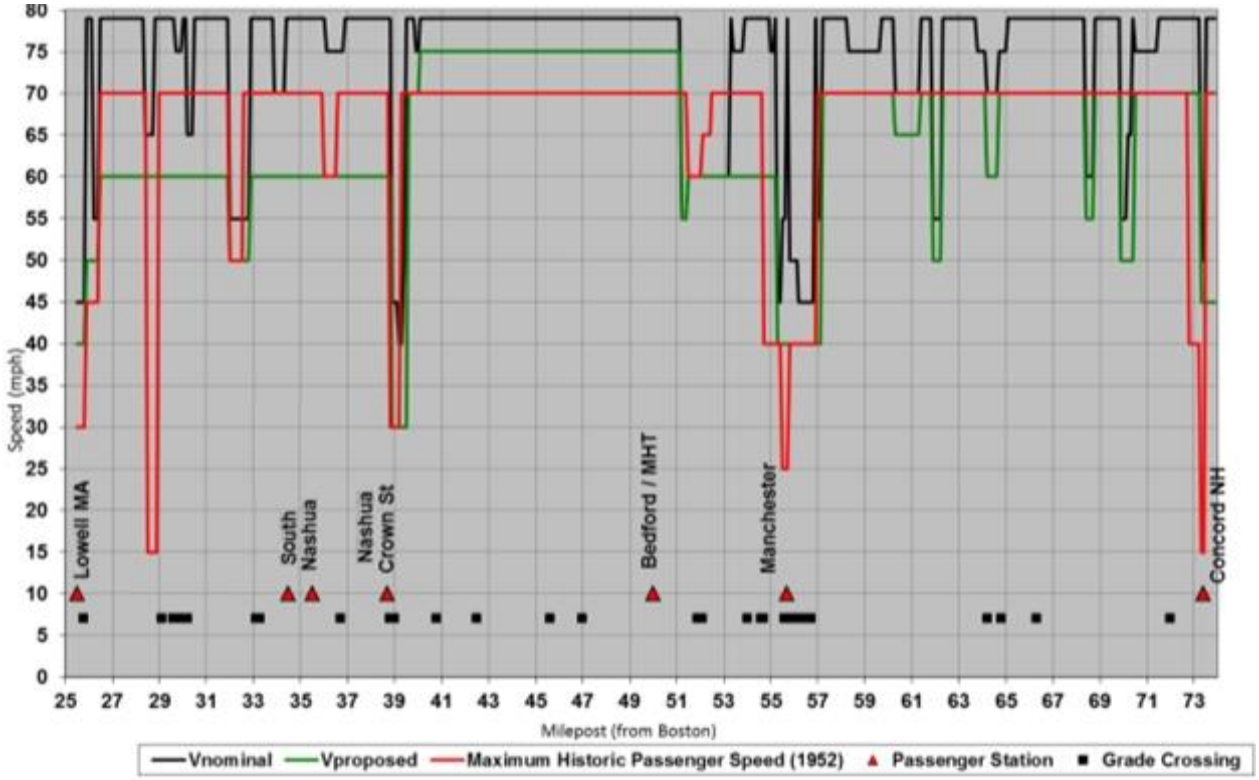
10.1.3 Setting New Passenger Speeds on the NHML

An inventory and geometric analysis of the existing main line horizontal curvature was prepared to evaluate the restoration of passenger rail service on the NHML north of Lowell to Concord, New Hampshire with Class 4 speeds. The following three vectors were computed for the 48.5 miles of new passenger railroad using the formulae described above.

- **Vnominal:** Shows the maximum allowable Class 4 passenger speed at all points along the line assuming the least restrictive criterion of Max Ee = 9 is applied (Ea = 6, Eu = 3)
- **Vproposed**: Is manually derived from Vnominal to smooth out speed limits and keep the value of Ea under five inches
- **Ea based on Vproposed**: Is the calculated superelevation (Ea) at each point along the railway necessary to support Vproposed

Figure 10.2 compares the values of Vnominal and Vproposed with historic maximum speeds along the NHML before FRA established maximum values for Ea and Eu. The maximum allowable speed in miles per hour is plotted on the Y-axis and the distance in miles from Boston is plotted on the X-axis.

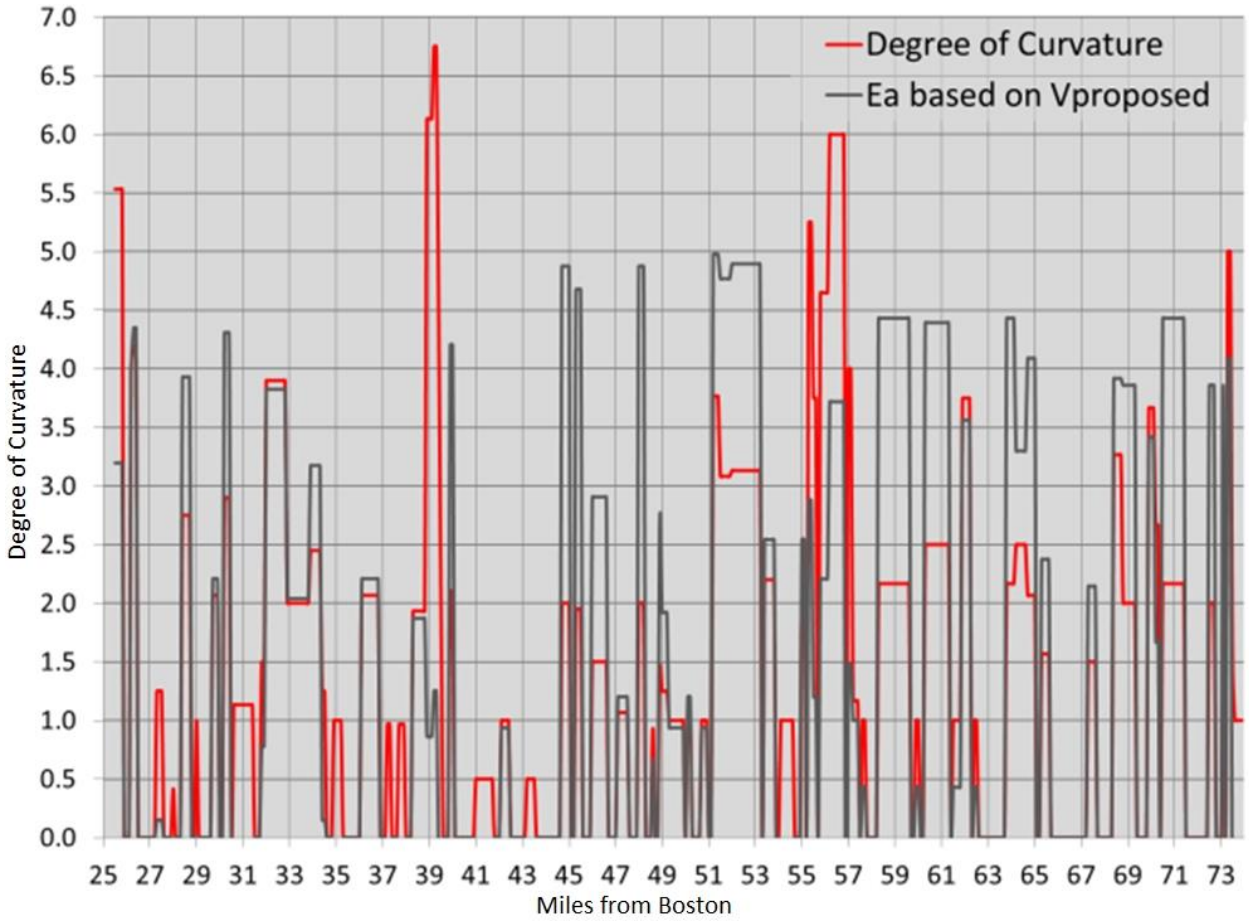
Figure 10.2: Historic, Nominal and Proposed Speed Profiles for NHML from Lowell to Concord



The proposed maximum speed profile for passenger trains would generally provide for maximum speeds of 60 mph northward to Nashua, then 75 mph to Bedford/Manchester Airport and 60 mph to Manchester. North of Manchester the maximum passenger speed would be 70 mph with five areas of speed restrictions as low as 50 mph. The proposed speeds (Vproposed) are in some cases less than the historic maximum speeds that required superelevation and underbalance standards in several areas not possible in the 21st century. The proposed speeds are also generally below the maximum allowable passenger speed to keep the required superelevation below five inches.

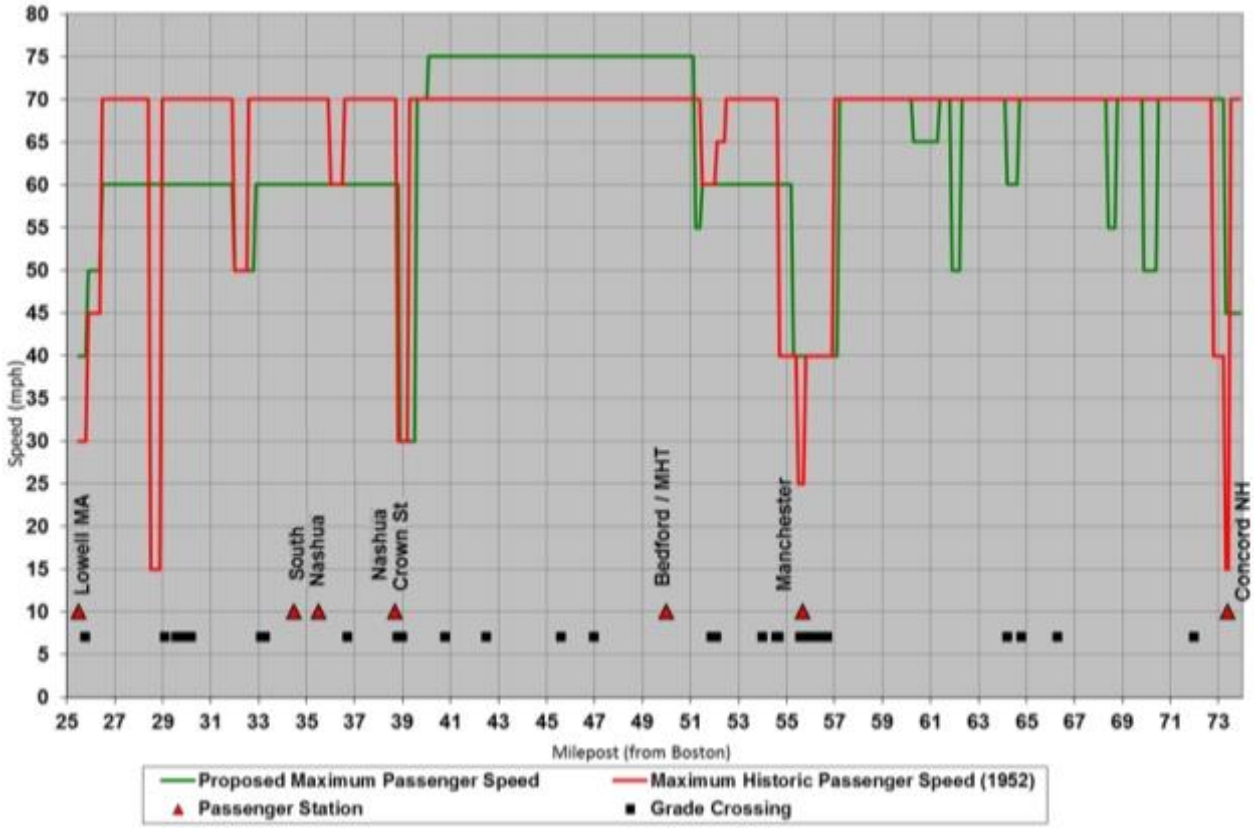
Figure 10.3 shows the degree of curvature and superelevation inches at each point along the rail corridor that would be necessary to support the speed profile described by Vproposed. In no case is the proposed superelevation in excess of five inches. A total 6.5 miles of track with superelevation greater than four inches, but less than five inches, is necessary to support Vproposed speeds. This track with high superelevation would constitute 13 percent of the route between Lowell and Concord.

Figure 10.3: NHML Curvature and Proposed Superelevation



In summary, the Study team's evaluation of tradeoffs between speed and maintenance expense suggest that the railway can be economically restored to a 60 mph (FRA Class 3) passenger speed standard for most of its length with only a few geometrically imposed speed restrictions. FRA Class 4 operations allowing a 75 mph maximum speed may be economically achievable between the Nashua River and the point where the railway crosses the Merrimack River into Manchester. North of Manchester some substantial segments of 70 mph may be achievable for a modest increase in capital cost and maintenance expense (see Figure 10.4).

Figure 10.4: Historic and Proposed Speed Profiles for NHML from Lowell to Concord



With these track improvements in-place, the Study team's analysis indicates that travel times of 89 minutes for the 73 miles between Concord and Boston would be achievable making intermediate stops at Manchester, Bedford/Manchester Airport, Nashua, Lowell, and Woburn.

10.1.4 Estimated Costs for Track Upgrades

Study team engineers developed cost estimates of the various necessary upgrades using information from current and recent passenger rail development projects elsewhere in New England together with inventory prices from MBTA's commuter rail department.

10.1.5 New and Rebuilt Track

Costs for labor and materials for new and rebuilt track were developed using track construction metrics, costs on MBTA's recent and current work improving its line to Fitchburg, and current prices for materials in the MBTA/Massachusetts Bay Commuter Railroad Company (MBCR) inventory system. The length in miles of new and rebuilt track required for each service option is summarized in Table 10.2.

Table 10.2: Estimated Miles of New and Rebuilt Track by Type of Rail for Intercity 8 Service

Replace Rail with CWR	Replace Rail with Relay Rail	New Track with CWR	New Track with Relay Rail
26.1	27.0	4.6	6.8

Retaining or relaying ('Relay') existing rail from another location on tangent track sections and industrial sidings instead of replacing all rails can maximize the lifespan left in existing rail and minimize initial required capital outlays. Relay and retained rail would need to be replaced in a multi-year program that would begin approximately 10 years after start-of-service. Cost parameters for new and rebuilt track are summarized in Table 10.3.

Table 10.3: Cost Parameters and Unit Costs (2014$) for New Track

Cost Element	Quantity	Unit Cost	Subtotal	Source
Cost of New Track (New 115# CWR)			$1,155,088/mile	$218.77/foot
Materials			$616,894	
Wood ties	3,249	$47.21	$153,396	MBCR Inventory Value
Ballast (tons)	1,500	$33.64	$50,460	Fitchburg Main Line (ML) Improvement Project

10.1.6 Track Switches

The need for new and renewed switches in the track structure was identified as the track configuration was finalized for each option. Costs for new switches were derived using reported costs for installed switches on MBTA's ongoing Fitchburg Line Improvement Project. Switch renewals were estimated at two-thirds of the installed cost for an entirely new switch. New and renewed switches for Intercity 8 is listed in Table 10.4.

Table 10.4: New and Renewed Switches for Intercity 8 Option

Switch Location and Type	Installed Cost (2014$)	Quantity
New #15 Crossover (B25.8)	$632,475	1
Renew #15 Crossover (B25.9)	$421,650	1
New #15 Turnout (CPF-NC*)	$316,238	1
Renew #15 Turnout (CPF-NC)	$210,825	1
New #15 Crossover (B29)	$632,475	1
New #10 Turnout (B29.7) Courier Corp	$184,000	1
New #20 Turnout (B32.1) Tyngsborough Curve	$434,526	1
New #15 Turnout (B34.2) to Layover Facility	$316,238	1
Renew #15 Turnout (CPN9)	$210,825	1
Renew #15 Crossover (B37.9) Robies	$421,650	1
Renew #15 Turnouts Nashua Yard/Station (B38.7)	$210,825	1
New #10 Hand Throw (B42.3) Nashua Corp Siding	$184,000	2
Renew #10 Turnout to Nashua Corp	$122,667	2
New #10 Hand Throw (B43.5) Anheuser Busch	$184,000	2
Renew #10 Turnout (B43.6) Anheuser Busch	$122,667	1
New #15 Turnout (B45.4) Merrimack Running Track	$316,238	1
New #10 Hand Throw (B45.6) to NE Pole Siding	$184,000	1
Renew #10 Hand Throw (B46.1) Jones Chemical	$122,667	1
Renew #15 Turnout (B47.8) CPN 20	$210,825	1
Renew #10 Turnouts to Manchester Customers	$122,667	1
Renew #15 Turnout (B55.3) Manchester Yard	$210,825	1
New #15 Turnout (B55.6) to Layover Facility	$316,238	1
New #15 Turnout (B55.7) CPN 28 to Concord	$210,825	1
Renew #10 Hand Throw (B66.1) Cement Quebec	$122,667	1
Renew #15 Turnout (B66.4) Perini Siding	$210,825	1
Renew #10 Hand Throw (B67) Coastal Wood	$122,667	1
New #10 Hand Throw (B68) PSNH Siding	$122,667	1
Renew #15 Turnout (B72.7) Concord Yard	$210,825	1
Renew #10 Hand Throw (B73) Scrap Yard	$122,667	1
New #15 Turnout (B73.3) Loudon Rd/Concord Station	$316,238	1
**CPF-NC = Control Point: Freight Main Line – North Chelmsford*		

Interlockings and Block Signals

The NHML has a fully functioning Centralized Traffic Control (CTC) signal system in-place between Lowell and CPN28 in Manchester that would be renewed and upgraded for the new passenger service. Existing block signals were identified by reference to PAR documentation. New and renewed interlockings (an interconnected system of signals and track elements designed to ensure safe railroad operations) were identified in the track configuration planning process (see Table 10.5). Estimated signal costs for new interlockings were based on the average value for six new interlockings constructed on the nearby MBTA Fitchburg Main Line. Estimated costs to renew block signals were derived from the same source. Costs for interlocking renewal were estimated at two-thirds the cost of a new interlocking.

Table 10.5: New and Renewed Interlockings and Block Signals for Intercity 8 Option

Interlocking Location and Treatment	Installed Cost (2014$)	Quantity
Renew CPF-LO	$683,295	1
Renew Western Avenue	$683,295	1
New CPF-NC	$1,024,942	1
New CPN2 Crossover (B29)	$1,024,942	1
New CPN4	$1,024,942	1
Renew CPN6 So Nashua Station	$1,024,942	1
Renew CPN9	$683,295	1
Renew Nashua	$683,295	1
Renew CPN13 (12.86) Hills Ferry	$683,295	1
New CPN 18	$1,024,942	1
Renew CPN20	$683,295	1
New Manchester	$1,024,942	1
Renew CPN28 (Granite Street)	$1,024,942	1
New Concord	$1,024,942	1
Block Signals		
Renew 27/27.1	$147,872	1
Renew 30.6/30.7	$147,872	1
Renew 352/353 (So Nashua) MP7	$147,872	1
Renew 14.4/14.5 Mast Road	$147,872	1
Renew 16.0/16.1 Anheuser Busch	$147,872	1
Renew 500/499 (MP22)	$147,872	1
Renew 540/539 (West Mitchell Street)	$147,872	1
Renew 28.6 (Commercial Street)	$147,872	1

10.1.7 Automatic Highway Warning Devices (AHWD) Systems

The rail line has 35 highway and pedestrian crossings between Lowell and Concord. The Study team inspected each crossing with an accompanying PAR signalman to determine its condition and identify necessary signal and warning system upgrades for each crossing. The site survey ran south to north to view the conditions at each of the 35 crossings from Wotton Street in Chelmsford, Massachusetts to Hall Street in Bow, New Hampshire. Specific cities and towns visited and the number of active crossings include Chelmsford (3), Tyngsborough (2), Nashua (6), Merrimack (4), Manchester (14), Hooksett (2), and Bow (4).

The Study team's estimate includes all material and labor to purchase and install new equipment and remove and dispose of old equipment, including a five percent design contingency. The estimate includes costs for crossing houses complete with racks, crossing controllers, relays, and wiring necessary to control the wayside equipment. Constant warning time control equipment has been included in the estimate due to variation in speeds between passenger trains and freight trains that will both coexist on the line. Wayside equipment has been determined for each location to be either a two- or four-quadrant gate system or flasher-only system with foundations, cable, lights, and bells. A cost for a power service up-grade at each location has been included. All estimated backup details are based on 2014 dollars. This estimate does not include any costs for the operating contractor (force account), future

escalation, contractor's general conditions, overhead, profit, bond, or any other allowances. Other general information and assumptions used in developing this cost estimate follow:

1. Review of information contained in USDOT Crossing Inventory
2. Material and labor costs for contractor work are based on various sources, including estimating publications, historical contractor rates from similar project bids, estimators' experience, and a material list estimate from Safetran Systems dated 2004 as reference (material costs from that estimate were escalated to be consistent with recent cost information)
3. Assumption of manpower; assumes all work will be done on straight time
4. Does not include any credit for salvageable equipment
5. Does not include any cost for wayside signal system upgrades
6. Costs included for interface at locations where electric switch locks may be required
7. Cost was added at Crown Street and E. Hollis Street in Nashua between the main line and Hillsboro Branch line specifically for a crossing control interface between the two locations
8. From the site survey it was observed that the Manchester traffic signals along Canal Street provide signage and a steady flashing yellow light in advance of the crossing for warning motorists, so cost for an upgrade to this traffic system is not included
9. From the site survey it was observed that several locations have traffic signals within 200 feet of the Highway Rail Grade Crossing Warning System and will need to be interconnected to pre-empt the traffic signals in accordance with the Manual on Uniform Traffic Control Devices (MUTCD)

The resulting signal cost estimates for each crossing are enumerated in Table 10.6.

Table 10.6: Estimated Signal Costs for AHCW System Upgrades

City	State	Grade Crossing	MP	Cost (2014$)
Chelmsford	MA	Wotton Street	29.1	$241,750
Chelmsford	MA	Wellman Road	29.6	$260,650
Chelmsford	MA	Cross Street	30.0	$298,576
Tyngsborough	MA	New England Marine	30.5	$298,576
Tyngsborough	MA	Helena Drive/River Road	33.5	$258,203

Bow	NH	Robinson Ferry	68.3	$263,453
Bow	NH	Gavins Falls Road	69.8	$263,453
Bow	NH	Hall Street	71.0	$284,453
Segment Total				**$3,309,669**

10.1.8 Grade Crossing Track Renewals

Each of the highway grade crossings would also be renewed with new track and paving material. The estimated cost for upgrading each highway grade crossing was based on the average value to upgrade the track and crossing material for six substantial crossings on MBTA's ongoing Fitchburg Line Improvement Project at $165,950 per crossing.

10.1.9 Bridges

There are 25 railroad bridges along the route between Lowell and Concord spanning an aggregate 2,100 feet over waterways and roadways. The Study team obtained inspection reports, plans, and documentation for each bridge from PAR and MBTA. The Study team combined this information with selected field inspections to estimate costs to rehabilitate each railroad bridge along the route. The assessment of the bridge structures was limited to review and evaluation of this available information only. The scope of this Study does not include bridge inspection and/or development of an independent load capacity rating for any of the bridges. Available information used to asses and evaluate the 25 bridges within the Study limits includes the following:

1. Bridge Inspection Reports obtained from MBCR
2. Bridge Inspection Reports obtained from PAR
3. Bridge Rating Reports obtained from PAR
4. Bridge Plans obtained from PAR
5. Video and photos from a Hi-Rail trip along the rail corridor
6. Photographs of some bridges where access was possible
7. GIS mapping and online aerial photos of the bridges

A Bridge Summary Sheet was developed for each bridge to summarize the basic information and condition of each bridge as identified in available bridge inspection reports. Based on condition ratings, inspector notes, and available photographs, a recommended scope of repairs is presented, with concept-level cost item quantities identified. The recommended repairs are also given a weighted rating of "Minor," "Moderate," or "Extensive" based on a subjective evaluation of the available information. Unit costs for various repair/rehabilitation work items are utilized for each of the three weighted ratings, and the appropriate unit cost is then applied to the specific cost item quantity for the given bridge.

The condition of each bridge is summarized in Table 10.7. Bridge repair cost information was developed for the purpose of establishing order-of-magnitude capital investment levels and considered as representative of preliminary conceptual repair/rehabilitation requirements. As project design advances, development of more accurate needs and associated costs at each bridge based on further engineering assessment will be required, including hands-on inspections and load capacity ratings for two bridges that have not recently been rated.

Table 10.7: Estimated Bridge Rehabilitation Costs (2014$)

City/Town	Bridge No.	Length (Feet)	Bridge Structure	Deck Type	Spans	Costs
Lowell, MA	25.6	30' +/-	Deck Plate Girder	Open	1	$41,000
	25.7	154'-6"	Deck Plate Girder	Open	4	$99,000
	26.2	163'-0"	Thru Truss	Open	1	$183,000
Chelmsford, MA	28.6	43'-8"	Stone Arch	Ballast	2	$29,000
	29.1	13'-0"	I-Beam	Open	1	$58,000

10.1.10 Stations

Costs for station development were estimated for a number of alternative sites. Estimates relied on unit costs recently generated for MBTA's on-going improvements to the Fitchburg line. Those detailed capital costs were prepared by Jacobs Engineering and Keville Enterprises, Inc. in January 2013. The estimated Wachusett station construction cost with escalations and contingencies came to $13,303,000 for a station facility with a single track siding station with one 800-foot high-level side platform and 360 parking spaces.

Detailed costs for Wachusett were used to inform cost estimates for each of the proposed station sites through the use of allocation factors: variables such as the number of parking spaces, number of platforms, number of side tracks, square feet of existing wetlands, and the possibility of contaminated soil disposal. This enabled application of the Wachusett station unit costs even where site characteristics were different. The costs for a station at the Pheasant Lane Mall site include a parking garage estimated at 10 times the cost per space of a surface parking space. This figure is consistent with Jacobs' estimates for other parking garages.

10.1.11 Layover Facilities

Costs to develop layover yards for overnight storage and light maintenance of the service rolling stock were estimated for a number of alternative sites. Estimates relied on unit costs recently generated the MBTA's on-going improvements to the Fitchburg line. The estimated Wachusett layover construction cost with escalations and contingencies came to $13,303,000 for a layover facility with six tracks, including 9,655 track-feet available for the storage of trains.

These detailed costs were used to develop cost estimates for each of the proposed layover facilities through the use of allocation factors: variables such as the number of storage positions, total track length (feet), and the possibility of contaminated soil disposal. This enabled application of the Wachusett layover facility unit costs even where site characteristics were different.

10.1.12 Right-of-Way Improvements

Restoration of passenger service on the NHML will require some right-of-way improvements including relocation of fiber optic lines where new tracks are being restored to the right-of-way, vegetation removal, reestablishing ditches, and cleaning shoulder ballast. The right-of-way hosts three separate private fiber optic installations north from Lowell to Nashua, two between Nashua and Manchester and one from Manchester north to Concord. Based on the experience of Jacobs' telecommunications engineers, an allowance of $290,400 per route mile was used to estimate the costs of installing replacement fiber optic lines where new tracks were being laid. Allowances for other improvements were derived from earlier studies of the same right-of-way with costs escalated to 2014 dollars and are listed in Table 10.8.

Table 10.8: Allowances for Right-of-Way Improvements

Right-of-Way Improvement	Unit	Unit Cost (2014$)
Relocate fiber optic lines	Route Mile	$290,400
Vegetation management	Route Mile	$20,925
Reestablish ditches	Route Mile	$39,600
Shoulder ballast cleaning	Track Mile	$39,930

10.1.13 Positive Train Control

The Rail Safety Improvement Act of 2008 (RSIA) created a new infrastructure requirement for all U.S. passenger railroads. This new requirement should reduce the likelihood of the following:

- Train-to-train collisions
- Injuries to rail roadway workers
- Over-speed derailments
- Accidents due to misaligned switches to sidings

Under the RSIA, all conventional passenger railroads must operate with PTC as soon as possible after December 2015. The MBTA installation of PTC is lagging the 2015 deadline like most of its peers and its

ultimate costs are unknown. The Study team employed a 2009 economic analysis prepared by the FRA[30] to account for PTC cost, and then escalated the estimates to 2014 dollars at four percent per annum.

At the most basic level, all PTC systems require three equipment elements:

- Wayside Devices: Equipment to detect, monitor, and communicate the status of track and switches installed in the field
- Locomotive/Cab Car Devices: Equipment to monitor and control train status relative to information on field conditions communicated from central control and wayside equipment
- Central Office Equipment: To integrate and communicate information concerning the status of trains, track maintenance crews, switches, signals, and tracks

The relevant work to install onboard locomotive and cab car devices should be completed for MBTA, PAR, and Amtrak fleets well before the proposed passenger rail service north of Lowell would be implemented. Similarly PAR and MBTA dispatching offices should have the relevant Central Office Equipment by that time. Any new passenger railway mileage will require the installation of wayside devices.

Using information from the above referenced FRA study, the Study team conservatively estimated that the more expensive Advanced Civil Speed Enforcement System (ACSES) wayside equipment would be deployed on the route with an average cost of $147,215 per track mile. If Enhanced Traffic Management System (ETMS) is installed, the PTC costs may be lower than estimated here.

10.1.14 Railroad Appliances

Various appliances such as train defect detectors, rail lubricators, and electric locks for hand-thrown turnouts would be required on the refurbished line. Installed unit costs for these appliances and estimated quantities required are listed in Table 10.9.

Table 10.9: Unit Costs and Quantities of Railroad Appliances for Intercity 8

Railroad Appliance	Installed Cost (2014$)	Quantity
Train Defect Detector	$45,000	1
Rail Lubricator Unit	$8,000	6
Electric Locks for Industrial Sidings	$75,000	5
Electric Locks for Customer Turnouts	$75,000	12

10.2 Non-Infrastructure Costs

[30] Roskind, Frank D, Senior Industry Economist, Federal Railroad Administration, Office of Safety Analysis POSITIVE TRAIN CONTROL SYSTEMS: ECONOMIC ANALYSIS. DEPARTMENT OF TRANSPORTATION, FEDERAL RAILROAD ADMINISTRATION, 49 CFR PARTS 229, 234, 235, AND 236 [DOCKET NO. FRA-2006-0132, NOTICE NO. 1] RIN 2130-AC03 July 10, 2009 202 302 9704 pp 112-119 (Retrieved from http://www.fra.dot.gov/downloads/PTC_/RIA_/Final.pdf on July 21, 2009)

10.2.1 Multipliers for Allowances

As per typical practice, costs for various professional services and incidental non-itemized expenditures are estimated on the basis of total costs for all rail infrastructure improvements. These multipliers for professional services and incidental work are listed in Table 10.10.

Table 10.10: Professional Services and Incidental Items

Culverts and retaining walls	3% of infrastructure cost
Environmental (soil disposal, noise abatement, LEED*)	3% of infrastructure cost
Final engineering design	8% of infrastructure cost
Construction phase engineering services	4% of infrastructure cost
*LEED – Leadership in Energy and Environmental Design	

10.2.2 Railroad Services

Mechanisms for estimating the costs for railroad project management, inspections, and protective flagging are shown in Table 10.11.

Table 10.11: Railroad Services and Estimated Costs (2014$) of Inspections and Flagging for Intercity 8

	Unit Cost	Quantity
Railroad Project Management	3% of Infrastructure cost	N/A
Maintenance & Protection of Railroad (Inspections)	$2.00/day	270
Flagging	$2.00/day	540

10.2.3 Land

Beyond the railroad right-of-way that will be shared with PAR freight trains, land will be required for stations, parking, and overnight train storage yards. The cost for this land was estimated by consulting local public assessor records in Tyngsborough, Nashua, Bedford, Manchester, and Concord to determine the current assessed value of each parcel identified for a potential station or layover yard. Where only a portion of the parcel would be required for the rail facility, GIS tools were used to determine what fraction of the overall parcel would be necessary and to prorate the cost accordingly.

Acquisition of private land for transportation improvements can be a litigious process. An allowance of 220 percent was added to all raw land costs to allow for negotiations, takings, eminent domain, and legal costs. The 220 percent was derived from the Study team's experience working on similar projects in other jurisdictions; New Hampshire's experience may be different. Table 10.12 shows the assessed land values and estimated costs for selected station and layover sites.

Table 10.12: Assessed Land Value and Estimated Cost (2014$) for Selected Station and Layover Sites or Intercity 8

Facility Type	Parcel Size (Acres)	Required Portion	Assessed Value per Acre	Estimated Value	Estimated Cost with 220% Assemblage Factor
Stations					
Nashua Crown Street	6.826	1.0	$ 45,224	$308,700	$987,840
Bedford/MHT	6.000	0.33	$ 29,416.67	$444,400	$1,422,080
Manchester Granite Street	0.5544	1.0	$ 279,132.58	$148,800	$476,160
Concord Stickney Avenue	6.08	1.0	$ 237,990	$1,447,000	$4,630,400
Layover Yards					
Concord Stickney Avenue	6.08	1.0	$ 237,990	$1,447,000	$4,630,400

10.2.4 Infrastructure Contingency

In accordance with federal recommendations, a 35 percent contingency was applied to the sum of all infrastructure, engineering, and land costs described above to allow for unforeseen and unusual circumstances that might have been unaccounted for in this conceptual engineering cost estimate.

10.2.5 Rolling Stock

For Intercity 8, the Amtrak *Downeaster's* standard consist of four coaches with a locomotive used as a model (see Table 10.13). It was further assumed that the Intercity 8 service would operate in the same equipment pool with the *Downeaster's* five train sets adding one more four-car train set, one spare coach, and one spare locomotive to Amtrak's North Station complement.

Table 10.13: Unit Costs (2014$) and Quantities of Railroad Rolling Stock for Intercity 8

Rolling Stock	Purchase Price	Quantity
Coaches	$2,530,000	5
Locomotives	$5,320,000	2

10.2.6 Trackage Rights

The proposed rail services would be operated on a mix of tracks owned by MBTA in Massachusetts and by successors to B&M in New Hampshire. MBTA recently transferred $35 million dollars to PAR in exchange for the right to offer commuter rail service on B&M/PAR tracks approximately 37 miles north from Tyngsborough, Massachusetts to Concord, New Hampshire. The value of these rights to MBTA and PAR is approximately $946,000 per route mile. Without this transaction, MBTA and NHDOT would need to purchase trackage rights from PAR to operate into New Hampshire. Consequently one of the cost elements for the commuter rail options is the $946,000 per route mile one-time trackage fee for every route mile operated into New Hampshire.

Intercity routes operated by Amtrak, in contrast to MBTA, have statutory rights to operate over every railroad in the nation without paying trackage fees. Consequently, the trackage rights and resulting fees would not be a concern or a cost for the Intercity 8 service option.

10.3 Total Estimated Costs

The Intercity 8 service option is projected to cost $172.7 million for infrastructure and land, plus a $60.5 million contingency allowance and $23.3 million for the purchase of rolling stock that would be NHDOT's responsibility – for a total of $256.5 million. These costs are 2014 dollars. See Table 10.14 for a summary.

Table 10.14: Summary of Projected Capital Costs (2014$) for Intercity 8

Main Line Tracks	$42.1
Track Switches	$7.8
Interlockings	$12.0
Block Signals	$1.2
Grade Crossing Signals	$8.3
Grade Crossing Track Renewals	$5.6
Bridges	$15.4
Stations	$18.7
Layovers	$4.8
Right-of-way Improvements	$8.8
Positive Train Control	$9.5
Railroad Appliances	$1.0
Direct Construction Expense Subtotal	**$135.2**
Multipliers for Allowances	$24.3
Railroad Services	$5.7
Land for Stations	$0.9
Land for Layovers	$1.4
Assemblage Allowance (220%)	$5.2
Subtotal Land	**$7.5**
Contingency	$60.5
Grand Total (infrastructure)	**$233.2**
Coaches	$12.7
Locomotives	$10.6
Grand Total (rolling stock)	**$23.3**
Trackage Rights	**$0.0**
Total Project Value	**$256.5**

11 Forecast Operating Costs and Revenues

11.1 O&M Costs

Operations & Maintenance (O&M) costs are expenses necessary for operating the railway service:

- **Transportation:** Train crews, fuel, dispatching, train supplies, revenue collection, station staffing (if any), and transport supervision
- **Maintenance-of-Equipment (MoE):** Sometimes referred to as "Mechanical," includes the maintenance and cleaning of locomotives and coaches
- **Maintenance-of-Way (MoW):** Sometimes called "Engineering," includes maintenance of track, signals, communications, right-of-way, bridges, stations, and other facilities
- **Administration:** General management, marketing, human resources, accounting, material management, and other similar support functions

Two stages of O&M cost estimates were prepared for the Study:

1. A set of preliminary estimates for the three intercity rail, six commuter rail, and three bus options
2. Refined final estimates for the preferred Intercity 8, two commuter rail, and three bus options

11.1.1 Preliminary Estimates of O&M Cost

The Study team's approach for estimating O&M costs were different for the intercity rail, commuter rail, commuter bus and feeder bus service components. The intercity rail estimates are described below.

Service and operations planning for each intercity rail option was developed to include estimates of daily train miles, rolling stock requirements, track miles required, number and location of stations, and service schedules. The three preliminary options were reviewed with Amtrak staff assigned to advise the Study team and revised to reflect their feedback. The Study team also consulted with Amtrak for guidance on preparing preliminary estimates of operating costs for the SDP. The team was referred to documentation from several SDPs:

- *Feasibility Report on Proposed Amtrak Service: Chicago-Rockford-Galena-Dubuque*; prepared by M.W. Franke, Sr. Director – Corridor Planning and R.P. Hoffman Principal Officer – Midwest Corridors, Amtrak, Chicago, Illinois; revised June 22, 2007
- *Feasibility Report on Proposed Amtrak Service: Quad Cities-Chicago*; prepared by M.W. Franke Assistant Vice President – State and Commuter Partnerships (Central), R. P. Hoffman Principal Officer – Midwest Corridors and B.E. Hillblom Senior Director – State Partnerships; Amtrak Chicago, Illinois; January 7, 2008
- *Feasibility Report of Proposed Amtrak Service: Chicago – Peoria*; prepared by Policy and Development Department (Central) Amtrak, Chicago, Illinois; September 26, 2011
- *New York-Vermont Bi-State Intercity Passenger Rail Study: Identification and Evaluation of Alternatives*; March 9, 2012

Review of these documents revealed that the preliminary (and final) operating cost estimates for SDPs are typically derived in two ways: a measure of annual train miles is often the only cost factor used to derive a very simple and transparent operating cost estimate while other studies rely on Amtrak staff to develop estimates. The Study team elected to use the annual train mile approach, as documentation concerning Amtrak's methodology is not publicly available. The cost-per-train-mile figures from the referenced reports ranged from $29.78 to $33.08 in the Amtrak Chicago-Quad Cities Report (Table 11.1) to $66.01 in the Amtrak Ethan Allen Report (Table 11.2).

Table 11.1: Amtrak Chicago-Quad Cities Operating Cost Calculations (2007$)

	Route A UP* Belvidere	Route B ICE* Airport	Route C CN* Direct	Route D ICE-CN* Hybrid
Length of Route (miles)	184.0	188.6	182.2	181.0
No. of Rail Carriers	4	5	2	4
Proposed Scheduled Running Time (hours:minutes)	5:25	5:42	5:10	5:22
"Order of Magnitude" Capital Cost (In Millions)	$43.8	$48.9-$55.4	$32.3	$34.5
Estimated Annual Ridership	53, 600	44, 300	74, 500	58, 400
Estimated Annual Revenue (In Millions)	$1.1	$1.0	$1.5	$1.2
Estimated Annual Operation Expense (In Millions)	$4.1	$4.1	$4.4	$4.2
Estimated Annual Operation Contract (In Millions)	$3.0	$3.1	$2.9	$3.0
Train Hours	5.4	5.7	5.2	5.4
Annual Ridership				
Annual Train Miles	134,320	137,678	133,006	132,130
Annual Train Hours	3,954	4,161	3,772	3,918
Cost-per-Train Mile	$30.52	$29.78	$33.08	$31.79
Cost-per-Train Hour	$1,036.88	$985.34	$1,166.59	$1,072.07

Table 11.2: Amtrak Ethan Allen Operating Cost Calculation (2012$)

Fully Allocated Unit Operating Cost" per Train Mile	$66.01

Source: New York – Vermont Bi-State Intercity Passenger Rail Study Identification and Evaluation of Alternatives – Phase One; March 9, 2012

Amtrak reviewed these findings and agreed that the average costs per train mile published for the Amtrak *Downeaster* service would be used to estimate operating costs for Capitol Corridor intercity rail options. The use of the *Downeaster* service between Portland, Maine and Boston, Massachusetts is especially appropriate since this service also operates on tracks owned by MBTA and PAR and runs into Boston's North Station. Table 11.3 summarizes the cost factors that contribute to that service's $36.02 cost-per-train mile figure. This metric is roughly equivalent to the costs applied for Midwestern and New York/Vermont services reviewed in the studies recommended by Amtrak. Using the simple cost of $36 per train mile, the preliminary estimates of operating cost in Table 11.4 were derived for the three intercity service options.

Table 11.3: Preliminary *Downeaster* Operating Cost Calculation (2012$)

Annual Budget	$15,000,000
One Way Trip Length	114
Trips per Day	10
Trips per Year	3,652.5
Annual Train Miles	416,385
Cost per Train Mile	$36.02

Source: Northern New England Passenger Rail Authority (NNEPRA) 2012

Table 11.4: Derivation of Preliminary Estimates of Intercity Rail Operating Costs

Intercity Service Option	Trips per Day	Train Miles per Day	Train Miles per Year	Annual Operating Cost (@ $36/train mile)	Preliminary Estimate of Annual Operating Cost (In Millions, 2012$)
Intercity 8	8	586	214,036	$7,705,296	$7.7
Intercity 12	12	880	321,054	$11,557,944	$12
Intercity 18	18	1,319	481,581	$17,336,916	$17

11.1.2 Final Estimates of O&M Costs

O&M costs evolved over the Study's preliminary stages and then were updated at the project close to reflect newer, but not substantially different information concerning operating costs for the *Downeaster* service used as a cost model for this service. An updated O&M cost estimate is discussed below.

The intercity rail service options that advanced through preliminary screening were developed to a higher level of detail, including estimates of daily train miles, rolling stock requirements, track miles required, number and location of stations, and service schedules.

Revenue forecasts were then prepared so that the required operating support could be identified. Table 11.5 contains final estimates of boardings and passenger miles for Intercity 8 and identifies new transit trips that would be attracted to the service.

Table 11.5: Final Estimates of Demand and Passenger Miles for Intercity 8

	Boardings	Miles to Boston	Passenger Miles
Concord	78	73.3	11,497
Manchester	186	55.5	20,758
Bedford/MHT	77	50.1	7,715
Nashua	132	38.8	10,217
New NH Boardings	473		
Annual Boardings (In Millions)	2.78		
Annual NH Project Boardings (In Millions)	0.24		
Incremental Daily Passenger Miles			48,853
Annual Passenger Miles (In Millions)			17.8

11.2 Estimated Passenger Revenues

Two rounds of revenue forecasts were prepared for the Study. Preliminary forecasts were used to screen the options down to an intermediate and then final set of multi-modal transportation investment options, including the preferred Intercity 8 option. The final revenue forecast was based on the Intercity 8 final ridership forecast.

11.2.1 Preliminary Estimates of Passenger Revenue

Preliminary estimates of passenger revenue were based on the ridership forecasts described in *Section 7: Market Analysis*. For screening purposes, the service was assumed to use a fare structure similar to MBTA's commuter rail fares and that daily ridership would be converted to an annual estimate using a factor of 284.4 based on MBTA experience. The use of a commuter rail annualization factor was considered prudent since the forecast model used for preliminary estimates was a commuter rail model. The resulting preliminary forecasts of annual revenue are shown in Table 11.6.

Table 11.6: Preliminary Forecasts of Intercity Ridership and Revenue

Intercity Rail Station	One Way Fare	Average Revenue per Passenger	Forecast SB Boardings			Annual Revenue (In Millions, 2012$)		
			Intercity 8	Intercity 12	Intercity 18	Intercity 8	Intercity 12	Intercity 18
Concord	$12.00	$11.26	60	70	90	$0.4	$0.4	$0.6
Manchester	$11.00	$10.01	130	160	190	$0.7	$0.9	$1.1
Bedford/MHT	$11.00	$10.01	120	140	160	$0.7	$0.8	$0.9
Nashua	$10.00	$9.41	320	370	440	$1.7	$2.0	$2.4
Totals			630	740	880	$3.5	$4.1	$4.9
Revenue per Passenger Mile						$0.21	$0.20	$0.20

11.2.2 Final Estimates of Passenger Revenue

The final estimate of passenger revenue for the Intercity 8 option (Table 11.7) was based on the *Downeaster* ridership model forecasts prepared by Amtrak and the *Downeaster's* average revenue per passenger mile of $0.173. Since the Amtrak model generated annual ridership estimates, it was unnecessary to apply an annualization factor.

Table 11.7: Final Forecasts of Intercity 8 Ridership and Revenue for Eight-Train-per-Day Service

	Miles to Boston	Typical Daily Boardings	Annual Boardings	Annual Passenger Miles	Annual Revenue (In Millions, 2014$)
Concord	73.3	78	28,350	4,156,110	$0.7
Manchester	55.5	186	67,800	7,552,920	$1.3
Bedford/MHT	50.1	77	28,150	2,820,630	$0.5
Nashua	38.8	132	48,350	3,771,300	$0.7
Totals		473	172,650	18,300,960	$3.2

11.3 Estimated Operating Cost Performance

Table 11.8 lists performance metrics for Intercity 8 that can be used to compare its productivity and required operating support against the other Study options. Intercity 8 is forecast to require $4.5 million of annual operating support beyond proceeds from passenger revenues.

Table 11.8: Final Intercity 8 Service Option Performance Metrics

Performance Metric	Cost (*$)
Operating Cost per New Transit Passenger Trip	$31.91
Operating Cost per New Transit Passenger Mile	$0.43
Revenue per New Transit Passenger Mile	$0.173
Operating Deficit (In Millions)	$4.53
Operating Deficit per New Transit Passenger Trip	$18.78
Operating Deficit per New Transit Passenger Mile	$0.25
Required Operating Support (In Millions)	$4.5

**Note: Operating costs are based on unit costs in 2012$. Ridership and fare rates are current to 2014. Therefore, estimates of operating deficit and required support may vary when operating unit costs become available for 2014$.*

12 Preferred Intercity Rail Public Benefits

This section reviews quantifiable public benefits that would be derived from the construction and operation of the Intercity 8 service in the Capitol Corridor:

- Reduced VMT on parallel highways leading to reduced congestion and improved air quality
- Station area benefits stimulating and supporting sustainable land use patterns
- Economic development benefits resulting from rail service construction and operation
- Positive equity impacts on low income and minority populations in New Hampshire
- Freight service benefits

12.1.1 VMT

Public transportation investments generally have some impact in reducing automobile traffic in the corridors where they operate. Reduced automobile traffic in turn tends to have a positive impact on air quality and roadway congestion. As estimated in *Section 7: Market Analysis*, the preferred Intercity 8 service option would reduce daily vehicle miles on the corridor's limited access highways by 44,794.

12.1.2 Station Area Benefits and Recommendations

Restoration of intercity passenger rail service between Concord and Boston along the NHML is expected to result in positive benefits that will stimulate and support new development. Ideally this would lead to sustainable development in the dense downtown cores of Concord, Manchester, and Nashua and help encourage sustainable development in the vicinity of the proposed airport station.

The Study carefully considered existing development and zoning in each proposed station area to reach the findings and recommendations summarized below.

All three cities within the New Hampshire Study area have, to varying degrees, existing transit-supportive zoning and land use plans and policies. Some potential station locations would be better suited for TOD and supporting growth in transit use than others. Station locations in the urban centers of Concord, Manchester, and Nashua are all primed for future transit growth and TOD.

Following are recommendations to build on existing transit-supportive zoning and land use plans and policies:

Concord

- Continue to implement the Opportunity Corridor Performance (OCP) district plan; this plan has many of the elements necessary to promote a transit-supportive environment
- Create policies to limit parking and consider charging a higher rate; consider updating the zoning code to allow for parking maximum requirements instead of parking minimums for new development; parking supply can require less land if managed in parking structures, as opposed to surface lots
- Allow for the greater residential and commercial densities and zoning incentives for increased development in station area
- Define maximum setbacks to encourage higher density development; consider removing minimum setbacks
- 150-foot minimum lot frontages are too large to allow for the diverse mix of uses that the OCP district permits; a smaller frontage, such as the 22-foot minimum allowed in the Central Business District (CBD), would create a more walkable and pedestrian friendly environment
- Update the floor area ratio to at least one, to promote more density in the OCP district

Manchester

- Implement recommendations in the Master Plan to update the zoning ordinance to allow for mixed use and high-density residential properties
- Allow multi-family and elderly housing as a permitted use instead of as a conditional use
- Define specific parking maximums to allow for consistent development and ensure parking supply does not exceed demand; consider charging a higher rate for parking
- Allow for residential and commercial densities – zoning incentives for increased development in the station area
- Dimensional regulations are not defined for the CBD, the zoning immediately around the station, other than a floor area ratio of five
- The city should further define the maximum setbacks and other dimensional regulations to ensure that the urban design of new development enhances walkability of the area

Bedford/Manchester Airport

- The proposed station area lacks strong existing mixed-use or TOD zoning
- The Town of Bedford has prepared plans and policies that support the development of a mixed use transit hub at the proposed station location, but no progress has been made towards achieving this vision.
- The potential station would primarily be used by residents who live in south suburban Manchester and for passengers traveling to and from the airport
- This station would likely function as a park-and-ride location, with less of a focus on TOD
- The area could potentially benefit from more commercial development, serving the needs of passengers traveling to and from the airport

Nashua

The area surrounding the proposed station is currently zoned General Industrial. The potential station could benefit from a zoning change to allow for more development, such as commercial and/or mixed use. Former industrial spaces could also be redeveloped into commercial properties. Commercial uses could lead to more jobs near the transit station, making this a strong location in terms of FTA criteria. Mixing uses would add residential development opportunities, thereby increasing the population that lives within a half-mile of the proposed Crown Street station.

- The allowed uses by zoning are not optimal for encouraging TOD and a more walkable and urban environment
- Specific urban design principles should be created, such as small or no minimum setbacks and narrow lot frontages to encourage higher-density development
- The existing City of Nashua TOD land use code would be appropriate to apply to this location
- Recommend policies to limit parking and potentially charge for parking
- Consider updating the zoning code to allow for parking maximum requirements instead of parking minimums for new development
- Consider working with residential developers to unbundle parking from the residential unit

12.1.3 Economic Benefits

Building upon the land use and economic development analyses, the Study team prepared an economic development assessment aimed at capturing the potential economic benefits of the corridor alternatives. The Study team's analysis focused on the final alternatives, including intercity passenger rail to Concord and commuter rail to Nashua or Manchester. It also considered improvements to the

existing commuter bus network. The SDP only reports findings for the preferred Intercity 8 option compared to the No Build alternative.[31]

Economic Benefits of Transportation Investments

The Study team examined the literature and findings from recent studies of similar regional public transportation enhancement projects. Numerous studies have identified a net positive benefit of transport investment to the regional economy, resulting in travel time savings and congestion reduction, expanded access to jobs and the workforce, and new development attracted to station areas. Studies have also found a positive impact on property values within station areas. While only a few studies have specifically examined intercity passenger rail, evidence from other rail system expansions in the greater Boston region similarly suggests that transit investment will have a positive effect on the communities it serves.

Station Area Economic Development Benefits

The Study team conducted interviews with local stakeholders to gather information on the impact that the various proposed services could have in encouraging new development over the next 20 years. There was general consensus that passenger rail service (intercity or commuter) to Boston is important for southern New Hampshire's future development. While some high-tech, residential, and institutional development is currently occurring near several proposed station locations, respondents felt that this would be difficult to maintain or boost (particularly in the case of high-tech) without expanded passenger rail service. It was widely expressed that these sorts of transportation enhancements can help to attract the type of workers necessary to facilitate growth, namely a younger demographic looking for urban to semi-urban living with walkable amenities.

The Study team also assembled data on land use and zoning to evaluate the potential impact of the various project alternatives on development and redevelopment. The Study team estimates were measured in terms of commercial square footage (office and retail) and housing units. Table 12.1 shows that the eight trains per day serving Nashua, Manchester, and Concord in the Intercity 8 option could potentially encourage development of approximately 2,200 new residential units and 1.3 million square feet of commercial space supporting 3,700 new jobs by the year 2030.

Table 12.1: Total Development Potential for Intercity 8

Commercial (Square Feet)	Residential (Units)	Jobs
1,284,000	2,200	3,700

[31] For more information on economic development impacts, see Appendix 7 to the Capitol Corridor AA Final Report (Task 7 Detailed Evaluation of Alternatives)

Regional Economic Benefits

The economic modeling tool IMPLAN was used to estimate the economic benefits to the southern New Hampshire region of each intercity and commuter rail alternative. The following economic benefits were evaluated:

- Short-term benefits as a result of spending on construction of rail improvements in New Hampshire
- Long-term benefits as a result of the attraction of more residents and jobs to southern New Hampshire; these include benefits from construction of new real estate, as well as ongoing benefits from new worker earnings reinvested in the local economy

Time-savings benefits to travelers cannot be directly monetized in this type of economic analysis. However, they are capitalized into land values, and, therefore, are indirectly considered through the real estate effects. Benefits of bus alternatives were not estimated, as they would involve minimal capital investment, and stakeholder interviews suggested that associated development impacts would also be minimal.

The economic modeling found that the preferred Intercity 8 option would generate the greatest construction impacts of all the final alternatives (intercity rail, commuter rail, bus) under consideration (see Table 12.2). It would, however, have less development-related benefits when compared to the Manchester Regional Commuter Rail option due its lower service frequency. Overall, Intercity 8 has the potential to generate 350 new jobs over the construction period (2019-2022), 2,460 jobs related to new real estate development between 2021 and 2030, and 1,140 new jobs annually in 2030 and beyond (with benefits beginning to accrue after 2021) due to reinvested worker earnings. Table 12.3 shows this new real estate development is projected to add $750 million to the state's output between 2021 and 2030, with reinvested earnings adding $140 million per year beyond 2030.

Table 12.2: Employment Impacts of Intercity 8 (Number of Jobs)

Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
350	2,460	1,140

Table 12.3: Forecast Gross Regional Product Impact of Intercity 8 (In Millions, 2014$)

Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
$100	$750	$140

12.1.4 Equity Impacts[32]

Equitable access to transportation services – and the mobility benefits that these services confer on riders – is an important consideration when assessing the alternatives developed in the Study. Any major new public transportation (intercity rail, commuter rail, or express bus) service would support broad improvements in mobility. They are also a particularly critical tool in increasing the mobility of transit-reliant or -dependent populations, generally including households below the poverty line, minorities, and households in affordable housing units. U.S. Census data was used to calculate statistics related to income, race, and housing for households and individuals in Census tracts within a half-mile of the various Capitol Corridor alternatives:

- PAR right-of-way between the state lines of New Hampshire and Massachusetts and the proposed rail station locations en route to Concord
- BX bus route between the state lines of New Hampshire and Massachusetts and the existing Manchester, New Hampshire BX station
- Concord Coach bus route between the state lines of New Hampshire and Massachusetts and the existing Concord, New Hampshire Concord Coach station

These data were also collected for the states of New Hampshire and Massachusetts and the U.S. as a whole. Comparison between the alternatives within the larger geographic context supported the analysis of which alternatives minimize potential adverse impacts on concentrations of households below the poverty line, minority populations, and households in affordable housing units, while supporting equitable transit access by these populations.

It is notable that no cuts to intercity or express bus services are contemplated should the Intercity 8 service be implemented. The overall scope of transport services would actually be increased under this scenario. It is likely that the collocation of the bus and rail terminals in Concord and Manchester would strengthen both the bus and rail services as it has at the *Downeaster's* joint bus/rail terminal in Portland, Maine.

Table 12.4 summarizes findings of the Intercity 8 equity analysis compared with the status quo of continued express and intercity bus services. The Intercity 8 option would offer service to the following concentrations:

- Households below the poverty line
- Minority populations
- Households living in affordable housing units

[32]For more information on economic development impacts see Appendix 7 to the Capitol Corridor AA Final Report (Task 7 Detailed Evaluation of Alternatives)

This option would also expand access to new transportation alternatives in downtown Nashua, Manchester, and Concord, which have among the state's largest concentrations of transit-reliant or -dependent persons and households.

Table 12.4: Equity Comparison of Intercity Rail and Base Service

Station	Rail	Express Bus	Average Median Income	Pop Below Poverty Line	Minority Pop	Affordable Housing Units	Base Services	Intercity 8 Rail
Concord, NH	X	X	$39,000	18.0%	9.7%	398	X	X
Manchester, NH	X	X	$30,300	29.5%	26.1%	675	X	X
Bedford/MHT	X		$65,500	4.5%	5.2%	0		X
N. Londonderry, NH		X	$82,900	1.7%	4.7%	minimal	X	
Londonderry, NH		X	$84,700	3.9%	5.2%	minimal	X	
Nashua, NH		X	$80,500	4.4%	12.9%	minimal	X	
Nashua, NH: Crown St	X		$52,500	14.9%	12.2%	28		X
Salem, NH		X	$75,300	3.7%	5.9%	minimal	X	

Sources: U.S. Census, American Community Survey 2008-2012; various local New Hampshire Housing Authorities

The three populations considered as part of this equity analysis – population below the poverty line, minority populations, and households living in affordable housing units – tend to be concentrated in the central areas of Concord, Manchester, and Nashua. When compared against the existing commuter bus services, Intercity 8 would offer comparatively higher levels of service and transit access to these populations with minimal adverse impacts anticipated. The equity of and access to the rail alternatives would improve as transit service extends north to Concord. Intercity 8 would reach more individuals and households living below the poverty line, minority households, and households living in affordable housing units. The existing commuter bus service (or improved bus services) would also not adversely impact these populations, but it would not offer expanded access to these populations through new station locations.

12.1.5 Freight Service Benefits

As noted in the discussion of existing services in Section 5, the NHML carries most of the state's inbound rail freight, receiving three quarters of all rail freight tonnage shipped into New Hampshire. While the freight received is quite diverse, traffic flow is dominated by coal for electric generation shipped to Bow, New Hampshire. Clay, concrete, glass, and stone also comprise much of the remaining rail freight tonnage moving on the corridor. Other freight shipped along the corridor includes farm products, lumber and wood products, food, chemicals, and some nonmetallic minerals. Significantly more freight rail traffic is shipped into southern New Hampshire than is shipped out. Shippers categorize the small amount of outbound freight rail traffic as miscellaneous freight.

Most rail traffic currently shipped to New Hampshire is for local consumption and the volume of outbound rail traffic other than building materials (predominately sand and gravel) is quite minor.

Unless there is major shift New Hampshire's economy to produce, process, or consume large volumes of bulk commodities, it is unlikely that the total volume of rail traffic to or from the Granite State will grow at a rate that varies significantly from expected population growth. That is not to say that rail freight in the state would not benefit from improvements to a key rail line serving the state's major population centers. This portion of the SDP briefly discusses how investment in intercity passenger rail service might benefit freight services and commodity shippers along the NHML.

The largest rail shipper on the NHML (and the largest in the state) is PSNH Merrimack Generating Station. Merrimack Station is PSNH's largest power plant constituting approximately 10 percent of the state's power generation capacity. At 496 megawatts it produces enough energy to supply 190,000 New Hampshire households, and employs about 100 people. Its two coal-fired units were built in the 1960s and were once the cheapest source of electricity for the state.

But in recent years, New England has been become increasingly tied to natural gas. In 2013, natural gas powered plants produced 46 percent of the region's power, up from 15 percent in 2000. At this time, natural gas is cheaper than all other forms of energy. Further growth in the use of natural gas, however, is limited by pipeline capacity to supply the region. Until deficiencies in the capacity of the regional gas supply network are addressed, it is likely that Merrimack Station will continue to receive eight to 10 unit trains of coal each month using the NHML. However, in the long run, it seems likely that the gas network bottleneck will be addressed. At that time, the economic attractiveness of Merrimack Station might be reduced and eventually close. When, and if, it does close, the economic sustainability of this 45-mile branch will be jeopardized.

PSNH is not the only rail shipper on the NHML. The Nashua Corporation in Nashua, Anheuser-Busch and Jones Chemical in Merrimack, and Nylon Corporation of America in Manchester are among the more-prominent of perhaps a score of firms that ship or receive rail freight via the NHML. Should PSNH close its operations, the economic attractiveness of rail shipping for these smaller firms could be substantially degraded as the fixed cost of maintaining the line is spread over fewer tons of freight. These enterprises and their contribution to the regional economy could be in peril.

The operation of intercity passenger (or commuter) rail on the line would provide one more user for the line that would defray some of the shared costs for its upkeep and operation. With a passenger rail service on the line, the cost of providing existing freight service would be somewhat reduced, potentially improving conditions for PSNH to keep operating its plant at Bow. No tangible estimate of this impact has been produced, but the positive influence of the passenger rail service on the economic operation of the 45-mile freight branch seems clear.

To facilitate shared operation of the line by freight and passenger services, the infrastructure improvements were designed to minimize the potential for conflicts between passenger and freight trains. The track configuration would offer two main lines through Nashua and Manchester Yards. Industrial sidings would be established to allow local trains to service Nashua Corporation and the Anheuser-Busch brewery without blocking the main line. The Merrimack Running Track would be

restored to provide similar capacity for joint use by freight and passenger trains in this section and a new receiving track would be built at the PSNH facility to keep coal trains from standing on the main line.

Sidings are at locations where local land use plans encourage industrial growth and development. Therefore, the investment in passenger rail service that encourages TOD may also encourage rail freight use by enhancing the capacity for freight operations in areas designated for heavy industry and facilitating the creation of "freight villages."

12.1.6 Conclusion

The proposed intercity rail service would have demonstrable positive impacts in several areas. The following public benefits would be expected with the implementation of improved intercity or commuter rail service in the corridor:

- Reduced VMT on parallel highways, leading to reduced congestion and improved air quality
- Support for sustainable development patterns and uses within station areas
- Economic development in the form of jobs, commercial development, and home construction
- Positive mobility impacts on low income and minority populations in New Hampshire
- Sustaining current industrial development in southern New Hampshire and supporting possible future growth in heavy industry

13 Preferred Intercity Rail Implementation and Finance

13.1 Implementation

The New Hampshire Capitol Corridor project was initiated to inform New Hampshire officials and interested stakeholders of the costs, benefits, requirements, and obligations associated with substantially expanding non-automotive passenger transportation services in the Route 3 corridor encompassing Nashua, Manchester, and Concord and linking them with Boston. The range of alternatives considered in the overall joint FRA/FTA project included intercity passenger rail service, extensions of existing MBTA commuter rail service, and enhancements to the existing express bus network that serves south central New Hampshire.

As the Study is complete, New Hampshire officials have made no decisions regarding which public transportation enhancement, if any, they are prepared to support and pursue at this time.

Should New Hampshire officials decide that they are interested in developing an intercity rail service, the Study and this SDP provides a "blueprint" for service design, infrastructure investment, likely ridership, revenues, and costs. The Study also provides full NEPA documentation. This collection of analyses together with the NEPA documentation poises the Intercity 8 project for implementation, provided that New Hampshire officials and the FRA identify a mutually attractive mechanism for project financing.

Should New Hampshire elect to develop the Intercity 8 eight-train-per-day intercity passenger rail service, they would need to notify Amtrak, PAR, and MBTA of their intention to develop and operate the service. It has been presumed that Amtrak would be the operator, but under some of the most recent federal passenger rail legislation it is possible that MBTA, PAR, or a third party could operate the service. Depending upon the selected operator, details concerning how PAR would be engaged in service operation would need to be identified and resolved. Under Amtrak operation, the model for PAR/Amtrak cooperation is found in the parallel *Downeaster* Corridor. Should MBTA be asked to operate the service, it already owns passenger rail trackage rights to Concord. The model for MBTA operation would include elements of its Pilgrim Partnership Agreement with Rhode Island and elements of its new seasonal Cape Flyer intercity service between Boston and Hyannis. It is also possible that PAR might elect to operate the service for NHDOT. These political and institutional considerations have not been fully explored in this Study.

It is likely that service implementation would involve the NHRTA. The NHRTA was legislatively created in 2007 as a mechanism to implement passenger rail service in the state, especially between Boston and Manchester and to stand as a liability buffer between the service and the state. It acts under a Memorandum of Understanding with NHDOT to promote passenger rail. The NHRTA was given bonding authority, but has no independent source of revenue that would allow it to issue (or retire) bonds that it might issue. The 28-member Board of Directors represents potential host communities and state government; new members are to be added if service expands to areas not already represented. It is notable that many, if not most, state-supported passenger rail services are operated through an independent authority rather than directly by the state DOT. Such authorities, among other considerations, provide a liability buffer between the railway operation and the state.

The Study team has conferred with NHDOT and the NHRTA concerning their potential roles in operating passenger rail service, but until funding is identified, no commitments have been made concerning the mechanism for management and oversight of the railway service. NHDOT and MassDOT have conferred extensively concerning their possible operation of passenger rail service in the state. Most of those discussions have focused on extensions of MBTA commuter rail service north into Manchester, but Massachusetts expressed willingness to cooperate with an intercity passenger rail service operated by others. Massachusetts in general is quite supportive of any new Boston-based rail services, including those that cross interstate borders.

PAR entered into an engineering agreement with NHDOT to help manage the Study and is working with MassDOT and Amtrak on the provision of new intercity passenger rail services elsewhere in New England. They have been generally supportive of the project and accommodating to the Study team.

13.2 Finance[33]

Implementation of intercity passenger rail service in the Capitol Corridor will require decisions about how to pay for the service. Two types of costs must be considered:

- Costs of implementing the new service – either via buying more rail cars, operating longer trains, or constructing new rail infrastructure; referred to as capital costs, these are incurred up-front, before revenue service can begin
- Costs to operate and maintain the service, referred to as O&M costs; these costs occur annually once service has begun

This portion of the SDP identifies different sources of funds that can be used to fund these two types of costs. All funding options focus on ways to leverage available federal funds. The federal funds of most interest are those considered "discretionary" in nature; in other words, they would not otherwise be available to New Hampshire for other purposes. The majority of discretionary federal funds are available to cover capital costs. To a far lesser extent, other types of federal dollars – so called "formula funds" – are available to pay for O&M. Receipt of federal funds is subject to a variety of eligibility rules, and most federal funds must be "matched" by state and/or local funds. A typical minimum non-federal match requirement is 20 percent, but many programs in practice require a 50 percent match for discretionary funds (20 percent is more typical of formula funding schemes).

Given the local match requirement, this assessment also identifies potential state and local sources of funds that could provide this match.

No recommendation on preferred sources of funds is made as part of this assessment. Each option identified and evaluated will be subject to more discussion and decision-making once an alternative is identified as the preferred project for detailed development and ultimate implementation.

13.3 Passenger Rail and Public Transportation Funding in the U.S.

To provide context for understanding how public surface transport projects are funded across the U.S., this section describes how other agencies have paid for new public transportation projects. A very broad range of funding sources is used to pay for the capital and O&M costs of projects across the country. As noted above, federal funds typically contribute a fairly large share of transit project capital costs; this section focuses on the non-federal (state/local) sources of funding typically used to match federal dollars.

13.3.1 Common Sources of State Funding

Most state transit funding comes from General Fund appropriations, or through traditional taxes and fees, such as motor fuel taxes, sales taxes, and vehicle fees. State transit funding provides both operating

[33] For more information on project finance, see Appendix 3 to the Capitol Corridor AA Final Report (Task 3 Financial Plan)

assistance and capital funds, but only a few states provide dedicated funding either for capital expenses (Arkansas, Idaho, Kentucky, and Nevada) or operating expenses (Maine, South Dakota, and Wisconsin).

13.3.2 Common Sources of Local Funding

Local transit funding is primarily provided through General Fund allocations, dedicated local option taxes and fees, and value capture mechanisms. Applying dedicated local taxes and value capture mechanisms for transit is dictated by enabling legislation that allows or restricts the use of these funding sources. Table 13.1 provides a description of common local funding options.

Table 13.1: Common Sources of Local Funding

Revenue Source	Popularity[34]	Comments
Sales tax	High	Dedicated sales tax rates typically range from 0.25 to 1.0 percent
Property tax	Medium	Some states provide enabling legislation that allows property tax revenues to be dedicated to public transport
Motor fuel tax	Low	Some local governments apply a tax on fuel to transportation
Vehicle fee	Medium-Low	Registration fees, driver license fees, car rental taxes, and tolls
Employer/payroll tax	Low	Taxes imposed directly on employers for the amount of gross payroll paid are not commonly applied at the local level
Utility tax/fee	Low	Mainly used for local roads and streets
Room/occupancy tax	Low	Typically dedicated to tourism or tourism-related facilities; can be tied to transportation investments needed to enhance visitor experience, mobility, and accessibility
General revenue	High	Funding provided by local governments for public transport services, whether through a jurisdiction's annual budget or an appropriations process
Value capture mechanism	Medium-Low	Special types of "property taxes" targeted to capture the benefits of services that improve property development; typically low (less than five percent) yield relative to project cost
Impact fees	High	One-time charges to developers on new development; commonly used for roads, seldom for public transport
Tax Increment Financing	Medium-Low	Specific, common value capture mechanism; additional levies typically pledged to bonds issued to finance new transport services
Special assessment districts	Medium-Low	Another value capture mechanism; additional property taxes dedicated to new services for the district
Joint development	Medium-Low	Partnership between the rail agency and a private developer, commonly applied to TOD on land at or adjacent to train stations

13.3.3 Recent History in Passenger Rail Funding

To provide context for understanding how a passenger rail investment in the Capitol Corridor might be funded, information was assembled on eight new commuter or intercity rail systems that have opened in the U.S. over the past 15 years, as shown in Table 13.2.

[34] "Popularity" indicates how commonly used to finance major public transport investments like new passenger rail services

Table 13.2: New Commuter Rail Systems in the U.S. and Primary Capital Funding Sources

System	Location	Year Opened	Length (mi)	Federal	State	Local General	Sales Tax	Other Local
Sounder Commuter Rail	Puget Sound, WA	2000	33	●			●	●
Rail Runner Express	Albuquerque, NM	2006	97		●			
Music City Star	Nashville, TN	2006	32	●	●	●		
FrontRunner	Salt Lake City, UT	2008	44				●	
Northstar Line	Minneapolis, MN	2009	40	●	●	●		●
Capital MetroRail	Austin, TX	2010	32				●	
Westside Express Service	Portland, OR	2009	15	●		●		
A-Train	Denton County, TX	2011	21				●	●

Capital funding for these projects comes from a variety of sources. The most common source, used in half of the projects, is FTA Section 5309 New Starts funding, which accounted for an average of 43 percent of these projects' capital costs. One project, the Rail Runner Express extending between Albuquerque and Santa Fe, was funded entirely through state bonds backed by state road and highway revenues, including gasoline and diesel fuel taxes and federal highway aid. Local funding was more diverse: three systems used General Funds, mostly from local counties. Four projects used bonds backed by local sales taxes. Other local funding sources include a motor vehicle excise tax by Sounder Commuter Rail, and road tolls, which paid for 80 percent of the A-Train capital costs. The Northstar Line in Minneapolis received a contribution from the Minnesota Twins major league baseball team, helping to fund the terminal station next to Target Field.

For operating costs, local sales taxes are the most common primary source, used by six of the eight new rail systems: Sounder Commuter Rail (Puget Sound, Washington), Rail Runner Express (Albuquerque, New Mexico), FrontRunner (Salt Lake City, Utah), Northstar Line (Minneapolis, Minnesota), Capital MetroRail (Austin, Texas), and A-Train (Denton County, Texas). The Westside Express Service in Portland, OR is primarily funded through a payroll tax. Operating costs for the Music City Star in Nashville< Tennessee are primarily funded through federal grants and contributions from Metro Nashville.

It is also useful to consider how other passenger rail projects in the Northeast have been funded, particularly projects that represent extensions of MBTA's system. For projects wholly located within the Commonwealth of Massachusetts, funding for extensions has been provided by a mix of state and federal sources:

- Extension of peak-period commuter rail service from Framingham to Worcester was completed in 1994 and paid for with MBTA funds. Off-peak service was added in 1996, and a number of infill stations were added in 2000 and 2002 with no federal contribution.
- The 27.6-mile Greenbush Line to Scituate was a state air quality commitment project that opened for service in 2007. The $534 million project was also paid for with MBTA funds (no federal contribution).
- Half of the capital costs of improvements to the Fitchburg commuter rail line were paid for with an FTA Section 5309 Small Starts grant; the other half was paid for by state transportation bond proceeds. A 4.5 mile extension to a new Wachusett station was paid for by a USDOT

Transportation Investment Generating Economic Recovery (TIGER) grant (see Appendix 3 to the AA Final Report). Construction is underway with completion expected in 2015.

Intercity passenger rail service between Portland, Maine and Boston was restored in 2001. The construction cost of approximately $66 million was paid for by Congressional appropriations matched by state and local sources. Today, operation of the service is paid for through fares, which account for just under 50 percent of operating costs, federal funds allocated to operations, an annual subsidy from Maine of approximately $8 million, and an in-kind contribution from Massachusetts consisting of trackage rights. New Hampshire, which has three *Downeaster* stations in Exeter, Durham-UNH, and Dover, does not contribute financially.

Extensions of MBTA service south into Rhode Island have been implemented in accordance with the "Pilgrim Partnership," a 1989 cooperative agreement between the MBTA and Rhode Island Department of Transportation (RIDOT). These have included extension of MBTA commuter rail service to Providence, which was funded by RIDOT in part with "earmarks" in transportation appropriation bills (transportation earmarks have subsequently been prohibited by federal law) and state funds. In exchange for operation of the service by MBTA, RIDOT conveys its portion of federal formula funds to MBTA. Extension further south to Wickford Junction was paid for by an FTA Section 5309 Small Starts grant (50 percent of capital costs) and the remainder with a mixture of federal formula funds and state bonds.

In all cases, both nationally and in the Northeast, state sources of funding have been an integral part of each project's financial plan, including both construction and ongoing operations.

13.4 Annual Funding Needs

This section reviews the capital and O&M costs needed to construct and operate the Intercity 8 option. Capital and O&M costs were estimated in 2014 dollars.

A four-year construction period is assumed, beginning in 2019. The annual O&M costs for each alternative were also estimated based on costs for similar services provided elsewhere in New England.[35]

- Capital Costs (2014): $256.5 million
- Capital Costs (Year-of-Expenditure): $316.9 million
- Annual O&M Costs: $7.7 million

[35] See Section 11: Forecast Operating Costs and Revenues for more details

13.5 Federal Funding Sources

This section describes the sources of federal funding that might be used to help pay for intercity passenger rail service in the Capitol Corridor. A key objective of any Capitol Corridor project financial plan will be to leverage federal sources to the greatest extent possible

13.5.1 Federal Funding Sources and Financing Tools

Within the USDOT, the FRA administers the Railroad Rehabilitation and Improvement Financing (RRIF) program, which can be used for passenger rail projects, and in the past it has provided capital funding through the High-Speed Intercity Passenger Rail (HSIPR) program. The FTA administers the primary funding programs available for public transportation investment. It has funded intercity passenger rail programs, most notably the *Downeaster* service running between North Station in Boston and Brunswick, Maine. The FHWA administers some federal-aid highway programs with flexible provisions that allow the transfer of funds for public transportation investments.

In addition, federal finance tools are available that can be used to advance project implementation by leveraging future revenue streams of dedicated funding.

This section summarizes potential federal funding and financing tools and their eligibility to fund Intercity 8 option. Examples of other projects that have used these sources as part of their funding plan are identified. Table 13.3 provides a high-level summary of the possible federal funding sources and tools discussed in this section.

Table 13.3: Federal Funding Sources and Tools

Funding Source	Capital, O&M, Both	Eligible Modes	Comments
FHWA Congestion Mitigation and Air Quality Improvement Program (CMAQ)	Both	Commuter Rail Intercity Rail Intercity Bus	Flex
FRA HSIPR	Capital	Intercity Rail	No funding currently available
USDOT TIGER	Capital	Commuter Rail Intercity Rail	No funding currently available
USDOT Transportation Infrastructure Finance and Innovation Act (TIFIA)	Capital	Intercity Rail Commuter Rail Intercity Bus	Loan Program
FRA RRIF	Capital	Intercity Rail Commuter Rail	Loan Program

13.5.2 FHWA Congestion Mitigation and Air Quality Improvement Program

The FHWA CMAQ program funds transit system capital expansion and improvements projected to realize an increase in ridership, travel demand management strategies and shared ride services, and pedestrian and bicycle facilities. Projects must have a transportation focus, reduce air emissions, and be located in or benefit an air quality nonattainment or maintenance area. Funding is distributed based on a formula that considers the severity of air quality problems. The federal share is 80 percent for most CMAQ projects.

In FY2013, New Hampshire received $10.3 million in CMAQ funds. Using these funds for a project in the Capitol Corridor would require reallocation of some portion of the total New Hampshire apportionment. Under current rules, CMAQ funds can be used for the project's capital expenses, as well as operating costs, for a limited period of time. Operating assistance is limited to certain activities, including new transit, commuter, and intercity passenger rail services. Under the Moving Ahead for Progress in the 21st Century (MAP-21) Act, the operating funding period was extended from three to five years.

13.5.3 FRA Discretionary Programs

FRA occasionally makes funding available through discretionary programs that provide grants to eligible projects through a competitive application process. For example, the HSIPR was created to make investments in a network of passenger rail corridors across the country. The program's objectives are to build new high-speed rail corridors, upgrade existing intercity passenger rail corridors, and lay the groundwork for future high-speed rail services through planning efforts. More than $10 billion in grant funding was provided after the enactment of the program through the Passenger Rail Investment and Improvement Act (PRIIA) of 2008, including a FY2010 grant of $2 million to the Capitol Corridor for engineering and environmental analysis. The program was highly competitive, with over $75 billion in total funding requests from 39 states, Washington D.C., and Amtrak. While the program is not currently funded and no new funding appears to be likely in the near-term (thus no applications are being accepted), the intercity rail alternative could be eligible for future grant solicitations should additional funding be allocated.

13.5.4 USDOT Transportation Investment Generating Economic Recovery (TIGER)

Another discretionary funding source is USDOT's TIGER program. Competitive grant applications are solicited on a periodic basis; there have been six rounds of funding since 2009, providing $4.1 billion to eligible road, rail, transit, and port projects. Rail and transit projects awarded TIGER funding have accounted for more than 40 percent of total awards to date. The average award for transit projects was $17.6 million. The last round of awards was announced in September 2014. Should another round of funding be made available, the commuter rail and intercity alternatives could be eligible projects.

13.5.5 USDOT Transportation Infrastructure Finance and Innovation Act (TIFIA)

The TIFIA program is a credit assistance program administered by USDOT providing direct loans, loan guarantees, and standby lines of credit. Surface transportation projects that cost $50 million or more are eligible, including those for state and local governments, transit agencies, railroad companies, special authorities, special districts, and private entities. Any transit project eligible for grant assistance under the transit title of the U.S. Code (chapter 53 of 49 U.S.C.) and intercity bus vehicles and facilities are eligible for TIFIA credit assistance. In addition, rail projects involving the design and construction of intercity passenger rail facilities or the procurement of intercity passenger rail vehicles are also eligible. The TIFIA loan or loan guarantee amount should not exceed 49 percent of eligible costs; for standby lines of credit, the limit is 33 percent of the project costs. Dedicated revenues for repayment are required. Tax revenues, including sales taxes, are a common revenue pledge for TIFIA. A total of $1.0 billion was authorized for this program in 2014.

13.5.6 FRA Railroad Rehabilitation and Improvement Financing (RRIF) Program

The RRIF is an FRA loan program enacted under the Transportation Equity Act for the 21st Century (TEA-21) that provides direct federal loans and loan guarantees to finance development of railroad infrastructure. Eligible applicants are railroads, state and local governments, government-sponsored authorities and corporations, joint ventures that include at least one railroad, and limited option freight shippers who intend to construct a new rail connection. Loans can cover up to 100 percent of project costs with interest rates equal to U.S. Treasury rates. The Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) made amendments to the program; no changes were included in MAP-21. There have been few RRIF loans: Out of $35 billion in authorized funds, only $1.7 billion in loans have been awarded through FY2012. Reasons for the program's underutilization include that unlike TIFIA, there is no federal subsidy; therefore, costs associated with FRA's review of the RRIF loan application are covered by the applicants. In addition to this investigative fee, the applicant also pays a credit risk premium unless collateral is provided. Other issues include long loan processing times and the perception that applicants bear the full risk of default.

Eligible projects include acquisition, improvement, or rehabilitation of intermodal or rail equipment or facilities; refinancing existing debt incurred for the purposes above; or developing or establishing new intermodal or railroad facilities. The NNEPRA, which operates the *Downeaster* passenger rail service between Brunswick and Boston, was approved for a RRIF loan in 2009, but this was foregone in favor of HSIPR grant funding awarded for the project.

13.6 Non-Federal Match Options for New Hampshire Services

This section reviews possible options for providing non-federal match for a transportation service investment along the NHML. These options were narrowed down from the longer list above, since some of the most commonly used sources of local funding are not available in New Hampshire. These include dedicated sales tax revenues (which is the most common source of local match in the U.S.), payroll taxes, and fuel taxes.

New Hampshire does not impose any sales or payroll taxes, and it assumed that they would not be implemented solely for a project on the NHML. Fuel taxes are constitutionally restricted in New Hampshire for use on construction, reconstruction, and maintenance of public highways.[36] Because of this, a rail project on the NHML would be ineligible for this source of funds, and a change to the constitution is not perceived to be possible.

For each funding option discussed below and summarized in Table 13.4, a definition is first provided, followed by an assessment of the feasibility and potential revenue estimate for each source. Ratings for feasibility reflect an assessment of 1) whether the source currently exists in New Hampshire; 2) whether

[36] Part II, Article 6-a of the New Hampshire Constitution

transit is an eligible expenditure for the funding source; 3) the extent of likely support for the source; and 4) actions (e.g., legislative) that would be required for use of the source as part of the project's financial plan to cover costs.

The amount of revenue that might be generated from each source also is estimated. Each estimated yield is subject to change with alternative input assumptions and charge rates. The range of annual yield rating estimates are greater than $5 million = High; $1-$5 million = Medium; less than $1 million = Low. Table 13.4 summarizes the funding options. In general, each of the feasible funding sources will require significant effort and commitment to implement. As potential sources are evaluated, it will be important to consider the level of required effort in the context of likely yield. While revenue estimates are provided for all options, sources with low feasibility are unlikely to be available given significant implementation challenges, and are not considered as part of potential funding approaches.

Table 13.4: Summary of Funding Options for Intercity 8

Funding Source	Feasibility	Yield	Annual Estimate (In Millions)	Comments
NH State Capital Program	High	High	$10.0	7.6% of 2014 debt payment (principal + interest)
NH Parking Fees	High	Low	$0.7	Based on $4.00 per day parking fee
Vehicle Registration Fees	Medium	High	$5.9	$5.00 fee on passenger vehicles and trucks statewide
Municipal Contribution	Medium	Medium	$1.0-3.0	$1 million/city with new stations; city discretion regarding source
Regional Greenhouse Gas Initiative (RGGI)	Medium	Low	$0.5	Based on historical awards
Property Tax	Low	High	$15.7	0.1 mill applied statewide
Lottery Revenues	Low	Medium	$3.7	5% of net proceeds
Passenger Facility Charges	Low	Medium	$1.0	½ of $1.50 passenger facility charge (PFC) increase beginning in 2016
Value Capture	Low	Low	--	Need more study to estimate

13.6.1 New Hampshire State Capital Program

New Hampshire State (Legislature/Governor) approves a capital budget every two years. The last approved budget, for 2014-2015, was $219.4 million (for all projects, including highways, which are paid for with restricted revenues, i.e., fuel tax and highway user fees). The next cycle to approve the budget is initiated in the fall (projects are submitted by November 15). The budget is approved on February 15th of odd numbered years (i.e., the next budget will be approved in February 2015).

The most recent budget included bond authority for the entire cost of the capital program ($219.4 million). Of this, $128.7 million are for projects funded with bonds that are repaid with unrestricted General Fund revenues.

For NHDOT, bonds for highway projects are repaid with highway revenues (restricted). The capital budget included $2.2 million in General Fund bonds for NHDOT's Aeronautics, Rail and Transit Division. The proceeds provide matching funds to Federal Aviation Administration (FAA) and FTA grants.

As of June 2013, the state had $963.2 million in outstanding general obligation debt, including bonds for highways and the University of New Hampshire.

Feasibility	*Yield*
▪ Existing source of funding for state capital investments through bonds repaid with unrestricted General Funds ▪ Currently providing matching funds to federal grants for NHDOT's Aeronautics, Rail and Transit Division ▪ Governor/Legislature support required ▪ Only for capital expenses	▪ Would need to assess feasibility of fully or partially providing Capitol Corridor project capital funding needs through the State Capital Program, while maintaining reasonable debt-to-state revenue ratios ▪ The largest single funding allocation from bond proceeds in recent years was for $38 million, which is less than 15 percent of total funding needed for most costly alternatives ▪ Assumes an annual allocation of $10 million in unrestricted General Funds to repay bonds issued through the capital budget to pay for construction of the selected alternative; at the current debt service level (FY2014 = $132.2 million), $10 million represents about 7.6 percent of unrestricted General Fund revenues required to repay bonds

13.6.2 Parking Fees

New parking facilities associated with the alternatives could generate funding to support O&M expenditures. Only the rail alternatives include planned new parking, so this potential revenue source is not available for the bus alternatives.

The methodology to estimate revenues is based on parking occupancy and the number of vehicles that use the parking facility in an average day. If most travel is work-related, chances are that most parking spaces are occupied by a single vehicle any given day, and the parking turnover rate would be low.

Feasibility	Yield
▪ Parking at rail stations will be provided, so parking would be considered a future available source for funding	▪ Based on data provided by Jacobs Engineering, an estimated 470 to 925 parking spaces would available at planned commuter and intercity rail park-and-ride lots, depending on the alternative; if fully occupied 240 days per year, with a per-day parking fee of $4.00, parking revenues would total between $0.5 million and $0.9 million annually; a midrange of parking yields $0.7 million annually; for comparison, most MBTA commuter rail park-and-ride facilities charge $4.00 per day; in Lowell, garage parking is priced at $5.00 per day

This fee could be extended to other park-and-ride facilities, specifically those used by riders of intercity bus service between New Hampshire and Boston.

13.6.3 Vehicle Registration Fees

New Hampshire currently collects vehicle registration fees at the state and local level that vary by type, size, value, and age of the vehicle. State fees are restricted to use on highways, but municipalities have more latitude on the use of at least a portion of their revenue.

Feasibility	Yield
▪ Changes to registration fees would require legislative action to modify Section 261:141 (Registration Fees)[37] and/or Section 261:153 (Municipal Permits for Registration)[38] of Title XXI (Motor Vehicles) in the state statutes ▪ State-level registration fees are constitutionally restricted to be used for construction and maintenance of public highways,[39] while local-level fees have a broader range of uses ▪ Fees are assumed to be applied statewide	▪ In 2011, nearly 840,000 passenger vehicle registrations and 334,000 truck registrations were processed in New Hampshire;[40] assuming a $5.00 fee statewide translates to approximately $5.9 million annually ▪ This yield assumes a small statewide increase; other assumptions could be made, including geographies covered – i.e., only the municipalities served by the project in the Capitol Corridor – and fee rates

13.6.4 Municipal Contributions

Cities often help pay for implementation and/or ongoing O&M of transit projects, particularly cities that receive a substantial new station that generates accessibility benefits and increases in development opportunities and property values. For this assessment, it is assumed that only cities that will have rail stations – Nashua, Manchester, and Concord, depending on the alternative – could make an annual contribution.

Feasibility	Yield
▪ Cities would have the flexibility to identify their own sources of revenue, whether an existing source or a new source associated more directly with the project, such as a tax increment financing district or some other value capture mechanism	▪ For purposes of this assessment, it is assumed that Nashua, Manchester, and Concord would contribute (e.g., $1 million annually) depending on the alternative/whether it includes a rail station in the municipality

[39] Part II, Article 6-a of the New Hampshire Constitution
[40] https://www.nh.gov/safety/documents/2011-annual-report.pdf

13.6.5 Regional Greenhouse Gas Initiative

Proceeds from the auction of RGGI emissions allowances in New Hampshire go to the Greenhouse Gas Emissions Reduction (GHGER) Fund. Ten percent of funds are set aside for a low-income residential energy reduction program; the remainder is awarded in grants through a Request for Proposal (RFP) process focused on electric and fossil fuel energy efficiency programs. A list of eligible programs includes nothing transportation-related, only buildings, although the list indicates eligibility is not limited to that list.[41]

As of 2013, New Hampshire had received more than $57 million in allowance auction revenues over five years.[42] Grant awards have ranged from as little as $8,000 to as much as $5 million.

No New Hampshire transportation project has yet been awarded grants from the GHGER Fund. In the 10 states participating in RGGI, one percent of CO_2 allowance proceeds have been used "for a wide variety of greenhouse gas reduction programs, including programs to promote the development of carbon emission abatement technologies, efforts to reduce vehicle miles traveled, and programs to increase carbon sequestration." Therefore, there is some precedent in at least one of these states to use these funds for a transportation project.

Feasibility	***Yield***
▪ Use of RGGI proceeds for transit improvements in the Capitol Corridor would need to be confirmed	▪ For the purposes of this assessment, it is assumed that a project in the Capitol Corridor could receive annual grants of the same order of magnitude of historical grant awards through this program, or approximately one-half million per year

[41] https://www.puc.nh.gov/SustainableEnergy/GHGERF.htm
[42] http://www.rggi.org/docs/Investment_of_RGGI_Allowance_Proceeds.pdf

13.6.6 Property Tax

Four types of property taxes are assessed in New Hampshire: town tax, local education tax, state education tax, and county tax. Property taxes are a common source of funding for transit projects in the U.S.

Feasibility	Yield
▪ Major existing local source of revenue ▪ Currently, all state-levied property taxes are dedicated to education; using this revenue source for the Capitol Corridor would require legislative action	▪ In 2012, total assessed property value in New Hampshire was $156.6 billion;[43] the weighted statewide average of property tax rates was 20.71 mill ▪ Applying a tax rate of 0.1 mill (10 cents per $1,000 in assessed value) would generate approximately $15.7 million per year

13.6.7 Lottery Revenues

New Hampshire has the oldest legal lottery in the U.S. The state participates or hosts a variety of lottery games, including scratch tickets and draw games.

Feasibility	Yield
▪ Currently, all net lottery revenues in New Hampshire are dedicated to the state education fund ▪ A new lottery game dedicated to the Capitol Corridor or more broadly for transportation use would likely be needed, rather than diverting revenues from existing games; in either case, legislative action would be required	▪ Lottery revenues in New Hampshire, net of prizes and administrative expenses, totaled $74.3 million in 2013 ▪ Five percent applied to a Corridor project would result in $3.7 million per year

13.6.8 Passenger Facility Charges

Manchester Airport currently collects the maximum $4.50 per enplanement PFC. Eligible projects include those improvements related to enhancing airport safety, capacity, security, and environmental concerns. Under its current approvals, the airport is authorized to collect PFC through November 2022.

In the near-term, PFC revenues at the $4.50 level are fully committed, including payments to debt service on outstanding bonds, approved pay-as-you-go projects for which the airport has not yet reimbursed itself, and additional projects identified in the Capital Improvement Program.

[43] New Hampshire Department of Revenue Administration

Feasibility	Yield
▪ In the current FAA reauthorization proposals, the cap on PFC levels may be raised beyond the $4.50 level to provide additional funding available outside of FAA's Airport Improvement Program (AIP); beginning in FY2016, the airport is assumed to increase its PFC level to $6.00 and additional collections are assumed to be used on a pay-as-you-go basis for future projects[44] ▪ It appears possible, but difficult, for a transit project to use this funding source given restrictions on project eligibility and the existing cap on PFC levels; if an eligible project could be developed, negotiations would be needed with the airport and FAA to include it in the airport's future capital plan	▪ Enplanements have fallen since their 2.2 million peak in 2006, and totaled 1.36 million in 2011;[45] an additional $1.50 PFC would create an estimated $2 million annually; if half of this increment could be directed towards a corridor project, then this would provide $1 million annually to the project pending eligibility considerations

13.6.9 Value Capture

Value capture includes revenue mechanisms such as impact fees, tax increment financing, and special assessment districts. Without specifics on future development and potential development to result from implementation of new transit corridor service, it is difficult to generate estimates for impact fees or tax increment financing. An option is to estimate how much revenue could be generated through a special assessment district. Data needs/basic assumptions (for special assessment district example) include the following:

- Taxable property values in the cities/towns served by each corridor alternative (New Hampshire Department of Revenue), or within some agreed upon distance from the corridor and/or station locations
- Historical trends on property value growth
- Property tax rate
- Alternatively, calculate tax rate, based on capital and O&M needs

It should be noted that changes in development patterns and property values take time – and often considerable time – to be realized based in large part on market conditions and demand. Therefore, value capture would not be a near-term source of revenue for the Intercity 8 project.

[44] http://www.flymanchester.com/sites/default/files/public-documents/ManchesterAirportMasterPlanUpdate.pdf
[45] http://www.flymanchester.com/sites/default/files/statistics/MHTEnplanements2000-2012.pdf

13.6.10 Fares

The O&M costs for Intercity 8 will be offset by the fares collected from riders. The Study team estimates that the Intercity 8 service would cover approximately 40 percent of its operating costs from fare revenues (Table 13.5).

Table 13.5: Annual Fare Revenue and Farebox Recovery Ratio (2012$)

Annual O&M Cost (A)	$7.7 million
Fare Revenue (B)	$3.2 million
Required Operating Support (A-B)	$4.5 million
Farebox Recovery Ratio (A-B)/A	41 percent

14 Summary

While final decisions on any major public transportation investment on the NHML will necessarily incorporate a broad range of considerations including benefits and impacts, the ability to identify stable and reliable sources of revenue will be critical to the advancement of passenger rail service in the Capitol Corridor. Leveraging available discretionary federal funds will be a key objective of any future funding plan.

This section summarized key findings regarding the potential to leverage federal funds for Intercity 8. Suggestions were also provided on other sources of potential revenue to provide match for federal funds. Any new source of revenue to help pay for a new intercity passenger rail service will be subject to considerable review and input by New Hampshire officials and corridor stakeholders.

Intercity 8 would rely on federal programs, namely FRA's HSIPR Program. However, the HSIPR currently has no funding available. For purposes of this assessment, it is assumed that half pf the capital costs of the project might be paid for by a future HSIPR appropriation. With Intercity 8 being the most costly project considered and with the considerable uncertainty regarding available federal funding, this alternative likely would place a high burden on other state sources. Local sources of funding could include CMAQ, parking revenue, and contributions for the three municipalities with stations (Nashua, Manchester, and Concord).

To help understand what this might mean in terms of an annual "bill" to New Hampshire for Intercity 8, debt service is calculated for the New Hampshire share of capital costs as well as construction payments made in advance of receipt of FTA funds. This annual debt service, which lasts only for the period of the bonds issued, is then added to the annual operating cost for Intercity 8, net of fares. The annual debt service must be viewed as a best case, since agreements with Massachusetts on cost sharing arrangements are subject to additional discussion and negotiation.

Table 14.1 is a summary of the Intercity 8 Financial Assessment. All numbers are subject to change as additional work and coordination with potential funding partners is advanced.

Table 14.1: Intercity 8 Financial Assessment Summary (In Millions)

Infrastructure Cost	$233.2
Rolling Stock Cost	$23.3
Total Project Value	**$256.5**
Potential Federal Grant	$128.2**
New Hampshire Share (after federal contributions)	**$128.2**
Annual Payment to Retire NH Share[46]	$10.3
Annual Operating Cost	$7.7
Annual Passenger Revenue	$3.2
Required Operating Support	$4.5
Annual NH Cost	**$14.8**

**Note: Capital costs are in 2014$ and operating costs are based on 2012$ unit costs. Ridership and fare rates are current to 2014. Therefore, estimates of operating costs and required support may vary when operating unit costs become available for 2014$.*
*** Assumes that 50% of capital funds are provided under FRA's HSIPR program*

[46] Assumes 20-year bonds at five percent to retire the state/local match; short-term financing to cover lags in the federal reimbursement process during the construction process is not included in this estimate; the interest on the short term debt at three percent per annum to cover a $128.2 million grant would average approximately $1.9 million per year over a four-year construction period

Appendix B: Detailed Cost Estimates of Stations

Table B.1: Cost Factors Used to Calculate Proposed Station Capital Costs

Description	Materials			Material Cost Total	Labor		Total Direct Cost	Allocation Factor	Calculated Unit Cost
	Quantity	Units*	Unit Costs		Man-Hrs	Cost ($)			
SITE WORK									
Remove & Dispose Existing Pavement	1,988	SY		-	95	$33,987	$33,987	0	$0
Remove & Stock Curbing	160	LF		-	85	$2,040	$2,040	0	$0
Clearing & Grubbing	3.17	Acre		-	85	$4,311	$4,311	Half-fixed, half-variable based on parking spaces	$2,156 + $6 per space
Cut, Cap, & Abandon Monitoring Well	2	EA		-	85	$340	$340	1 if contaminated, 0 if not	$340
Site Preparation – Remove & Dispose of Boulders	4	EA	$50.00	$200.00	110	$880	$1,080	0	$0
Cleaning & Sweeping Roadway	109	HR		-	120	$13,080	$13,080	Unit	$13,080
Water for Dust Control	44,500	GL	$0.04	$1,780.00	85	-	$1,780	Unit	$1,780
Erosion Control System (Straw Bale & Silt Fence)	4,677	LF	$1.00	$4,677.00	72	$15,153	$19,830	Unit	$19,830
Silt Sack	23	EA	$100.00	$2,300.00	72	$1,656	$3,956	Unit	$3,956
Mobilization & Demobilization for Bulk Excavation	1	LS	$6,000.00	$6,000.00	110	-	$6,000	Unit	$6,000
Unclassified Excavation	18,768	CY		-	110	$92,902	$92,902	Unit	$92,902
Unclassified Excavation – Handling & Off-Site Disposal	22,800	TN	$18.00	$410,400.00	110	-	$410,400	1 if contaminated, 0 if not	$410,400
Dispose of Contaminated Soil at In-State Lined Landfill	630	TN	$35.00	$22,050.00	110	$3,119	$25,169	1 if contaminated, 0 if not	$25,169
Dispose of Contaminated Soil at In-State Recycling Facility	630	TN	$75.00	$47,250.00	110	$3,119	$50,369	1 if contaminated, 0 if not	$50,369
Rock Excavation	1,632	CY		-	110	$31,416	$31,416	Unit	$31,416
Rock Excavation – Haul & Disposal	2,203	TN	$15.00	$33,048.00	110	-	$33,048	Half-fixed, half-variable based on parking spaces	$16,524 + $46 per space
Soils Testing Services (LSP, Licensed Site Professional)	364	HR		-	110	$40,040	$40,040	Half-fixed, half-variable based on parking spaces	$20,020 + $56 per space
Soil Sampling & Testing (Assume 50-ft Grid)	146	EA	$180.00	$26,280.00	150	-	$26,280	Half-fixed, half-variable based on parking spaces	$13,140 + $37 per space
Grading	364,800	SF		-	85	$124,032	$124,032	Half-fixed, half-variable based on parking spaces	$62,016 + $172 per space
Ordinary Fill (Processed Gravel)	14,540	CY	$0.80	$11,632.00	110	$151,943	$163,575	Half-fixed, half-variable based on parking spaces	$81,788 + $227 per space
Crushed Stone – Platform	50	CY	$30.00	$1,500.00	110	$880	$2,380	Half-fixed, half-variable based on parking spaces	$1,190 + $3 per space
Wetland Replication Area	3,000	SF	$6.00	$18,945.00	85	$11,820	$30,765	Square feet of wetlands	$10.26
Subtotal				$586,062.00	5,325	$530,718	$1,116,780		
Subtotal Retaining Walls				$943,440.00		$1,265,872	$2,209,316	Based on site	$220,932
Subtotal Drainage				$204,092.00	2,301	$198,634	$402,726	Half fixed half variable based on parking spaces	$201,363 + $559 per space
Subtotal Site Work – Parking Lot & Drop-Off Area				$862,032.00	4,123	$375,564	$1,237,598	Parking spaces (*10 for garage)	$3,438
Subtotal Landscaping				$183,659.00	3,459	$250,968	$434,626	Quarter fixed/3/4parking spaces	$108,657 + $905 per space
STATION ELEMENTS									
Subtotal Rail Road Components (Lead Track at Station)				$233,283.00	1,163	$145,611	$378,894	Side tracks	$378,894
Subtotal Platforms				$584,900.00	2,037	$275,225	$860,125	Half platforms	$430,063

Appendix C: Detailed Cost Estimates of Layover Facilities

Table C.1: Cost Factors Used to Calculate Proposed Layover Facility Capital Costs

Description	Materials				Labor				Total Direct Cost	Allocation Factor	Calculated Unit Cost
					Man-Hrs		Cost ($)				
	Quantity	Units	Unit Costs	Total	Unit	Total	Unit	Total			
SITE WORK											
Miscellaneous Site Cleaning & Clearing	1	LS	$2,000.00	$2,000				-	$2,000	Track Feet	$0.21
Erosion & Sedimentation Control (Hay Bale & Silt Fence)	8,180	LF	$1	$8,180	0.045	368	72	$26,503	$34,683	Track Feet	$3.59
Silt Sack	15	EA	$100	$1,500	1	15	72	$1,080	$2,580	Track Feet	$0.27
Temporary Construction Access Road	56	ton	$68	$3,808	0.09	5	85	$428	$4,236	Track Feet	$0.44
Clearing & Grubbing	4	Acre	-	-	16	57	85	$4,811	$4,811	Track Feet	$0.50
Stripping & Stockpiling of Topsoil	745	CY	-	-	0.039	29	110	$3,155	$3,155	Track Feet	$0.33
Ordinary Excavation	52,812	CY	-	-	0.039	2,033	110	$223,659	$223,659	Track Feet	$23.17
Unclassified Excavation – Handling & Off-Site Disposal	64,170	TN	$18	$1,155,060			110	-	$1,155,060	Track Feet	$119.63
Dispose of Contaminated Soil at In-State Lined Landfill	1,780	TN	$35	$62,300				-	$62,300	Track Feet if contaminated, otherwise zero	$6.45
Dispose of Contaminated Soil at In-State Recycling Facility	1,780	TN	$75	$133,500				-	$133,500	Track Feet if contaminated, otherwise zero	$13.83
Rock Excavation	1,000	CY		-	0.175	175	110	$19,250	$19,250	Zero	$0
Rock Excavation – Haul & Disposal	1,350	TN	$18	$24,300			110	-	$24,300	Zero	$0
Soils Testing Services (LSP)	896	HR		-	1	896	110	$98,560	$98,560	Track Feet if contaminated, otherwise zero	$10.21
Soil Sampling & Testing (Assume 50-ft Grid)	194	EA	$180	$34,920				-	$34,920	Track Feet if contaminated, otherwise zero	$3.62
Tree Removal – Includes Stumps	10	EA	$1,200.00	$12,000			85	-	$12,000	Zero	$0
Processed Gravel Ordinary Fill	21,100	CY	$0.8	$16,880	0.095	2,005	85	$170,383	$187,263	Track Feet	$19.40
Gravel Borrow Sub-Base (Processed Gravel)	28	CY	$0.8	$22	0.095	3	85	$224	$247	Track Feet	$0.03
Grading & Finishing	483,958	SF		-	0.004	1,936	85	$164,546	$164,546	Track Feet	$17.04
DIRECT COST SUBTOTAL				$1,454,470		7,521		$712,599	$2,167,070	Total	
Subtotal Roadways & Walkways Pavements				$708,237		2,710		$220,993	$929,230	Storage Positions	$154,872
Subtotal Landscaping				$305,980		2,615		$188,294	$494,274	Number of track feet	$51.19
Subtotal Site Work – Drainage				$35,943		538		$46,357	$82,299	Number of track feet	$8.52
TRACK WORK											
Surface & Align Track	9,655	TF		-	0.1	966	145	$139,998	$139,998	Track Feet	$14.50
Tie with Assemblies	5,945	EA	$100	$594,500	0.18	1,070	145	$155,165	$749,665	Track Feet	$77.65

Project Purpose and Need Summary

Increasing transportation demand and growing concerns about mobility, economic development, and quality-of-life have led New Hampshire and Massachusetts citizens and officials to explore transit and/or intercity passenger rail service options in the 73-mile corridor (Capitol Corridor) between Boston, Massachusetts and Concord, New Hampshire.[1] The purpose of this Capitol Corridor Rail and Transit Alternatives Analysis (AA) Study is to evaluate a diverse set of rail and bus options to improve connectivity by leveraging existing transportation infrastructure, including Pan Am Railways (PAR), Route 3, and I-93. Investment in an improved transportation strategy is needed for several reasons:

- Projected population growth will result in increased roadway congestion
- New Hampshire's existing transportation network does not effectively connect existing modes
- The regional economy is singularly dependent on roads for movement of goods and passengers
- Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents
- Young New Hampshire professionals are leaving the area to be closer to employment and cultural/social opportunities associated with larger urban centers
- New Hampshire's growing senior population needs more "car-light" mobility options
- Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life
- The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences

Task Objectives

EA Objectives

This Environmental Assessment (EA) follows the Service-level National Environmental Policy Act of 1969 (NEPA) process as outlined in the NEPA guidance from Federal Railroad Administration (FRA). Service-level NEPA "typically addresses the broader questions relating to the type of service(s) being proposed, including cities and stations served, route alternatives, service levels, types of operations (speed, electric, or diesel powered, etc.), ridership projections, and major infrastructure components." This Study, if it advances, will be followed by a future analysis, which may be an Environmental Impact Statement (EIS), EA, or Categorical Exclusion (CE), depending on project details and the significance of the impact.

[1] The report "Task 2: Project Purpose and Need" (Appendix 2 to the AA Final Report) provides an in-depth evaluation of the Capitol Corridor's historical, current, and future state, and how Massachusetts and New Hampshire citizens would benefit from a transit investment strategy responsive to transportation needs and the region's economic, social, and environmental climate

This EA addresses build and no-build alternatives for an Amtrak-operated (or similar) intercity rail service (Intercity Rail 8) between Boston, Massachusetts and Concord, New Hampshire. Three alternatives were specific to intercity passenger rail service and the Intercity 8 alternative was carried forward into detailed analysis (see Appendix 9, Service Development Plan, to the Capitol Corridor AA Final Report). Intercity 8 would operate eight trips per day between Boston North Station and Concord. The four daily round trips over the 73-mile route would stop at five intermediate stations (Manchester, Manchester-Boston Regional Airport [Manchester Airport or MHT], Nashua, Lowell and Woburn). End-to-end trip time would be approximately 96 minutes. The service would operate at a maximum speed of 75 mph between Bedford/Manchester Airport and Nashua and 70 miles per hour (mph) at many other locations and is expected to attract 172,645 passengers per year.

Service could be extended with possible connections to private bus services for North Country destinations. No changes are proposed to express bus service for commuting to Boston via I-93 or Route 3. Local bus service to the intercity rail stations could be offered, but would not be integral to the service design. A Boston Express (BX)/Concord Coach/Intercity Rail fare integration scheme similar to that employed by the Amtrak *Downeaster* at Portland, Maine could be employed at the Concord and Manchester stations that would be shared by both intercity rail and coach bus services.

The purpose of this EA is to identify potential environmental, social, and economic impacts associated with the proposed Intercity 8 project and determine appropriate mitigation measures (see Table 1 for a summary). As this is a Service-level NEPA document, some resources will not have mitigation determined at this level of analysis.

Table 1: Summary of Intercity 8 Resource Impacts and Proposed Mitigation

Resource	Impact	Mitigation
Air Quality	Improved air quality through vehicle trips shifting to intercity rail	A number of sustainable mitigation measures that can be implemented to improve air quality
Noise and Vibration	707 moderate noise impacts and 75 severe impacts due to warning horns; four potential daytime construction impacts and up to 324 potential nighttime construction impacts have been identified as a result of the analysis conducted pursuant to Federal Transit Administration (FTA) guidelines; no vibration impacts are expected	Mitigation measures will be applied for each impact during the next phase of Study
Hazardous Waste Sites	Short-term adverse impacts may occur during construction of rail and station sites due to potential for movement of contaminated soils or material	Phase I Environmental Site Assessments (ESAs) should be completed for each property acquired to be eligible for Landowner Liability Protections (LLPs)
Water Quality	Negligible to minor, short-term, localized impacts during construction activities	All impacts will be mitigated through Best Management Practices (BMPs), including improvements to drainage and stormwater management
Wetlands	▪ No impact to wetlands in most areas of the corridor and minor temporary and permanent impacts to jurisdictional wetland resource areas in a few discrete areas of the corridor ▪ The Bedford/Manchester Airport station has several	As more detail is developed in the project's next phase, these impacts will be defined in greater detail; any wetland impacts would be subject to state and federal permitting requirements

Resource	Impact	Mitigation
	wetlands and watercourses ▪ North of Ray Wieczorek Drive, the majority of the site is forested wetland ▪ South of Ray Wieczorek Drive, there are two small forested wetlands and one emergent/scrub-shrub wetland ▪ Minor temporary impacts may occur during construction activities	
Threatened and Endangered Species	None	At this level of the project, neither state agency has ruled on whether the project would qualify as a "take" under the regulations (this will be confirmed in future analyses)
Floodplains	Minor to negligible impacts to floodplains	In locations where floodplain elevations will be altered, the project will provided compensatory floodplain storage; through mitigation, adverse impacts to floodplains will be kept to a minimum
Energy Resources	Beneficial impact: Diverting trips from vehicles to passenger rail will reduce the overall Vehicle Miles Travelled (VMT) and greenhouse emissions; during construction, the project would consume energy through the processing of materials and construction activities	All impacts during construction will be addressed in the next level of analysis
Visual Resources	For work associated with the rail line, no impacts; for work associated with the stations and layover facility, negligible impacts	All mitigation measures associated with visual resource impacts will be addressed in the next level of analysis
Accessibility	None	None
Property Acquisition	Minor impacts: Station development would require acquisition of two privately held parcels	All mitigation measures associated with property acquisitions will be addressed in the next level of analysis
Land Use	Moderate beneficial impacts associated with increasing transit-supportive development around stations, improving access to jobs, reducing the reliance on vehicles for trips, attracting employers to New Hampshire, retaining and attracting employers from New Hampshire to Boston, and improving residency location choice in New Hampshire for commuters to Boston or regional jobs	None
Environmental Justice (EJ)	Major beneficial impacts for those EJ populations within proximity to proposed stations in Concord, Manchester, and Nashua, as the project provides increased access to transportation options within the corridor	None
Public Safety	Beneficial impact through mitigation and upgraded safety features	A number of mitigation measures are recommended to improve the safety of the 35 at grade crossings: the Centralized Traffic Control (CTC) signal system would be renewed and upgraded; all new equipment for the Automatic Highway Warning Devices (AHWD) will be installed; it is assumed that Positive Train Control (PTC) will be in-place by the time this route is operational
Cultural Resources	No impact on Historic Architectural Resources; minor to negligible impacts to Archeological Resources	As the area's archeological potential is generally high, precautions will be put in-place to mitigate adverse impacts to resources

Resource	Impact	Mitigation
Park and Recreations	Unknown impact on Section 4(f) Resources in the corridor at the Service-level of analysis	To be determined in the next level of analysis
Socioeconomics	Beneficial impact on New Hampshire economics by potentially generating the following: ▪ 1,600[2] new residential units ▪ 819,000 square feet of commercial space ▪ 2,480 new station area jobs in 2030 and beyond, plus 1,100 other new jobs due to expansion of the economy ▪ 350 new jobs over the construction period (2019-2022) and 2,460 jobs related to new real estate development between 2021 and 2030 ▪ Real estate development would add $750 million to the state's output between 2021 and 2030	None
Transportation	Beneficial impact on rail options and mobility in the corridor by increasing transportation options	None
Indirect Effects and Cumulative Impacts	Indirect Effects: Beneficial long-term effects due to induced growth and development around station locations Cumulative Impacts: Incremental beneficial impact on the environment through greater access to transportation options and reduction in VMT within US Route 3 and I-93 corridors	

Public Involvement Objectives

The Capitol Corridor AA Study developed a robust public involvement program designed to solicit input from a broad, diverse range of players who have a stake in the future of passenger rail in New Hampshire. The project team conducted 91 stakeholder meetings, three Project Advisory Committee (PAC) meetings, and three public meetings (Concord, Manchester, and Nashua) since project onset. The main objectives of the public and stakeholder outreach are as follows:

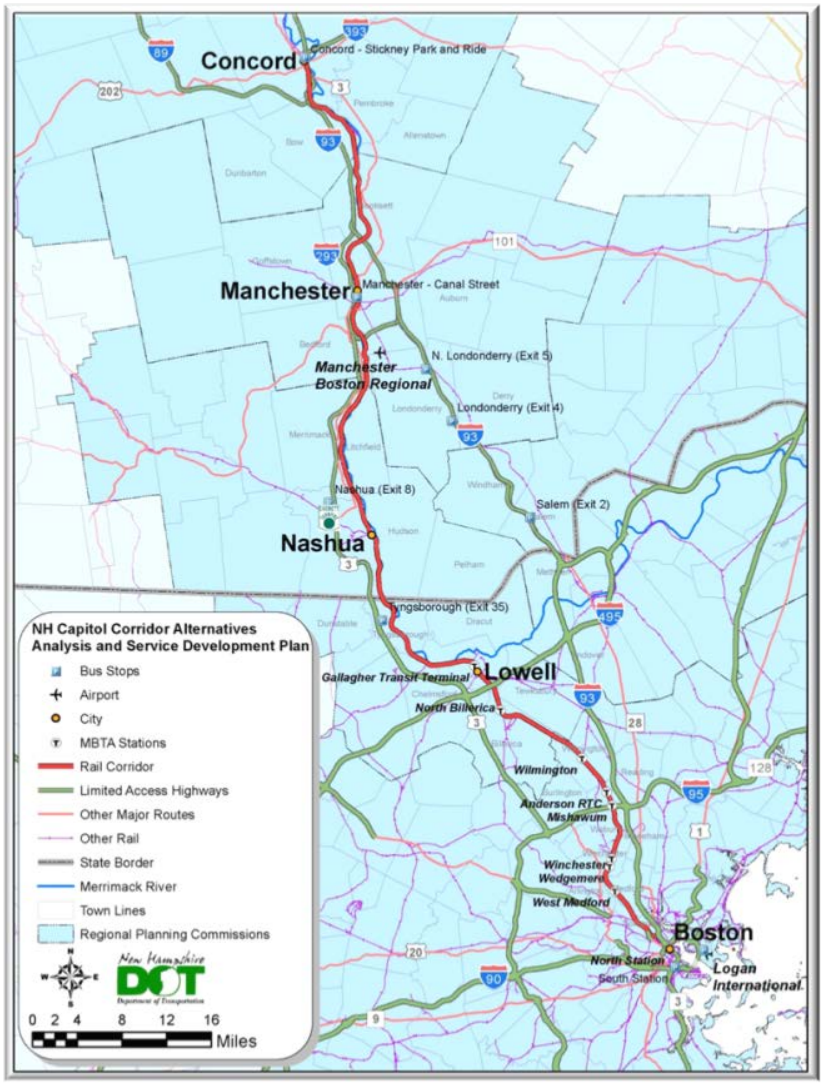
- Build support for the AA and service development planning process among different stakeholder groups
- Encourage stakeholders to engage in the development process
- Provide clear and understandable information at each step of the process
- Document public and stakeholder opinion as part of the decision-making process

As the project moves forward, the public and stakeholders will continue to be encouraged to participate.

[2] Rounded to the nearest 100th

1 Introduction

Figure 1.1: Capitol Corridor



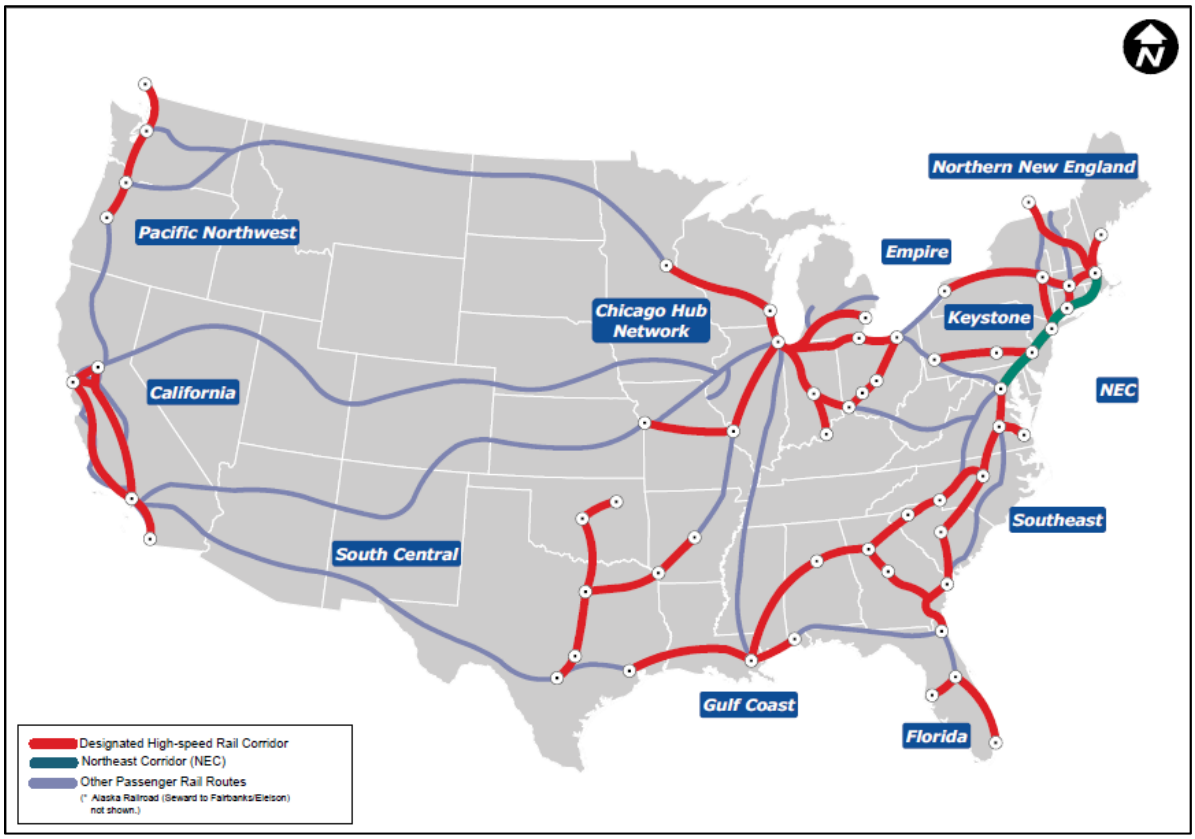
The New Hampshire Department of Transportation (NHDOT), through a funding grant from the FRA, has prepared this Service-level EA consistent with NEPA of 1969, as amended, 42 U.S.C. §§ 4321 et. seq.; its implementing regulation, 40 Code of Federal Regulations (CFR) 1500-1508; the FRA's Procedures for Considering Environmental Impacts, 64 FR 28545 (May 26, 1999); and FRA's guidance on compliance with NEPA in Implementing the High-Speed Intercity Passenger Rail (HSIPR) Program, issued August 13, 2009. The EA is also prepared in accordance with Section 106 of the National Historic Preservation Act of 1966 (NHPA), as revised in 36 CFR Part 800 (August 5, 2004). This document is subject to review and approval by the FRA.

The Capitol Corridor extends 73 miles from Boston, Massachusetts to Concord, New Hampshire. The geographic area of the corridor encompasses the existing track alignment that runs north from Boston, through Lowell, Nashua, and Manchester to Concord. The portion of the alignment within Massachusetts is owned by the Massachusetts Bay Transportation Authority (MBTA) and the portion within New Hampshire is owned by PAR. The corridor also includes US Route 3 and I-93 highway corridors, as well as Boston Logan International Airport and Manchester Airport (Figure 1.1). The corridor connects Boston with the three largest cities in New Hampshire: Concord, Manchester, and Nashua. These cities, as well as the other communities on the corridor, represent nearly 39 percent of the population and just over 41 percent of the employment in the entire State of New Hampshire. Manchester is the largest city in the northeast currently without passenger rail service.

1.1 High-Speed Intercity Passenger Rail (HSIPR) and Service-level NEPA Overview

In the *High-Speed Rail Strategic Plan*, published in April 2009, the Obama administration announced its vision for high-speed intercity passenger rail in America. The HSIPR Program was created to help address the nation's transportation challenges by making strategic investments in an efficient network of passenger rail corridors that connect communities across the country. The goal of the strategy is to (1) ensure safe and efficient transportation choices; (2) build a foundation for economic competitiveness; (3) promote energy efficiency and environmental quality; and (4) support interconnected, livable communities. The Capitol Corridor makes up a section of the larger Boston to Montreal (Northern New England) Corridor (Figure 1.2).

Figure 1.2: Designated High-Speed Rail Corridors and the Northeast Corridor



In the guidance for HSIPR, the FRA outlines two paths for complying with NEPA: Service-level NEPA and Project-level NEPA. The FRA notes that Service-level NEPA, "typically addresses the broader questions relating to the type of service(s) being proposed, including cities and stations served, route alternatives, service levels, types of operations (speed, electric, or diesel powered, etc.), ridership projections, and major infrastructure components." Project NEPA consists of a "site-specific environmental review that is appropriate to make a decision on implementing a particular project. In instances where it is fairly evident that there are likely to be significant environmental impacts, proceeding directly to prepare an EIS would be the appropriate course of action." This approach lends itself to a Tiered NEPA process,

wherein a Project NEPA (or site-specific environmental review) would be completed later in the project development process. This EA follows the Service-level NEPA process as outlined in the NEPA guidance from FRA.

This project will result in an EA that in the future may be followed by a Project NEPA EIS, EA, or CE (depending on project details and the significance of the impact). This Service-level NEPA EA addresses build and no-build alternatives for an Amtrak-operated (or similar) intercity rail service between Boston, Massachusetts and Concord, New Hampshire. The project scope (corridor-level Study), and the length of the corridor between Boston and Concord (73 miles), lends itself to the Service-level NEPA process.

1.2 Corridor History

The first passenger train in New Hampshire pulled into Nashua from Lowell, Massachusetts in October 1838.[3] Passenger rail service along this alignment was soon extended to Manchester and Concord with further extensions into the White Mountains and westerly to Hanover and White River Junction. The New Hampshire Main Line (NHML) was a principal artery of the Boston and Maine Railroad (B&M), and remains a vital portion of the PAR's network. Consequently, the line functions as a key economic link between New Hampshire and the national economy. NHML passenger service ran for almost 130 years until it was abandoned in 1967. Passenger service was briefly restored in 1980, but abandoned again when federal funding expired. Freight service has been operating continuously for 175 years.

In 2006, the Community Advisory Committee to the NHDOT Commissioner recommended expanded passenger rail as one of the five "initial action items" in its final report, a component of the state's long-range transportation plan.[4] In 2007, the New Hampshire Legislature created the New Hampshire Rail Transit Authority (NHRTA) to establish passenger rail service in New Hampshire. In 2009, the New Hampshire Climate Action Plan, prepared by the New Hampshire Climate Change Policy Task Force, recommended expanded passenger service as part of a balanced transportation system. These are examples of recent state-level recognition of the need for the Capitol Corridor Project.

1.2.1 Previous Corridor Planning

In 2003, the state DOTS from New Hampshire, Vermont, and Massachusetts commissioned a feasibility study for the Boston to Montreal rail corridor: *Boston to Montreal High-Speed Rail Planning and Feasibility Study Phase I: Final Report*. The study describes existing conditions, including those within the Boston, Massachusetts to Concord, New Hampshire portion of the Study corridor, as well as a ridership analysis of corridor stations. The study found that "further study of associated operational, engineering and cost/revenue factors is warranted," a recommendation that supports the Capitol Corridor AA Study.

[3] Crowninshield-Bradlee, Francis Boardman; *The Boston And Lowell Railroad, The Nashua And Lowell Railroad, And The Salem And Lowell Railroad (1918);* Kessinger Publishing; 2009

[4] The report of the Community Advisory Committee to the Commissioner of the New Hampshire Department of Transportation; June 9, 2006; http://www.nhcf.org/document.doc?id=34

In 2004, NHDOT developed a draft EA, *Lowell, MA to Nashua, NH Commuter Rail Extension Project Environmental Assessment (2004)*, for the corridor segment from Lowell, Massachusetts to Nashua, New Hampshire in anticipation of extending MBTA commuter rail service to New Hampshire. Because the study focuses on a segment of the Capitol Corridor Study area, its environmental analysis was used to support the Capitol Corridor AA Study.

The 2010 *New Hampshire Capitol Corridor Project Overview,* based on a white paper prepared for Amtrak,[5] details this corridor's state-of-readiness to function as part of the federal High-Speed Rail program. The overview includes many elements of the Capitol Corridor project, including proposed service, ridership forecast, capital costs, and economic impacts.

Also in 2010, NHRTA commissioned the *Economic Impact of Passenger Rail Expansion along the New Hampshire Capitol Corridor.*[6] The report assessed the economic impacts of restoring intercity passenger rail service between Boston, Massachusetts and Concord, New Hampshire. The study supports the case that the implementation of passenger rail along this corridor is a net economic benefit for New Hampshire.

In 2011, a poll was conducted by the University of New Hampshire Survey Center of New Hampshire residents to assess attitudes about the extension of commuter rail service through the New Hampshire Capitol Corridor. Findings suggest a majority of residents strongly favor extending passenger rail service in New Hampshire, and using federal funding to study the issue.

1.2.2 Other Related Planning

A number of other planning studies reference the Capitol Corridor, and are relevant to the current Study:

- The *Ten Year Transportation Improvement Plan (2013-2022)* includes a provision that requires legislative approval for capital and operating budgets associated with passenger rail service prior to expenditure.
- The *Massachusetts Department of Transportation Rail Plan (2010)* and the *New Hampshire State Rail Plan (2012)* both identify the corridor as a potential for passenger service, and the New Hampshire plan recommendations include "implement recommendations of studies of the New Hampshire Capitol Corridor."
- The *I-93 Corridor Multi-Modal Transit Investment Study (2009)* does not focus on studying the Capitol Corridor, but recognizes it as a viable candidate for passenger rail service.

[6] http://www.edrgroup.com/pdf/NH-PassRail-Economic-Impact-Memo.pdf

1.3 Corridor Existing Conditions

The Capitol Corridor's robust transportation network includes roadways, highways, transit services, intercity passenger rail service, freight railroads, airport, and pedestrian and bicyclist facilities. Despite the dense, multi-modal nature of this transportation network, demand is exceeding capacity (particularly within the highway network) and there are opportunities to improve connectivity between the current modes.

- **Highway Facilities**: The limited access highways that connect New Hampshire's major population centers to metropolitan Boston are I-93, US Route 3/Everett Turnpike, Route 128/I-95, I-293, and, I-495. Under current conditions, severe traffic congestion occurs inbound towards Boston during the weekday morning peak hour. I-93 between Route 128/I-95 and I-495 is generally over-capacity with level of service (LOS) E and F conditions. This LOS represents roadway conditions with bumper-to-bumper or completely stopped traffic. Route 128/I-95 between US Route 3 and I-93 is generally over capacity with traffic congestion. I-495 is over capacity closer to US Route 3. Near I-93, I-495 is close to and above capacity. US Route 3 operates near capacity during the weekday morning peak hour and has LOS E and F conditions between Route 128 and I-495, with congestion focused in the vicinity of the US Route 3 and I-495 interchange and the Lowell Connector. US Route 3 is close to capacity in the vicinity of North Chelmsford (Massachusetts), Tyngsborough (Massachusetts), and Nashua (New Hampshire). US Route 3 and I-93 are close to capacity in the vicinity of Manchester (New Hampshire) and Concord (New Hampshire).
- **Bus Service**: Seven regional and four local bus operators provide service within New Hampshire and intercity service to Boston and beyond. A partnership between NHDOT and Concord Coach (BX) operates roughly 50 daily bus round trips within the corridor between New Hampshire and Boston; this service typically carries 1,800 passengers per day. Existing traffic congestion along I-93 significantly impacts BX's scheduled travel times. The level of recurring daily congestion delays are built-in to the schedules. For instance, the 6:30 am southbound departure from Londonderry (Exit 4) on the I-93 service is scheduled for a one-hour trip to Boston South Station. Meanwhile, the 9:50 am southbound departure is scheduled for a two-hour and 20 minute trip, which is a built-in or induced delay of one hour and 20 minutes.
- **Commuter Rail**: On a typical weekday, Lowell is served by 44 MBTA revenue trains to and from Boston's North Station. The 25-mile trip serving up to seven intermediate station stops takes 44 to 49 minutes. Typical weekday MBTA ridership on the entire line is 17,500 passenger trips including both northbound and southbound travel. Lowell is the busiest passenger station on the line with 4,280 weekday boardings and alightings.
- **Freight Rail**: The NHML was a principal artery of B&M's (now PAR's) network and remains a key economic link between New Hampshire and the national economy. While the freight received is quite diverse, traffic flow is dominated by coal for electric generation shipped to the Bow Power Plant.

- **Airports:** Boston's Logan International Airport is currently New England's largest transportation center and ranks 20th in the nation in passenger volume. Manchester Airport ranks 140th in the nation and handled 2.814 million passengers in 2010 and remains New England's fourth largest airport by passenger volume, behind Boston Logan, Bradley International in Connecticut, and T. F. Green in Rhode Island. It contributes over $1 billion annually to the region's economy and accounts for more than 3,500 jobs in the three-county region contiguous to the airport.[7]

Once a busy main line railway, the NHML was originally double-tracked to Concord and beyond. However, today the railway is largely single-tracked north of Chelmsford with some passing sidings, yards in Nashua and Manchester, and numerous turnouts to freight customer sidings. The following provides an overview of the conditions of the existing rail line along this corridor.

- **Ownership:** In Massachusetts, the southernmost 34.5 miles of the line was acquired by the MBTA in the 1960s. In New Hampshire, the NHML is the property of PAR. PAR has conveyed trackage rights for the operation of passenger trains on the NHML northward into New Hampshire between the state line and Concord to the MBTA.
- **Railway Signal System and Traffic Regulation**: The train control signal system for the route supports Northeast Operating Rules Advisory Committee (NORAC) Rule 261 between North Station and Manchester. Rule 261 allows for bi-directional operation with automatic wayside block signals on all main line tracks. North of Manchester, there are no wayside signals and operations are governed by Data Communication System (DCS) rules, wherein a Form D train order issued over the radio by the railroad dispatcher in Billerica, Massachusetts is necessary to move a train.
- **Track Class and Speed**: Within the southern 25 miles of the NHML between Boston and Lowell, most of the trackage is rated for 60 mph passenger operations, with some segments maintained to a 70 mph speed standard, due to MBTA operations. North from Lowell is a three-mile section of track to North Chelmsford that experiences heavy freight traffic, which is maintained for a maximum freight speed of 40 mph (Class 3). North of Chelmsford the track is maintained for 40 and 30 mph freight speeds on predominately Class 3 track north to Bow and with Class 2 track north to Concord with 25 mph freight speeds.
- **Track Condition:** The track conditions along the route are consistent with the FRA Track Class and maximum speeds.
    - *Boston to Lowell:* The entire rail is welded with the latest major tie renewal completed in 1992. The oldest rail on this segment was manufactured in 1980. Much of the track uses 132-pound (per yard) rail, but approximately 20 of the 51 track miles between Boston and Lowell uses 115-pound rail.

[7] *Manchester-Boston Regional Airport Economic Impact Study*, 2008-2009, Jacobs Consultancy

  - *Lowell to Chelmsford*: The track is jointed here and the northbound track is primarily constructed with 100-pound rail manufactured in 1927. The southbound track is mostly constructed with 112-pound relay rail from 1965.
  - *North of Chelmsford*: Similar to the southern portion, the rail is almost all jointed. There are approximately two miles of welded rail just north of downtown Manchester. Nearly the entire rail is 112-pound manufactured during the first half of the 1940s.

- **Alignment**: The NHML track north of Lowell to Concord runs along the Merrimack River. This alignment has mostly gentle grades, with none steeper than 0.35 percent. The horizontal alignment curves to follow the river with few tangent (straight) segments more than one-mile long. Between Lowell and Concord, 29.6 of the 48.5 track miles are curved, 61 percent of the route. Many of the curves are sufficiently tight to impact maximum train speeds.
- **Bridges**: There are 25 bridges along the NHML between Lowell and Concord rated generally fair to good, with one bridge noted in poor condition in Tyngsborough, Massachusetts. The two longest bridges crossing the Merrimack River are not rated and should be inspected before passenger service is restored.
- **Highway Grade Crossings**: There are 35 locations identified between Lowell and Concord where roadways or pedestrian paths cross the railway at grade. Federal safety regulations require trains to sound their horns at all grade crossings. The density of 35 crossings along the 48-mile route is relatively low for a suburban railway. Of the 35 grade crossings, 21 are public roads, 13 are private drives, and one is an informal community crossing.

2 Purpose and Need

2.1 Purpose

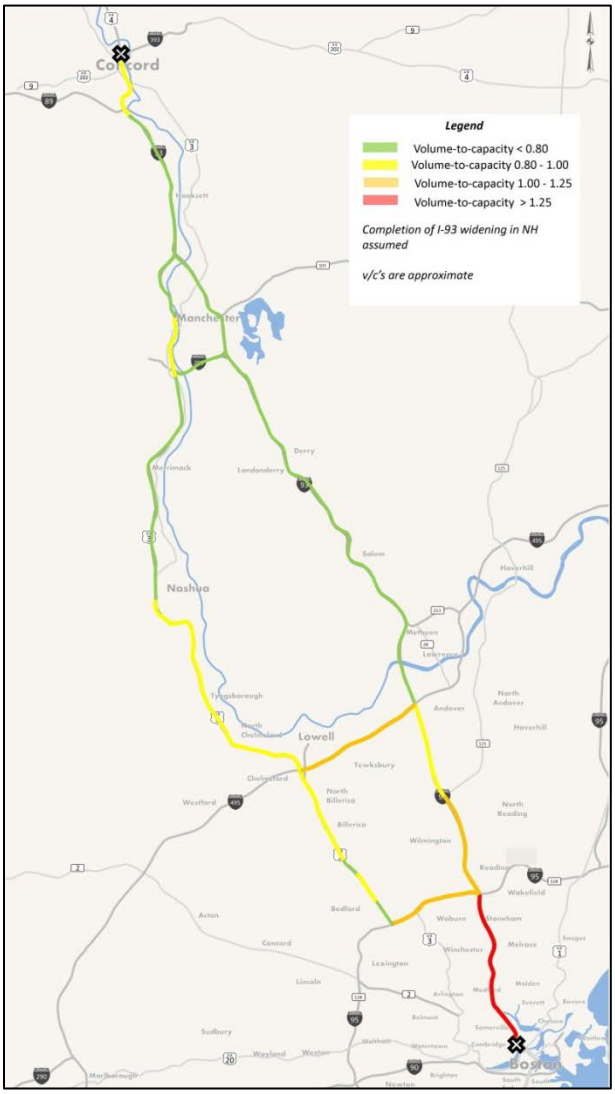
The purpose of the Capitol Corridor AA Study is to identify and implement the transit investment strategy that will best leverage the existing transportation infrastructure to improve connectivity to and from Boston, the region's largest economic hub; diversify options and reduce the primarily single-mode reliance on roadways for the movement of people and goods; support mobility options that match emerging demographic trends and preferences in the corridor; and maintain the region's high quality-of-life through strategic infrastructure investments.

2.2 Need

Projected population growth will result in increased roadway congestion. As population density increases over the coming years, an increased number of multi-modal transportation options to Boston, the region's largest employment center, will be critical to mitigate corresponding increases in roadway congestion, particularly along I-93 and Route 3, as shown in Figure 2.1.

New Hampshire's existing transportation network does not effectively connect existing modes. Increased levels of corridor transit investment will improve local and regional mobility by linking travelers to the network of existing transportation modes: roadway, buses, commuter rail, heavy rail, light rail, bicycles, and airplanes. These increased linkages will improve ridership and usage across all of the modes, while promoting sustainable mobility.

Figure 2.1: Existing Volume-to-Capacity Ratio during the Inbound Morning Peak



Regional economy suffers from predominantly singular dependency on roads for movement of goods and passengers. Investing in transportation infrastructure that provides an alternative to roadway transport will link New Hampshire's businesses, industries, and residents to the national and New England transportation network.

Improved transportation options will attract employers to New Hampshire and improve employment options for New Hampshire residents. A mismatch between locations of residence and employment forces many in New Hampshire to spend comparatively long periods of time commuting to work. Investing in more efficient transportation modes will not only improve connectivity between existing centers of residence and employment, but increased levels of multi-modal access may catalyze additional business investment within New Hampshire.

New Hampshire is experiencing a young professional "brain drain." While the region's overall population is projected to grow in the coming decades, young professionals are choosing to leave southern New Hampshire to be closer to the employment, cultural, and social opportunities that are associated with larger urban centers. Improved transit connectivity will support the attraction and retention of young professionals within the Study area.

New Hampshire is getting older. New Hampshire's senior population continues to grow. Additional shared transportation accommodations that support "car-light" mobility will be required to accommodate these emerging demographic and lifestyle trends, and will continue to make New Hampshire attractive to residents from childhood through retirement.

Residential development patterns resulting from population growth may negatively impact the region's existing quality-of-life. Population growth, if not guided through strategic infrastructure investments that promote efficiency, will result in uncoordinated development patterns and sprawl that will diminish the region's high quality-of-life and negatively impact its unique character.

The existing transportation network cannot accommodate increased levels of demand without negative environmental consequences. The expansion of existing roadways and construction of new roadways will not be sufficient to sustainably accommodate the projected growth in travel demand, causing negative environmental consequences associated with an increased number of VMT and corresponding congestion.

2.3 Goals and Objectives

To determine how well transit and/or intercity passenger rail investment within the Capitol Corridor will address regional and corridor needs, a set of goals and objectives were developed. These goals and objectives, outlined in Table 2.1, build on the work that has been completed or is ongoing within the corridor and region. Each goal reflects an understanding of the role that integrated transportation and land use planning can play in supporting an economically, environmentally, and socially sustainable community. Transit investment will be a major step in implementing this integrated planning approach within the Capitol Corridor.

Table 2.1: Capitol Corridor AA Study Goals and Objectives

Goals	Objectives
Transportation and Mobility Leverage the existing transportation network to improve access and mobility within the corridor and throughout the region	▪ Provide alternatives to address congestion within the Study corridor ▪ Expand the transit network capacity ▪ Increase transit ridership and mode share by expanding the existing rider base and attracting new riders ▪ Provide travel time savings ▪ Improve the efficiency, convenience, and reliability
System Integration Invest in transportation improvements that complement the existing multi-modal transportation network	▪ Increase corridor modal connectivity ▪ Provide connections to other corridors within the region ▪ Increase access to the Manchester Airport through additional transit service ▪ Balance system capacity (MBTA, BX, Concord Coach) ▪ Ensure operating efficiency
Economic Development and Land Use Support the vision for growth laid out in local/regional development plans	▪ Improve access to higher-paying jobs in greater Boston ▪ Support development patterns/lifestyle choices that attract younger, highly educated professionals to New Hampshire ▪ Leverage younger, highly educated employee base to attract new businesses/grow existing ones ▪ Promote Transit-Oriented Development (TOD) to mitigate sprawl development patterns ▪ Improve the potential for additional freight rail business through infrastructure upgrades
Sustainability Support transportation investments that contribute to an environmentally, economically, and socially sustainable community	▪ Leverage existing transportation infrastructure to qualify for federal transportation investment dollars ▪ Mitigate potential adverse environmental impacts resulting from anticipated development ▪ Support growth patterns that attract and retain residents from childhood through retirement ▪ Improve access to other tourism, recreation, and cultural attractions in greater Boston and NH

3 Alternatives' Evaluation

The alternatives analysis for this Study was performed in conjunction with FTA grant funding, wherein a full range of intercity, commuter rail, and bus alternatives were developed to satisfy the Study's purpose and need. Including the No Build alternative, 12 alternatives were initially screened by the Study team, with input from project stakeholders (see Appendix 4 to the Capitol Corridor AA Final Report). Three alternatives were specific to intercity passenger rail service, and of the three, one alternative was carried forward into detailed analysis (see Appendices 8 and 9 to the Capitol Corridor AA Final Report).

In addition to Service-level alternatives analysis, the Study team performed a layover facility alternatives analysis and a passenger station location alternatives analysis. The build alternative was composed of one layover facility and four passenger station locations. This analysis is detailed in Build alternative, Section 3.2.

3.1 No Build Alternative

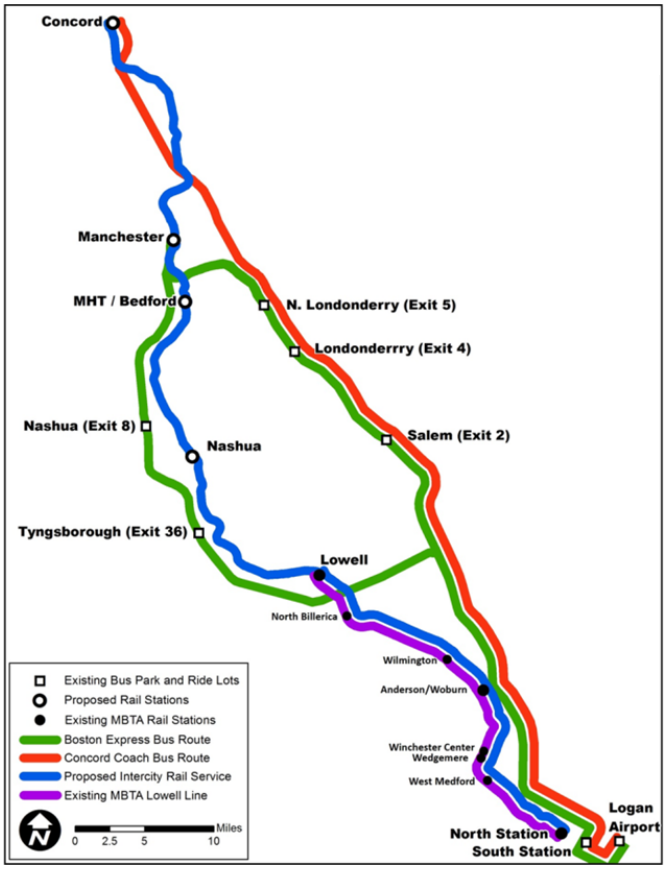
The No Build alternative is required to be evaluated under NEPA as a baseline for comparing build alternatives' impacts. Under the No Build alternative, the existing condition of the rail corridor would remain unchanged. Freight traffic would continue to serve the existing customers located on the NHML, and intercity bus service would continue to serve passengers between Concord, Manchester, Nashua, and Boston. It is assumed that population growth in the region and the demand for jobs in the greater Boston market would further negatively impact corridor traffic conditions.

The No Build alternative does not satisfy the project's purpose and need for several reasons:

- It fails to improve connectivity to and from Boston, the region's largest economic hub
- It maintains single-mode reliance on roadways for the movement of people and goods
- It does not increase mobility options that match emerging demographic trends and preferences in the corridor
- The region's high quality-of-life may deteriorate without strategic infrastructure investments

3.2 Build Alternative

Figure 3.1: Intercity Rail Service Options



Of the three intercity alternatives considered during preliminary screening, the Intercity 8 alternative was carried forward into detailed analysis. The alternatives dismissed from analysis are described briefly in Section 3.4. Intercity 8 would operate eight trips per day between Boston North Station and Concord. The four daily round trips over the 73-mile route would stop at five intermediate stations (Manchester, Bedford/Manchester Airport, Nashua, Lowell and Woburn) as shown in Figure 3.1. The end-to-end trip time would be approximately 96 minutes.

The service could be extended with possible connections to private bus services for North Country destinations. No changes are proposed to express bus service for commuting to Boston via I-93 or Route 3. Local bus service to the intercity rail stations could be offered, but would not be integral to the service design. A BX/Concord Coach/Intercity Rail fare integration scheme similar to that employed by the *Downeaster* at Portland, Maine could be employed at the Concord and Manchester stations that would be shared by both intercity rail and coach bus services.

Anticipated ridership would include new riders attracted to the intercity rail service. It is assumed that few current MBTA passengers living in New Hampshire would shift from using the MBTA Lowell and North Billerica Stations to the new intercity rail service. Some BX and Concord Coach customers might shift to intercity rail service from Nashua, Manchester, and Concord. The overall increase in the quality and frequency of transit options to Manchester and Concord may also stimulate bus ridership as has seemed to be the case at the shared terminal in Portland, Maine. Ridership figures show that Concord Coach served 216,000 passengers in Portland in 2003 while the *Downeaster* carried 250,000 passengers. In 2008, those numbers had increased to 400,000 passengers on Concord Coach and 320,000 passengers on the *Downeaster*.

The remainder of the section is focused on describing pertinent elements of Intercity 8.

3.2.1 Route

The Intercity 8 route utilizes the existing rail line from Boston to Concord that goes through Lowell, Nashua, Manchester, and Concord. Existing commuter rail service runs from Boston to Lowell, and existing freight service runs the entire length of the line.

3.2.2 Stations and Layover Facility

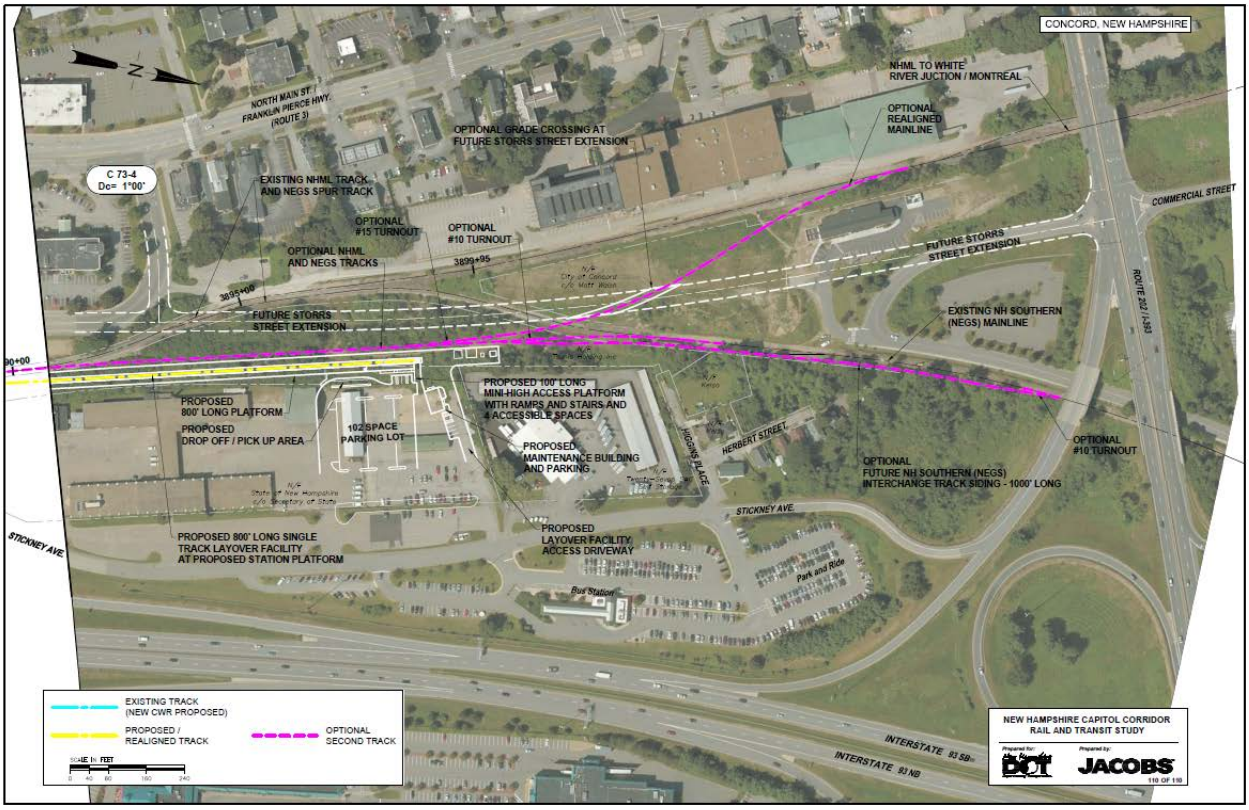
The corridor connects the two state capitals (Concord and Boston) and the two major population centers in each state (Manchester and Boston). Intercity 8 would make four stops in New Hampshire (Concord, Manchester, Bedford/Manchester Airport, Nashua), in addition to three existing Massachusetts commuter rail stops (Lowell, Woburn, and Boston). Four new passenger stations would be constructed. They would be a mix of high- and low-level platforms with "mini-high" platforms based on MBTA design standards for handicapped accessibility. High-level platforms would be preferred at all locations. A low-level with mini-high platform approach would be employed where no path was available for PAR freight trains to avoid using the platform track to ensure a clear route for wide freight loads.

The station alternatives analysis considered a wide-range of alternatives at each location. The station alternatives were determined based on field inspections, interviews with local officials, and review of previous studies. Preferred locations were then chosen through coordination with local officials and a screening process that took into account standard criteria for each alternative. Following is a summary of preferred station locations.

Concord – Stickney Avenue

The preferred station location in the City of Concord is located at Stickney Avenue, the location of the existing bus depot and park-and-ride facility (see Figure 3.2). It is also the former NHDOT headquarters, and the State of New Hampshire owns a number of parcels in the vicinity of the rail line. This site is highly rated as it could hold both a station and layover yard. The station would have one platform serving one or two tracks and operate as a joint station/layover facility. Current requirements call for only one track, but with future expansion of intercity service, two storage tracks may eventually be required. A layover yard would be required at or near the terminus of the proposed Intercity 8 rail service option. The preliminary station design shows ample land within the larger site for construction of a railway station with parking, train layover on the station tracks or on an adjacent track and New England Southern Railroad (NEGS) run around track. This design would still allow for the City of Concord's redevelopment plans and the Boston-Concord project for I-93 improvements to proceed.

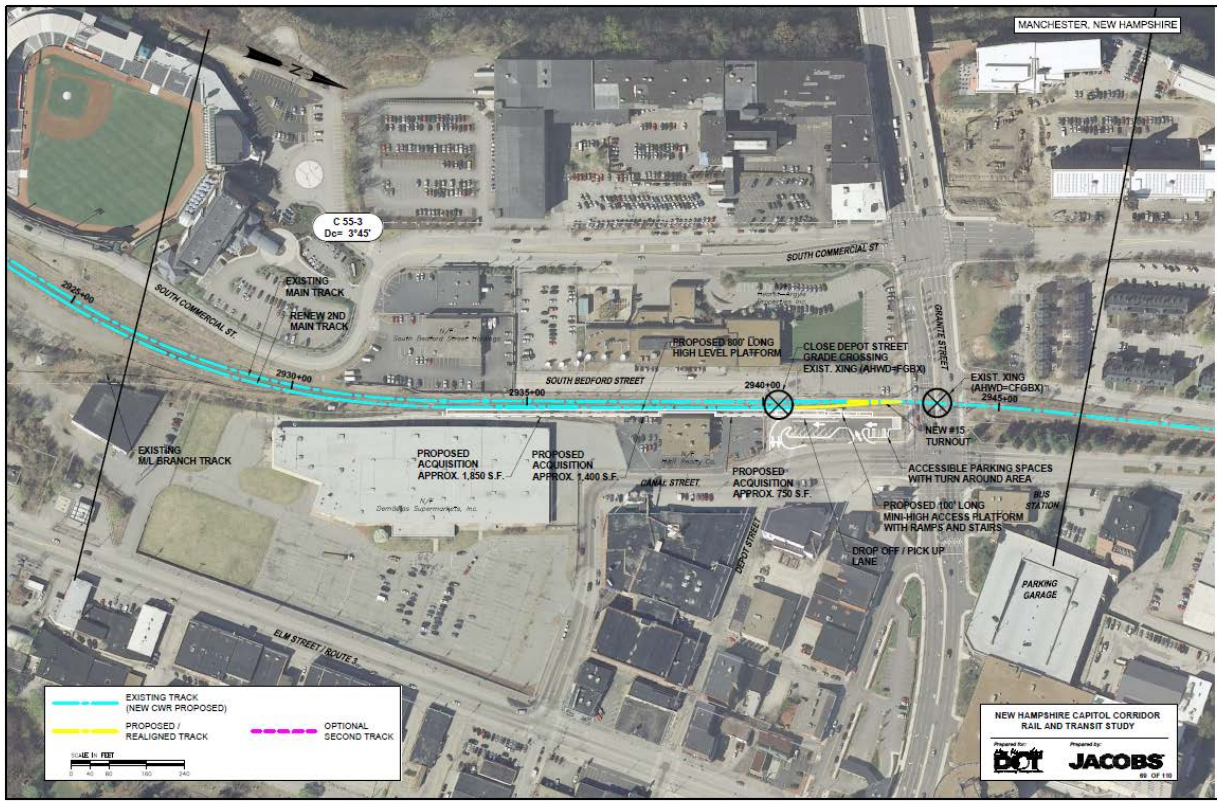
Figure 3.2: Proposed Concord Stickney Avenue Station



Manchester – Granite Street

Manchester's main passenger rail station stood for many decades on the south side of Granite Street before the building was demolished and the site redeveloped. The site is proximate to the center of Manchester's densest urban development, across the street from the intercity bus terminal, and a short walk to the Manchester Transit Authority's downtown hub at Veteran's Park (see Figure 3.3). The recommended station design would close the Depot Street crossing and develop the city-owned parcel on the corner of Granite and Canal Streets presently used for public parking. A two-track station option has been developed with a single low-level and mini-high platform serving the east track. This would enable efficient operation of a terminal station and allow for unimpeded freight traffic to and from the north.

Figure 3.3 Proposed Manchester Station



Bedford/Manchester Airport

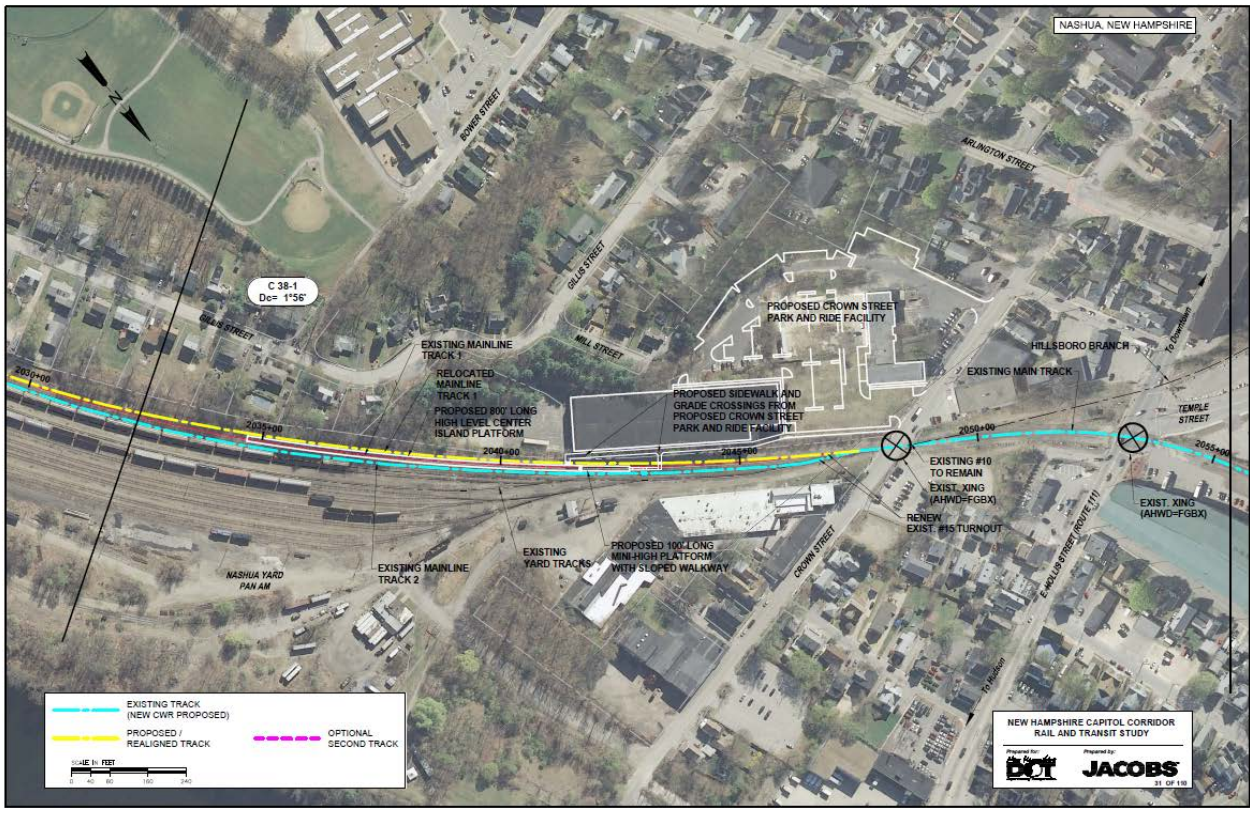
The proposed Manchester Airport station in Bedford would provide a location for air-rail passenger interchange and also serve as a regional park-and-ride for northern Hillsborough and southern Merrimack counties. The site is located under the Ray Wieczorek Drive/Pearl Harbor Memorial Bridge that provides a direct connection between Route 3 and Manchester Airport. This site has also been proposed as a development node within the Town of Bedford. A proposed shuttle bus would provide connecting service, meeting all trains, along the 2.8-mile (six-minute) route between the airport passenger terminal and the proposed station (see Figure 3.4). Similar air-rail shuttle connections are used at airports in Baltimore, Boston, and Milwaukee. The station parking lot would be managed to prohibit overnight parking, avoid use by air passengers, and keep spaces available for rail commuters from Manchester, Bedford, and other nearby communities.

Figure 3.4: Proposed Bedford/Manchester Airport Station

Nashua – Crown Street

This site is located south of Crown Street site and north and west of the PAR yard, as shown on Figure 3.5. It is the approximate location of Nashua's historic main line train station and is the only viable site near downtown that can accommodate platform requirements. The proposed 800-foot long center-island, high-level station platform would be located adjacent to the Triangle Pacific building, which could potentially be redeveloped. The city and state recently cooperated to acquire the site with the intention of developing a park-and-ride lot independent of the proposed rail service. City plans call for 255 parking spaces and reuse of existing industrial buildings. Additional parking supply would be constrained by the size of the parcel. Since this location would rely on pedestrian and bicycle accessibility, a new sidewalk would be necessary on the south side of Crown Street and east of Arlington Street to ensure safe access to the site. A pedestrian/bicycle connection off Harvard Street would provide improved accessibility from the surrounding neighborhoods.

Figure 3.5: Proposed Nashua Station



Massachusetts Stations

The train would make three stops in Massachusetts at existing transit stations:

- **Gallagher Intermodal Transit Center located in Lowell, Massachusetts**: The current terminus of MBTA's Lowell Commuter Line, with connections to local bus and intercity bus service
- **Anderson Regional Transportation Center located in Woburn, Massachusetts:** Services MBTA's Lowell Commuter Line, the Amtrak *Downeaster*, as well as a regional shuttle
- **North Station located in Boston Massachusetts:** The terminus for Amtrak's *Downeaster* and the four northern MBTA Commuter Rail Lines, and also provides connections to local buses and the MBTA subway

3.3 Train Service Levels

Four round trips per day are proposed for Intercity 8. Table 3.1 shows the proposed service schedule. This LOS mimics the LOS first used on the *Downeaster*, a model for the proposed project. Intercity 8 would not preclude a commuter rail service to either Nashua or Manchester along the same alignment.

Table 3.1: Proposed Service Schedule

380	382	384	386		Station	MP		381	383	385	387
6:38am	10:38am	2:53pm	7:53pm	Read Down	**Concord NH**	73.3		10:07am	2:22pm	6:57pm	11:37pm
6:52	10:52	3:07	8:07		**Manchester NH**	55.7		9:41	1:56	6:31	11:11
7:05	11:05	3:20	8:20		**Bedford/MHT**	50.1		9:33	1:48	6:23	11:03
7:18	11:18	3:33	8:33		**Nashua**	39.0		9:20	1:35	6:10	10:50
7:36	11:36	3:51	8:51		**Lowell**	25.5		9:02	1:17	5:52	10:32
7:52	11:52	4:07	9:07		**Anderson/Woburn**	12.6	Read Up	8:46	1:01	5:36	10:16
8:15	12:15	4:30	9:30		**North Station**	0.0		8:30	12:45	5:20	10:00

3.3.1 Train Operating Speeds

The maximum speed of the train is dependent on existing track characteristics and the amount of investment required to increase the speeds in the corridor. The maximum historic passenger speed along the NHML was 70 mph. The NHML track profile or vertical alignment north of Lowell to Concord runs along the banks of the Merrimack River. Many of the curves are sufficiently tight to impact maximum train speeds. The engineering required to achieve trains speeds of 80 mph or higher is substantially more challenging with sharp curves. Between Lowell and Concord there are 19.6 miles of such restrictive curves that constitute 40 percent of the route miles. As such, the service would operate at maximum speeds up to 75 mph between the Manchester Airport and Nashua and 70 mph at many other locations.

3.3.2 Ridership Projections

All ridership estimates presented in this chapter are station boardings. It is expected that travel patterns would be symmetrical and each station would have an equal number of alightings, thus total system ridership is two times the estimated boardings. The estimates are all present-day forecasts and do not assume any changes in regional socioeconomics, travel demand, or auto congestion. Ridership estimates for Intercity 8 are based on the Fiscal Year 2013 Amtrak *Downeaster* ridership/revenue data and are presented in Table 3.2. Each station on the proposed service is associated with a *Downeaster* "surrogate" station with similar travel time, station demographics, and train service characteristics.

Table 3.2: Ridership Demand Forecast (Start of Service)

Station	Annual Average Boardings	Average Daily Boardings
Concord	28,470	78
Manchester	67,890	186
Bedford/MHT	28,105	77
Nashua	48,180	132
Total	**172,645**	**473**

3.3.3 Major Infrastructure Components

Historically the NHML had two tracks along the entire length between Boston and Concord. Today, aside from sidings, the rail line is single-tracked north of Chelmsford. To balance the need to achieve maximum allowable speed with an acceptable level of capital and operating expense, it was decided that the existing rail would be upgraded, and enough second track would be provided to accommodate both passenger rail and freight on the same line. As such, double track will not need to be installed throughout the corridor.

No improvements south of MBTA's Lowell Gallagher Terminal would be required. North of Lowell the railroad would be upgraded to permit safe, reliable operation of eight daily passenger trains at speeds of up to 75 mph. Recommended upgrades to track, bridges, crossings, and signals are summarized below.

- **Track:** All of the existing 70-plus-year-old 112-pound main line rail between Lowell and Concord would be upgraded with new continuous welded rail (CWR) of a similar weight. Along segments where the rail is renewed with CWR, approximately one-third of the existing ties would be replaced. No double track would be required between North Chelmsford (MP 28.5) and the southern end of the Tyngsborough Curve (MP 32). Industrial sidings would be created at three key areas of freight activity in Nashua and Merrimack to eliminate conflicts between local freight deliveries and through passenger trains. At these locations the existing main line track would be retained as an industrial siding with an entirely new parallel main line track constructed in the same alignment for use by through trains. Adding a second track would be straightforward, as the railway was once entirely double-tracked with the double-track bed still largely intact.
- **Bridges:** The service expansion would use 25 existing bridges over watercourses or roadways. Most of the bridges are rated as having sufficient strength to accommodate the proposed additional traffic. One bridge in Tyngsborough is a candidate for complete replacement. The large steel (circa 1930) structure spanning the Merrimack River between Manchester and Bedford is subject to more detailed inspection. In Hooksett, the 488-foot steel bridge also spanning the Merrimack is similarly subject to more detailed inspection. The other 22 bridges should receive a renewal of worn and weakened components when the rails crossing them are replaced.
- **Grade Crossings:** With double tracking and increased frequency of faster trains, most of the 35 roadway grade crossings between Concord and downtown Lowell would need upgrades in their AHWD. The density of crossings just north of the proposed Granite Street Station in Manchester is especially high.
- **Other:** Upgrades to the train control and signal systems would also be required as well as some new switches and reconfigurations of track.

3.4 Alternatives Considered

During the alternatives development process, the Study team considered a wide-range of alternatives. This section provides an overview of the development process and justification for dismissal.

3.4.1 Route Alternatives

The travel corridor encompasses Route 3, I-93, and the existing rail lines that historically ran between New Hampshire and Massachusetts. A previous study, *I-93 Corridor Multi-Modal Transit Investment Study*, completed in 2009 by NHDOT, evaluated each of these corridors and the feasibility of utilizing the corridors for transit investments. For rail alternatives, the study analyzed the NHML, which is the preferred route alternative for this Study, the old Manchester & Lawrence (M&L) Branch, which extends north from Lawrence off of the existing MBTA Haverhill line, and, lastly, the I-93 Corridor, which can accommodate a new rail line within the existing right-of-way. The M&L Branch and I-93 corridor alternatives were dismissed for this Study for similar reasons – each line would require either extensive rail upgrades, or in some cases entirely new rail infrastructure to accommodate future rail use. The NHML is the only corridor that has intact and maintained rail infrastructure along its entire length, and as such, was chosen as the Intercity 8.

3.4.2 Station Alternatives

The station alternatives were determined based on field inspections, interviews with local officials, and review of previous studies. The preferred locations described above were then chosen through coordination with local officials and a screening process that took into account standard criteria for each alternative. If the Intercity 8 progresses to the next phase, additional development information may become available that could alter station location alternatives. The following is a summary of the stations that were analyzed, but dismissed from detailed analysis at this time.

- **Concord:** In addition to the Stickney Avenue site, the Study team analyzed a site at the base of Depot Street, which was the historic site of Concord's rail station. The original station was torn down in 1960, and the existing land use at the site is commercial and retail, with private ownership. Because the existing land use was incompatible with the proposed station, and a more feasible alternative consistent with Concord downtown development plans was available, this alternative was dismissed from analysis.
- **Manchester:** In addition to the Granite Street site, the Study team analyzed two additional sites: (1) at the base of Spring Street and underneath the overpass for West Bridge Street and (2) in the gaslight district near the location of the existing Market Basket supermarket. Of the three alternatives analyzed, the Granite Street location best fit the Study purpose and need due to its close proximity to the bus depot and existing development in the city. As mentioned above, if future development plans emerge in the next project phase, they could alter the preferred station location for Manchester.
- **Nashua:** In addition to the Crown Street site, the Study team analyzed three additional sites: (1) Beazer East property north of downtown adjacent to Greeley Park, (2) Dow Chemical property at the base of Spit Brook Road, and (3) adjacent to the Pheasant Lane Mall. The Beazer East property was the least desirable site as it was located furthest from the highest density development in the city and was the least accessible location. The two additional sites were developed as commuter rail station alternatives. For Intercity 8, it was determined one station

location would serve the City of Nashua to best balance demand and schedule efficiencies. Under this scenario, the Crown Street site best fit the Study purpose and need.

3.4.3 Train Service Levels

Three service-level alternatives were initially developed. In addition to the four round trips per day on the Intercity 8, the Study team analyzed six round trips per day and nine round trips per day. The main difference between the alternatives was operations cost, as the six and nine round trip alternatives would require an additional train set to accommodate this LOS. The four-round-trips-per-day alternative are the same as the level of service the *Downeaster* used at the beginning of its operation. Based on the *Downeaster's* success, it was determined that the four-round-trips-per-day alternative was the most feasible service level that was still able to satisfy the project Study and need.

3.4.4 Ridership Projections

The Study team developed preliminary ridership projections for the additional two service levels. Since the four-round-trips-per-day alternative was selected for detailed analysis, it was the only alternative that received detailed ridership projections.

4 Affected Environment and Environmental Impacts

This section describes potential impacts resulting from construction and operation of Intercity 8 for the following resources: Air Quality, Noise and Vibration, Hazardous Waste Sites, Water Quality, Wetlands, Threatened and Endangered Species, Floodplains, Energy Resources, Visual Resources, Accessibility, Property Acquisition, Land Use, Environmental Justice, Public Safety, Cultural Resources, Park and Recreations, Socioeconomics, Transportation, and Indirect Effects and Cumulative Impacts. Impacts were identified and assessed with regard to the anticipated level of intensity based on a review of scientific literature, previously prepared documentation, and the professional judgment of resource specialists.

Potential impacts are described in terms of the following:

- **Type**: Beneficial impact (a positive change in condition of the resource) or adverse impact (a change that reduces or degrades the condition of the resource)
- **Context**: Local, regional, global, or any combination
- **Duration**: Short- or long-term

4.1 Air Quality

The Capitol Corridor Air Quality and Global Climate Change Study follows the Service-level NEPA process as outlined in the HSIPR NEPA guidance from FRA. The Study and related analyses looked at the following pollutants: ozone (O_3), particulate matter (PM), including PM_{10}, (10 micrometers or less in diameter and PM 2.5, 2.5 micrometers or less in diameter), carbon monoxide (CO), nitrogen oxide (NO_x),

sulfur dioxide (SO_2), lead, asbestos, and mobile source air toxics (MSAT). In addition, greenhouse gases (GHGs), including carbon dioxide, methane, nitrous oxide, and synthetic GHGs, were analyzed for climate change impacts.

40 CFR Part 51, Subpart W, applies in states where the state has an approved State Implementation Plan (SIP) revision adopting General Conformity regulations. 40 CFR Part 93, Subpart B, applies in states where the state does not have an approved SIP revision adopting General Conformity regulations. The project is subject to the general conformity regulations, but not the transportation conformity guidelines in 40 CFR Part 93.109 and 93.119.

On a local scale, the potential effect of the Intercity 8 alternative on air quality is limited to increases in locomotive emissions, and both increases and decreases in on-road emissions. Decreases in on-road emissions could have a beneficial impact on local air quality if large numbers of vehicle trips are shifted to rail, occurring along roadways where those trips would otherwise occur. Since the details of that shift are not clearly known at this time, this potential benefit has not been analyzed; however, a more meaningful analysis of the region-wide benefits of this mode shift is included in the regional analysis.

For local impacts, CO hotspot and PM hotspot analysis were not conducted because this is a Tier I document (this would be performed during the project's next phase), but locomotive emissions factors were obtained from "2009 Technical Highlights for Locomotive Emissions" by the U.S. Environmental Protection Agency (USEPA). The total emissions were distributed to each state (Massachusetts and New Hampshire) and by attainment areas. For regional impact, the locomotive emission factors used are the same as for the local impact. An on-road vehicle emission analysis was conducted using average daily VMT estimates and associated average daily speed estimates for each of the affected areas. The criteria pollutants emissions for the vehicles were obtained from USEPA Motor Vehicle Emission Simulator (MOVES) model (national level allocated to the Hillsborough and Merrimack counties in New Hampshire). Total VMT were obtained from the project traffic study. The analysis was conducted for the modeling year 2020. To determine overall pollutant burdens generated by on-road vehicles, estimated VMT increases or decreases were multiplied by applicable pollutants' emission factors, which are based on national default speeds and vehicle speciation data, and using a 2020 analysis year.

Based on the Federal Highway Administration (FHWA) guidance, Intercity 8 does not require a detailed quantitative analysis for MSAT. In addition, the detailed project level MSAT and GHG emission factors for vehicles and locomotives are not available in the current version of MOVES. Therefore, the hazardous air pollutant and GHG emissions were estimated by scaling either NO_x emissions from the MOVES model, SO_2 emissions from locomotive engines, or NO_x emissions from USEPA's 2011 National Emissions Inventory data. The Air Quality Technical Memorandum in Appendix A to this EA has the detailed methodology and the results.

4.1.1 Affected Environment

Ambient air quality standards have been set by both the federal government and state agencies. Both New Hampshire and Massachusetts do not designate areas as state attainment or nonattainment with

these standards. USEPA, in response to the federal Clean Air Act (CAA) of 1970, established National Ambient Air Quality Standards (NAAQS) in Title 40 CFR Part 50. The NAAQS include both primary and secondary standards for six "criteria pollutants." These criteria pollutants are O_3, CO, nitrogen NO_2, SO_2, PM_{10}, $PM_{2.5}$, and lead. Primary standards were established to protect human health, and secondary standards were designed to protect property and natural ecosystems from the effects of air pollution. The NAAQS and related requirements can be found in the Air Quality Technical Memorandum in Appendix A.

The Study area is classified as attainment with respect to the NAAQS for O_3, NO_2, PM_{10}, $PM_{2.5}$, SO2, and CO, except for some areas in Massachusetts that are maintenance areas for CO (1971 standard) and nonattainment areas for O_3 (1997 standard). Some areas in New Hampshire are nonattainment areas for SO_2 (2010 standard) and maintenance areas for CO (1997 standard).

NO_x and SO_2 are regulated as PM_{10} precursors, and NO_x and volatile organic compounds (VOCs) as O_3 precursors. Table 4.1 provides the area, pollutant, attainment status, and the General Conformity applicable *de minimis* emission levels for the Study area.

Table 4.1: Air Pollutants and NAAQS Attainment Status

Area	Pollutant	Attainment Status	General Conformity applicable de minimis emission levels tons per year (tpy)
MA – Boston and Lowell	CO (1971 standard)	Maintenance	100
MA – Boston-Lawrence-Worcester	Ozone (1997 standard)	Nonattainment - Moderate	100 (NO_x and VOC)
NH – Hillsborough County	CO (1971 standard)	Maintenance	100
NH – Central New Hampshire	Sulfur Dioxide (2010 standard)	Nonattainment	100
NH – Boston-Manchester-Portsmouth	Ozone (1997 standard)	Maintenance	100 (NO_x and VOC)

The ambient air quality in the project area is monitored at a number of permanent air quality monitoring stations operated by USEPA, Massachusetts Department of Environmental Protection (MassDEP), and New Hampshire Department of Environmental Serves (NHDES). The monitoring stations within Massachusetts that are closest to the project area are in Chelmsford, Lawrence, and Boston (Charlestown, North End, Kenmore Square, and Roxbury). In New Hampshire, the monitoring stations nearest to the project area are in Nashua (Gilson Road and Crown Street), Concord, Peterborough, and Manchester. For each pollutant, the maximum concentration from these stations was selected as a conservative background. These numbers can be found in the Air Quality Technical Memorandum in Appendix A.

Hazardous Air Pollutant Emissions: The federal CAA Amendments of 1990 listed 188 Hazardous Air Pollutants (HAPs) and addressed the need to control toxic emissions from transportation. USEPA's 2007 MSAT rule identified a subset of seven HAPs as having significant contributions from mobile sources:

benzene, 1,3-butadiene, formaldehyde, acrolein, naphthalene, polycyclic organic matter (POM), and diesel particulate matter (DPM).

Greenhouse Gas Emissions: Climate change and GHG emission reductions are a concern at the federal level. Laws and regulations, as well as plans and policies, address global climate change issues. This section summarizes key federal regulations relevant to the project.

In Massachusetts v. U.S. Environmental Protection Agency, et al., 549 U.S. 497 (2007), the United States Supreme Court ruled that GHG does fit within the CAA definition of a pollutant and that USEPA has the authority to regulate GHG.

On February 18, 2010, the White House Council on Environmental Quality (CEQ) released draft guidance regarding the consideration of GHG in NEPA documents for federal actions. The draft guidelines include a presumptive threshold of 25,000 metric tons of carbon dioxide equivalent (CO_2e)[8] emissions from a proposed action to trigger a quantitative analysis. CEQ has not established when GHG emissions are significant for NEPA purposes (CEQ 2010); therefore, there is no standard for GHG emissions to compare for this project.

4.1.2 Intercity 8 Alternative

The mobile source dispersion models and hotspot analyses are not required for this project at a Service-level NEPA analysis, as the results of the local scale emissions for the project are below the federal general conformity *de minimis* levels for all applicable criteria pollutants in every nonattainment or maintenance area in New Hampshire and Massachusetts. Therefore, the local air quality impact is not significant due to the project operation.

For the regional context, the emission increases presented in Table 4.2 show the Intercity 8 alternative would not only be below the federal general conformity *de minimis* levels, but would also even create net emission reduction benefits by saving vehicle trips for some pollutants (CO and SO_2). Therefore, the project is presumed to conform to the applicable SIPs and would not require a full conformity analysis and conformity determination. The detailed analysis can be found in the Air Quality Technical Memorandum in Appendix A.

[8] A universal unit of measurement that allows the global warming potential of different GHGs to be compared

Table 4.2: Air Quality Impact for Intercity 8 – Criteria Pollutants

Emissions Increases (ton/year)	CO	NO_x	PM_{10}	$PM_{2.5}$	SO_2	VOC
Personal Vehicles	-29.23197	-1.91873	-0.09452	-0.08367	-0.03412	-0.69074
BX Buses	-3.80473	-13.77503	-0.62906	-0.57871	-0.02642	-0.85324
Locomotive	7.12735	47.88687	1.78184	1.72838	0.02513	2.81441
Net Emissions Increases	-25.90935	32.19311	1.05826	1.06600	-0.03540	1.27043
Applicable General Conformity Emission de minimis level (to each nonattainment or maintenance area)	100	100	NA	NA	100	100
Exceed de minimis level?	No	No	NA	NA	No	No

Note: NA = Not Applicable

The estimated annual operational emissions increases in MSAT (HAPs) and GHG emissions associated with Intercity 8 are presented in Table 4.3 and Table 4.4, respectively. The Intercity 8 alternative is expected to create less emissions in GHG by saving vehicle trips and, therefore, it would have less environmental and global climate change impact and be more beneficial to the environment.

The New Hampshire 10-year State Energy Strategy from the New Hampshire Office of Energy & Planning Department in September 2014 also supported rail as one of the major energy-saving strategies for the state. It recommended the State of New Hampshire should continue supporting efforts to maintain and to expand rail service.

Table 4.3: Air Quality Impact for the Intercity 8 Rail Alternative – Hazardous Air Pollutants

Emissions Increases (ton/year)	1,3-Butadiene	Acrolein	Formaldehyde	Benzene	Naphthalene	POM	DPM	Lead
Net Emissions Increases	0.15421	0.01502	0.33887	0.89938	0.05998	NA	1.07	0.00007

Note: NA = Not Applicable

Table 4.4: Air Quality Impact for Intercity 8 Alternative – Greenhouse Gases

Emissions Increases (metric ton/year)	Greenhouse Gases in CO_2e
Personal Vehicles	-699.40
BX Buses	-5,021.15
Locomotive	2,735.13
Net Emissions Increases	-2,985.41

Since global climate change is caused cumulatively by world-wide activity, the impact of a specific program on climate change cannot be determined. Therefore, the approach applied here for evaluating the potential impact of the project is to identify the project's potential GHG emissions, and to evaluate whether it incorporates cost-effective energy efficiency and renewable energy measures into its design, construction, and operation to the maximum extent practicable, consistent with social, economic, and other essential considerations. By doing so, the project would demonstrate consistency with state and local policies.

Since this is a Service-level NEPA impact analysis, the details of design, construction, and operation are not yet fully available. Therefore, this section identifies potential measures for inclusion, which would reduce the project's energy and GHG footprint if implemented. These measures will be further investigated, and, if found to be practicable, incorporated in the project's design and operation.

Operational

Shift Locomotives Engines to Higher Tier 1s or to Change the Fuel to Biodiesel Fuel: Options to use biodiesel for the locomotives could be investigated, including blends of B20 and B100 (20 percent biodiesel with 80 percent standard diesel, or pure biodiesel). B20 can be used with current technology while B100 may require some adjustments or new engines. The use of B20 would reduce GHG emissions by 10 percent and B100 would reduce GHG emissions by 70 percent, reducing operational emissions by 2,300 to 3,000 metric tons CO_2e annually.

Electrification: The benefits of shifting rail operations along the entire line to electricity have not been quantified at this time. Benefits would increase over the years as the New Hampshire grid shifts to increasingly higher fractions of renewable power sources (the New Hampshire grid currently includes relatively large fractions of nuclear and hydro power, which result in very little GHG emissions). It is noted that the cost of electrification is not included in Intercity 8.

Sustainable Station Design and Construction: Although station energy use was not included in this analysis, new stations could be designed in accordance with the new requirements from the state.

Construction

Use of Local, Renewable, Recycled Materials: 75 percent of the construction emissions were estimated to come from the extraction, production, transport, and disposal of construction materials. Although precise details are not known at this time, reduction in these emissions can be substantial if local, renewable, and recycled materials are used. The largest contributors are cement and steel. If emissions associated with material can be cut in half (existing strategies demonstrate that this is possible), the emissions payback period could be reduced by nearly 40 percent.

Biodiesel for Construction Engines: Biodiesel blends would be used in construction engines to the extent practicable.

Replanting Trees: Although not quantified in this analysis, any trees that need to be removed for construction could be replaced with a larger number of trees, replacing the trees in kind or more on a tree-mass basis.

Future Analysis: If Intercity 8 progresses, the next level analysis would include the potential air quality implications of local traffic to and from stations, locomotives, and other sources operating in rail yards and other locations. Potential construction impacts would also be analyzed. If the project is not included in the SIP, an applicability analysis would be performed to determine whether a general conformity analysis is required. In addition, because line-haul operations change substantially, micro-scale line-haul and meso-scale emissions likely would be investigated. All emission estimations for criteria pollutants, HAPs, and GHG would need to be refined. The detailed GHG reduction measures may be reviewed and evaluated for applicability and practicability, and incorporated into the project as appropriate. In addition, beneficial measures would be quantified, if practicable. If substantial changes in design occur, the overall GHG emissions analysis would be reevaluated as well, and further refined if possible.

4.2 Noise and Vibration

The noise and vibration limits chosen for the analysis satisfy the federal guidelines of the FTA for train and rail facility operations.[9] The noise-sensitive receptors for the analysis include relevant receptors defined by FTA criteria. The number of receptors potentially impacted have been determined using FTA's general assessment guidelines, including comparing existing with future noise levels and rating impacts. The vibration impact assessment uses the FTA general assessment procedure of determining whether absolute vibration limits will exceed specified thresholds at vibration-sensitive receptors. Additional detail can be found in the Noise and Vibration Technical Memorandum in Appendix B.

4.2.1 Affected Environment

The region for this analysis includes areas and communities within Middlesex County in Massachusetts and Hillsborough and Merrimack Counties in New Hampshire. These areas are mixed in terms of rural, residential, commercial, and industrial with isolated residential clusters considered to be suburban in nature, except for the downtown urban areas of Lowell, Nashua, Manchester, and Concord.

In general, freight trains without horns would generate 67 decibels (dBA) day-night average noise levels (L_{dn}) at 50 feet from the rail tracks. The noise level would drop off at a rate of 4.5 dBA per doubling of distance, per the FTA Guidance Manual. The warning horn noise level would be 74 dBA L_{dn} at 50 feet from the rail centerline within one-fourth-mile of each grade crossing.

Warning horns would be the dominant noise sources when receptors are near grade crossings. When receptors are not near grade crossings, the dominant noise sources would be passing freight trains, passenger trains, or vehicular traffic.

[9] FTA. *Transit Noise and Vibration Impact Assessment*. USDOT Report Number FTA-VA-90-1003-06, May 2006

4.2.2 Intercity 8 Alternative

Intercity 8 was analyzed for impacts to noise and vibration related to operations, stations, traffic, and construction.

Operations Noise Impacts: Intercity 8 would have predicted unmitigated noise impacts due exclusively to the added warning horns. Table 4.5 provides a summary of the unmitigated noise impact results. Hillsborough County, New Hampshire has the most parcels with severe noise impacts with 58 single-family residential units and 13 multi-family residential units impacted. Installation of stationary wayside horns at the grade crossings where severe, unmitigated noise impacts exist for Intercity 8 would mitigate noise and result in no adverse noise impact on the surrounding communities.

Table 4.5: Summary of Unmitigated Noise Impact Results

County	Number of Severe Impact Parcels				Number of Moderate Impact Parcels			
	Residential Single-Family	Residential Multi-Family	Institutional	Recreational	Residential Single-Family	Residential Multi-Family	Institutional	Recreational
Middlesex (MA)	2	0	0	0	47	50	1	1
Hillsborough (NH)	58	13	0	0	503	46	0	0
Merrimack (NH)	2	0	0	0	54	5	0	0

Source: URS Corporation, 2014

Operations Vibrations Impacts: Due to the distance between the rail activities and the closest vibration-sensitive locations, no vibration-related impacts are anticipated with Intercity 8. None of the residential buildings in the Study area would experience levels exceeding the FTA limits of 80 Vibration Velocity Level (VdB) for ground borne vibration and 43 dBA for ground-borne noise. Likewise, no institutional buildings in the Study area would experience levels exceeding the FTA limits of 83 VdB and 48 dBA.

Station Noise Impacts: The dominant noise source near each station would be the warning horn. When a train slows down near a station, train pass-by noise would be reduced. However, the warning horn would be used when a train approaches each station regardless of the train speed. There are no noise- or vibration-sensitive parcels within 500 feet of any of the proposed station sites to be impacted by the station noise, including horn soundings. Therefore, station noise is considered negligible and not included in the impact calculation.

Traffic Noise Impacts: While traffic conditions would change for the roadways around the proposed stations, there are no new major roadways or roadway expansions anticipated Intercity 8. Because the proposed stations are located in the developed areas of Nashua, Bedford, Manchester, and Concord, the existing traffic volumes around the station sites are already high. Traffic noise produced by Intercity 8 is not anticipated to cause significant impacts due to the already existing high-ambient noise environment and lack of sensitive receptors in the impact range of Intercity 8.

Construction Noise Impacts: Only four potential daytime impacts and up to 324 potential nighttime impacts have been identified as a result of the analysis. However, any such impact would be addressed through committed mitigation measures. Because the construction noise mitigation measures would be followed during construction, no noise impacts would result from implementing Intercity 8. Table 4.6 provides a summary of the unmitigated construction noise impact results.

Table 4.6: Summary of Unmitigated Construction Noise Impact Results

County	Potential Daytime Impacts				Potential Nighttime Impacts			
	Residential Single-Family	Residential Multi-Family	Institutional	Recreational	Residential Single-Family	Residential Multi-Family	Institutional	Recreational
Middlesex (MA)	0	1	0	0	27	43	2	2
Hillsborough (NH)	3	0	0	0	205	29	0	1
Merrimack (NH)	0	0	0	0	11	2	1	1

Source: URS Corporation, 2014

Construction Vibration Impacts: Intercity 8 is not expected to result in impacts exceeding FTA limits for residential buildings or for institutional buildings in the Study area. There are no significant vibration impacts expected from Intercity 8 construction. Some equipment may cause perceptible ground-borne vibrations. For example, construction equipment can produce vibration levels at 25 feet that range from 58 VdB for a small bulldozer to 112 VdB for heavier equipment. Any potential impacts would be mitigated during construction.

4.3 Hazardous Waste Sites

The NHDES OneStop Geographic Information System (GIS) website was used to identify contaminated sites within the 1,000-foot search distance. The website includes NHDES project sites with administrative tracking records, such as underground storage tanks (USTs) and hazardous waste generators, as well as contaminated sites with documented discharges or suspected discharges of petroleum or hazardous materials. In reviewing the corridor through the OneStop GIS website, three basic assumptions were applied: 1) the Merrimack River is considered to be a contaminant migration barrier -soil and groundwater contamination are assumed to not cross the river, 2) groundwater flow within 1,000 feet of the Merrimack River is generally toward the river, and 3) sites with a status of Closed or Inactive are assumed, in the absence of other mitigating factors or information, to be in compliance with state and federal requirements with respect to soil and groundwater.

A database report was commissioned from Environmental Data Resources, Inc. (EDR) for each of the properties proposed for construction of new facilities (Target Properties). The EDR report includes a summary of environmentally-related sites identified in state and federal environmental databases (database sites). These sources include databases that track controlled facilities and/or activities, e.g., hazardous waste generators and regulated USTs with no identified violations, as well as sites with

known contamination such as discharges of petroleum and/or hazardous waste, remediation activities, institutional controls as the result of discharges, and ongoing environmental monitoring due to discharges. The search radius of the database report for each Target Property conforms to the American Society for Testing Materials (ASTM) 1527-13, Section 8.2.1, and is based on the approximate property or construction boundaries.

Additional details are in the Contamination Inventory Memorandum in Appendix C to this report.

4.3.1 Affected Environment

Along the existing railroad track bed, there is a high probability of the presence of contaminated soils or debris. Contaminants commonly found associated with railroad corridors include railroad ties (wood treating chemicals), spilled, or leaked fluids (oil, cleaning solvents), herbicides, transformer fluids [Polychlorinated Biphenyls (PCBs)], fossil fuel combustion products [Polycyclic Aromatic Hydrocarbons (PAHs)], asbestos, and metals such as arsenic and mercury. Also, existing steel bridge overpasses along the corridor were likely painted with lead-based paint prior to 1970, which may or may not have been removed or sealed.

Full Corridor: Of the contaminated sites within 1,000 feet of the corridor, 81 were identified as having the potential to impact the corridor.

Concord – Stickney Avenue: The Target Property has a history as a vehicle repair and machine shop facilities since at least 1926. Sign and highway department equipment painting has been conducted on the property during the prior NHDOT usage and vehicle painting continues currently as a commercial operation. Based on the development history, the presence of petroleum and halogenated VOCs, PAHs related to coal use in the past, hazardous materials related to painting and solvent usage, and elevated metals concentrations in the subsurface is possible.

Manchester – Granite Street: The EDR database report did not identify the Target Property as a contaminated site. The property is depicted on historical Sanborn maps dated 1885 and 1891 as rail tracks and a freight depot. An 1897 map depicts tracks only. The 1915 through 1954 maps depict rail tracks and a rail station and associated facilities. The 1971 and 1983 maps depict rail tracks and parking; the 1985 and 1989 maps depict rail tracks and a commercial building on the southern portion and parking. The building is currently occupied by Hampshire First Bank with an address of 80 Canal Street.

Bedford/Manchester Airport: The EDR database report did not identify the Target Property as a contaminated site. The Target Property is not depicted on historical Sanborn fire insurance maps. Historical aerial photographs appear to depict the Target Property as undeveloped from 1947 through 1998. No contaminated sites requiring further review were identified.

Nashua – Crown Street: The Target Property and vicinity has been developed for industrial use since prior to circa 1885, as documented by historical Sanborn fire insurance maps. Documented property usage nearby has included machine shops, a steam boiler works, and rail. The OneStop database indicates that the site is a Leaking Underground Storage Tanks (LUSTs), Unsolicited Site Assessment, and

a Brownfields site. A Phase I/II report has been completed for the property on behalf of the City of Nashua.

4.3.2 Intercity 8 Alternative

Intercity 8 may have short-term, adverse impacts during construction of the rail and station sites due to the potential for movement of contaminated soils or material. Intercity 8 would also likely have a long-term beneficial impact on the corridor as construction activities would provide final solutions for some contaminated sites, lowering potential exposure in the future.

Phase I ESAs should be completed for each property acquired in order to be eligible for LLPs. If Recognized Environmental Conditions (RECs) are identified during the Phase I ESA process, the RECs should be addressed through clean-up or further investigation through a Phase II assessment. Based on the development histories of the properties and surrounding areas, it is advisable that the Nashua – Crown Street, Manchester – Granite Street, and Concord – Stickney Avenue properties be assessed for the presence of petroleum or hazardous substances that might require management or disposal, regardless of the findings of a Phase I ESA. Given the history and settings of these properties, assessment of subsurface conditions for the presence of VOCs, PAHs, PCBs, and Resource Conservation and Recovery Act (RCRA) 8 metals in soils is advisable. Assessment for asbestos should be considered for the Nashua – Crown Street property.

4.4 Water Quality

Surface water quality is regulated statewide by the NHDES under rules found at Env-Wq 1700, in Massachusetts under regulations 314 CMR 4.00 and nationally by the USEPA under the Clean Water Act (CWA). Surface water bodies were identified using available mapping, such as National Wetland Inventory Maps, the New Hampshire Wetlands Base Map, Massachusetts Geographic Information System (MassGIS), U.S. Geologic Survey (USGS) topographic maps, and aerial photographs. Additional detail can be found in the Natural Resources Technical Report in Appendix D.

4.4.1 Affected Environment

The dominant surface water feature within the Study corridor is the Merrimack River, which flows from north to south through the entire corridor from Concord to Nashua to Lowell. The existing rail line parallels the Merrimack River crossing it twice: once in the Town of Hooksett and again from the City of Manchester to the Town of Bedford. Based upon a review of USGS topographic maps and the NHDES Watershed Report Cards, the existing rail corridor crosses 25 other rivers or streams between the Massachusetts border and the end of the project Study area in Concord. Two crossings (Baker Brook and Spit Brook) occur in urban areas of Manchester and Nashua, respectively, and flow through culverts instead of natural channels. In addition, Horseshoe Pond in Merrimack, South End Marsh in Concord and an unnamed pond in Concord, as well as numerous wetlands, are also located within 100 feet of the existing rail line.

The Study corridor is not located near any Outstanding Resource Waters, as designated by the Massachusetts Surface Water Quality Standards (314 CMR 4.00) and NHDES Regulation Env-Wq 1708.05.

4.4.2 Intercity 8 Alternative

Intercity 8 would not adversely impact water quality within the corridor as it is an existing rail line and improvements to drainage and stormwater management would be part of the project. The upgrade to culverts and associated stormwater BMPs along the entire length of the corridor, as well as at potential station locations, would have a net beneficial impact to water quality. The site design for each station, where new parking is being proposed, would be designed to meet applicable state stormwater standards and guidelines for the areas they are proposed. In addition, the existing corridor currently supports freight rail traffic, which does not contribute to the impairments of the Total Maximum Daily Loads (TMDLs) that have been developed for the impaired water bodies in the corridor. It is not anticipated (based on the passenger rail operating characteristics) that the four round trips per day would contribute to the existing impairments in the corridor.

There would be, however, negligible to minor, short-term, localized impacts during construction activities in the corridor. The relatively short and temporary duration of these activities, combined with appropriate sediment containment and construction BMPs, would ensure that any impacts are negligible to minor.

4.5 Wetlands

Wetlands are federally protected under the CWA and activities resulting in impacts to them require a permit from the U.S. Army Corps of Engineers (USACE) under Section 404 of the CWA. Wetlands are also protected under State of New Hampshire statutes, with permits obtained through the NHDES Wetlands Bureau. Wetlands are also regulated at the state-level by the Massachusetts Wetlands Protection Act (WPA), which is administered by the municipal conservation commissions, with overview by the MassDEP.

Wetlands along the project corridor were not field-delineated, but were identified using available mapping, including National Wetland Inventory Maps, the New Hampshire Wetlands Base Map, MassGIS, USGS topographic maps, and aerial photographs. Field reviews of the proposed station and layover facilities were conducted in order to obtain more accurate information on wetland resources. Approximate wetland boundaries within and adjacent to the proposed facilities were mapped using Global Positioning System (GPS), but wetland delineation flags were not placed in the field and surveyed. Additional detail can be found in the Natural Resources Technical Report in Appendix D.

To more accurately evaluate wetland impacts and to apply for USACE and NHDES permits, a formal wetland delineation within the entire project corridor and the station and layover facilities will need to be conducted during the project's preliminary design phase.

4.5.1 Affected Environment

Wetland resources within the project corridor include palustrine and riverine systems that feed into the Merrimack River. Since the proposed rail corridor follows an existing railroad embankment, wetland and stream crossings have bridges or culverts. As a result, wetland systems crossed by the rail embankment have already been impacted by the placement of fill and culverts. Table 4.7 provides a summary of the large wetland systems that are located along the project corridor.

Prime wetlands within the project corridor are located in the municipalities of Hooksett and Nashua. Prime wetlands are identified in Table 4.7 (Large Wetland Systems). Within the City of Nashua, the Merrimack River, the Nashua River, and Salmon Brook are also considered prime wetlands. None of the prime wetlands within the project corridor have a 100-foot buffer zone.

Table 4.7: Major New Hampshire Wetlands in Corridor

Town	Federal Classification	Prime Wetlands	Description
Concord	PUBH, PUBF, PEM1F, PSS1E, PFO1E	No	Located near I-93, Exit 12;includes "South End Marsh" (conservation land owned by the City of Concord) and a NHDOT wetland mitigation area
Bow	PSS/EM1E, PSS1E, PUBHh, PUB/SS1F	No	Located near Public Service of New Hampshire (PSNH) facility; wetland system appears to have been altered by PSNH facility; Bow Bog Brook flows through wetland system
Hooksett	PSS1E, PUBHh	Yes	Includes wetlands and open water areas located between Route 3A and Merrimack River
Hooksett	PSS/EM1E	No	Wetland system associated with an unnamed tributary to Merrimack River; located between Dale Road and Merrimack River
Hooksett	PSS1E, PUBF	Yes	Wetland system associated with Messer Brook; located near Hooksett/Manchester town line
Manchester	PEM1F, PSS/EM1E, PFO/EM1E	No	Wetland system associated with unnamed tributaries to Merrimack River; located approximately 1 mile north of Amoskeag Street bridge
Merrimack	L1UBH, PSS1E, PSS1C	No	Horseshoe Pond and associated wetlands also includes Naticook Brook
Merrimack	PFO1E, PFO4E, PEM1Eb	N	Located near Mast Road, between Route 3 and Merrimack River
Nashua	R5UBHx, PUB/SS1Fh, PFO1E	Yes	Wetland system associated with Salmon Brook

In Massachusetts, these are the wetland and water resources within the corridor:

- Unnamed tributary to the Merrimack River and adjacent wetlands: Located north of Parlee Farms in Tyngsborough
- Bridge Meadow Brook: Located north of the Route 3A bridge over the Merrimack River in Tyngsborough
- Unnamed tributary to the Merrimack River (flows from Uptons Pond): Located in Tyngsborough near intersection of Route 3A and Westford Road
- Deep Brook and adjacent wetlands: Located in Chelmsford near Wotton Street
- Stony Brook and adjacent wetlands: Located in Chelmsford near Church Street

- Black Brook: Located in Lowell near the intersection of Middlesex Street and Pawtucket Street and appears to be piped under the project corridor and the surrounding urban area
- Pawtucket Canal: Located in Lowell and is crossed twice by the project corridor
- River Meadow Brook: Located in Lowell near the Lowell Connector and the southern end of the project corridor

4.5.2 Intercity 8 Alternative

Intercity 8 would have no impact in most areas of the corridor and minor temporary and permanent impacts to jurisdictional wetland resource areas in a few discrete areas of the corridor. Minor temporary impacts may occur during construction activities, such as replacing or rehabilitating bridges or culverts, relocating utilities for track work, and grading work associated with station construction. These impacts would be mitigated during design and restored after construction has been completed. Minor permanent impacts may occur during these same activities in cases where temporary impacts cannot be restored in-place. In these cases, compensatory mitigation would be identified at the appropriate ratio for replication. As more detail is developed in the project's next phase, these impacts will be defined in greater detail. Any wetland impacts would be subject to state and federal permitting requirements.

The following station sites are located in previously developed areas and no wetlands or watercourses are located within or adjacent to the site: Concord – Stickney Avenue, Manchester – Granite Street, and Nashua – Crown Street. The Bedford/Manchester Airport station has several wetlands and watercourses located at the site. North of Ray Wieczorek Drive, the majority of the site is forested wetland. South of Ray Wieczorek Drive, there are two small forested wetlands and one emergent/scrub-shrub wetland. These three wetlands drain to Sebbins Brook, which flows into the Merrimack River. As currently designed, this station would impact less than 1,000 square feet of wetland at this site.

4.6 Threatened and Endangered Species

Endangered species are provided protection on both federal and state levels. The Federal Endangered Species Act of 1973 (16 USC 1531-1543, Sec. 2A) is the federal legislation that provides protection, while the State of New Hampshire protects species through the Native Plant Protection Act of 1987 and the New Hampshire Endangered Species Conservation Act of 1979. The State of Massachusetts protects species through the Massachusetts Endangered Species Act (M.G.L. c.131A). The Massachusetts Natural Heritage and Endangered Species Program (NHESP) is the state agency responsible for the protection of plant and animal species that are listed as threatened, endangered, and of special concern in Massachusetts.

Information on important wildlife habitat and recorded occurrences of rare, threatened, and endangered species was obtained from the New Hampshire Natural Heritage Bureau (NHB), the Massachusetts NHESP and MassGIS website. Additional detail can be found in the Natural Resources Technical Report in Appendix D.

4.6.1 Affected Environment

NHB identified the following species of concern in the project corridor: bald eagle (*Haliaeetus leucocephalus*), peregrine falcon (*Falco peregrinus*), eastern hognose snake (*Heterodon platirhinos*), New England cottontail (*Sylvilagus transitionalis*), and grasshopper sparrow (*Ammodramus savannarum*). NHESP identified three species of concern within the project corridor, including bald eagle, riverine clubtail (*Stylurus amnicola*), and cobra clubtail (*Gomphus vastus*). A full listing of threatened and endangered species can be found in the Natural Resources Technical Report in Appendix D to this report.

NHB also listed exemplary natural communities in the corridor, including Acidic Riverside Seep, Dry Appalachian Oak Forest, Pitch Pine – Scrub Oak Woodland, Semi-Rich Oak – Sugar Maple Forest, and Sugar Maple – Silver Maple – White Ash Floodplain Forest.

4.6.2 Intercity 8 Alternative

Intercity 8 would not adversely impact federal and state regulated wildlife habitats. At this level of the project, neither state agency has ruled on whether the project would qualify as a "take" under the regulations (this will be confirmed during the next NEPA documentation); however, based on preliminary conversations over project design aspects, it is not anticipated Intercity 8 would adversely impact threatened or endangered species. The major concern is over destruction of habitat, and as currently designed, the project would require limited vegetation removal as stations are located in previously developed areas, and the existing rail right-of-way has been maintained to control vegetation in the past.

More details on the existing rail line, the proposed improvements, and vegetation clearing will need to be provided to New Hampshire Fish and Game, NHB, and NHESP as the project design progresses. The project will need to be reviewed under the Massachusetts Endangered Species Act (MESA) and an application will need to be filed with NHESP. It is recommended that continued coordination with these agencies occur during the project design phases to obtain feedback and determine the need for any field surveys.

4.7 Floodplains

The Digital Flood Insurance Rate Maps (DFIRMs) available on the New Hampshire Geographically Referenced Analysis and Information Transfer System (NH GRANIT) GIS website and MassGIS website were reviewed to determine the locations of flood hazard areas within the project corridor. Since the rail corridor is located along the Merrimack River, a large portion of the project is located within or adjacent to areas that are mapped as 100-year floodplains. Additional detail can be found in the Natural Resources Technical Report in Appendix D.

4.7.1 Affected Environment

Most of the proposed station and layover facility sites in New Hampshire are located within or adjacent to floodplain areas. These areas are generally mapped as either "Zone AE" (100-year floodplain or 1 percent annual chance of flood) or "0.2 percent annual chance of flood hazard" (500-year floodplain). Portions of the downtown Nashua site are mapped as "Zone X, Protected by Levee."

The project corridor crosses through the 100-year floodplain (Zones A and AE) in several locations in Massachusetts. These floodplains are associated with the Merrimack River and its larger tributaries (Deep Brook, Stony Brook, Pawtucket Canal, and River Meadow Brook). The largest Zone A floodplain area is located in Chelmsford, where approximately one mile of proposed new rail (double-track on the existing embankment) is located within an area mapped as Zone A floodplain.

4.7.2 Intercity 8 Alternative

Intercity 8 would have minor to negligible impacts to floodplains in the project corridor. As the existing rail right-of-way runs adjacent to the Merrimack River and in many cases is less than 250 feet from the river bank, impacts to floodplains would be unavoidable in certain discrete sections of the corridor. However, within the existing right-of-way, the project corridor historically carried two tracks along its entire length, and Intercity 8 calls for restoring that second track on the existing embankment in certain locations. To the extent practicable, the design team has located station elements outside of floodplains. In locations where floodplain elevations would be altered, the project would provide compensatory floodplain storage. Through mitigation, adverse impacts to floodplains would be kept to a minimum.

4.8 Energy Resources

Energy resources are measured over time and related to the energy consumption and GHG emissions from the construction and the operation of the project (see Section 4.1 Air Quality and Greenhouse Gas Emissions). New Hampshire's transportation sector accounted for 35 percent of New Hampshire's energy consumption in 2011[10] and ranked 41st nationally in VMT with over 12,894 million miles (2012).[11] This project would help reduce the state's VMT and overall energy consumption by offering a new passenger rail service and reducing the number vehicles on the state's roadways.

4.8.1 Affected Environment

The project would impact energy sources during project construction and during new passenger rail service operation. Energy resources would be required to build the station facilities and operate the trains and other project facilities. Operation of the service would also require energy.

4.8.2 Intercity 8 Alternative

Intercity 8 would introduce passenger rail operations, which currently do not exist in the corridor. This service is expected to divert trips from vehicles to passenger rail, reducing the overall VMT and GHG emissions. However, Intercity 8 could potentially have a minor adverse impact on traffic operations around certain station locations. As described in the Air Quality Section (Section 4.1), emission increases related to traffic for Intercity 8 are below the minimum threshold for a conformity determination.

[10] U.S. Energy Information Administration, www.eia.gov/state/?sid=NH
[11] U.S. Energy Information Administration, http://www.eia.gov/state/print.cfm?sid=NH

Intercity 8 would create a net emission reduction benefit from the saving of vehicle trips for some pollutants (CO and SO_2).

During construction, the project would consume energy through the processing of materials and construction activities. All impacts, during construction will be addressed in the next level of analysis.

4.9 Visual Resources

Visual resources in the corridor were analyzed as part of the historic architecture work developed for the project. A field survey conducted in the corridor was supplemented with map research and historic documentation. In addition to historic buildings and districts identified for this area, other items identified included significant features, parks, and significant natural resources.

4.9.1 Affected Environment

The most significant natural resource in the corridor is the Merrimack River, which runs adjacent to the rail right-of-way for its entire length, and in some cases is less than 250 feet away. In addition to the river, there are three wetland systems that are classified as "prime" wetlands in New Hampshire – two in Hooksett and one in Nashua. The rail right-of-way also abuts several parks/recreation areas along the route.

As documented in greater detail in Section 4.15 Cultural Resources, there are a number of aboveground historic properties and historic districts adjacent to the rail right-of-way. In addition to historic build resources, the corridor is a highly developed, urban landscape in Lowell, Nashua, Manchester, and Concord, and a less developed, rural landscape in the those towns between the major urban areas. Generally, the significant natural resources are located outside of the urban areas, and the historic built resources are located within the urban areas.

4.9.2 Intercity 8 Alternative

For work associated with the rail line, including infrastructure associated with upgrading the existing rail and adding double-track, Intercity 8 would have no impact on visual resources as the rail right-of-way historically accommodated double-tracking throughout corridor length. For the work associated with the stations and layover facility, Intercity 8 would have negligible impacts to visual resources as the stations would be built in underutilized, previously developed land and none of the new stations would be built in an existing historic district. In addition, the stations would consist of mini-high platforms, which do not require building large pedestrian crossovers at each station.

4.10 Accessibility

The Americans with Disabilities Act (ADA) of 1990 requires that persons with disabilities be accommodated for all public facilities including transportation. All stations and transportation facilities must meet the ADA design standards and applicable state and local codes.

4.10.1 Affected Environment

The accessibility evaluation focused on how the alternatives impacted accessibility for patrons with disabilities. Intercity 8 would make four stops in New Hampshire (Concord, Manchester, Bedford/Manchester Airport, Nashua), in addition to three existing Massachusetts commuter rail stops (Lowell, Woburn, and Boston) in Massachusetts. The four new stations would provide a mix of high- and low-level platforms with "mini-high" platforms based on MBTA design standards for handicapped accessibility. High-level platforms would be preferred at all locations.

4.10.2 Intercity 8 Alternative

Intercity 8 would have a beneficial impact on accessibility as it would meet all ADA design standards and applicable state and local codes. Station design would include level boarding between the platform and train. Ramps would be included from the parking lots to the raised station platforms. The proposed park-and-ride lots would provide handicap accessible parking spaces. All station facilities would be ADA accessible.

4.11 Property Acquisition

Property acquisition requirements were determined based on the selection of preferred station locations in the corridor and through research of assessor's databases in the affected towns. The existing rail right-of-way is of sufficient width to accommodate the proposed track work for the project. The focus of this section is on station development.

4.11.1 Affected Environment

Four station locations were developed through research on previously planning studies in the corridor, workshops with local stakeholders in each community, and the Study team's professional judgment. In Concord, the preferred station location and layover facility is located on property owned by NHDOT, which consists of buildings that are no longer in use by the department. Part of the station work would require relocating the track in this area, which would require acquisition of one privately-held parcel. In Manchester, the preferred station location would require coordination with the City of Manchester, as the proposed platform and parking is located at an existing municipally owned parking lot. At Bedford/Manchester Airport, the majority of land in the vicinity of this location has been previously acquired by the state during the construction of the Ray Wieczorek Drive Bridge. There is one parcel still in private ownership that is leased to a natural gas company, which would be impacted by the project. In Nashua, the preferred station location would require coordination with the City of Nashua, as the parcel for the platform and parking is located on municipally-owned lot.

4.11.2 Intercity 8 Alternative

Intercity 8 would have minor impacts on privately held property in the corridor, as the station development would only require acquisition of two privately-held parcels. The remaining land for development is owned by the state or by the municipality. These properties are generally underdeveloped/underutilized and would see substantial benefit with the development of stations at

these locations (see Section 4.17 Socioeconomics). The one parcel with the most impact is located at the Bedford/Manchester Airport site, as it is currently developed and utilized as a natural gas storage location.

4.12 Land Use

The land use and zoning evaluation focused on whether the proposed stations would support transit, mixed use development, and park-and-ride lots. Data was gathered through field visits and focus groups in Concord, Manchester and Nashua (additional details available under separate cover, Appendix H, Public Involvement). The purpose of the focus groups was to hear participants' perceptions of TOD, proposed project impacts, and preferences for implementation. The project established a set of sustainable land use goals supported by purpose and need:

- Environmental Goals:
    - Catalyze more compact, infill rail-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power) to support new development, and supporting maintenance of existing open/rural space
    - Reduce reliance on cars for trips/errands
- Social Goals:
    - Expand mobility and transportation choice for all age groups
    - Support low-income households through increased access to jobs
- Economic Goals:
    - Attract employers to New Hampshire
    - Attract and retain regional employers to New Hampshire and Boston
    - Provide improved residency location choice in New Hampshire for commuters to Boston or regional jobs

4.12.1 Affected Environment

The Study team evaluated each proposed station through a qualitative rating system based on five criteria as defined by the FTA for TOD: economic climate for development, capacity of land in station areas, existing plans and policies, urban design and connectivity, and TOD potential. The first four criteria consider attributes of the proposed station areas, defined as a half-mile radius around potential rail stations; the fifth criterion evaluates TOD potential based on the mode and service characteristics of the various alternatives.

Concord – Stickney Avenue: The City of Concord has experienced positive redevelopment in the downtown and adjacent areas, with proximity to the proposed station area.

Manchester – Granite Street: Manchester downtown, north of Granite Street has a high economic climate for development as well as appropriate urban design and connectivity. There are plans and policies in-place that support TOD. This area has a limited amount of developable land surrounding the station area. South of Granite Street the economic climate for development is not as high as north of Granite. There is more land available around the stations and there are plans and policies in-place that support TOD. Urban design and connectivity is suitable for TOD.

Bedford/Manchester Airport: The Bedford/Manchester Airport station has less of an economic climate for development. It has a very limited amount of developable land surrounding the station and there are no plans and policies in-place that support TOD. There is also little pedestrian-scale urban design and connectivity in the vicinity of the station.

Nashua – Crown Street: The Nashua Crown Street Station has some economic climate for development. There is a fair amount of capacity of land around the station areas. Some plans and policies are in-place that supports TOD. The urban design of the areas surrounding the station is not as walkable as some of the other stations.

4.12.2 Intercity 8 Alternative

Based on a qualitative assessment, it is anticipated that Intercity 8 would have moderate impact on the project's sustainable land use goals. Intercity 8 would have a low-to-medium impact on catalyzing more compact, infill transit-supported land use and development patterns around the stations, and would reduce reliance on vehicles for trips and errands. Intercity 8 also has a low-to-medium impact on expanding mobility and transportation choices for all ages and supporting low-income communities with access to jobs. Intercity 8 would have a medium impact on attracting employers to New Hampshire and retaining and attracting employers from New Hampshire to Boston, and would improve residency location choice in New Hampshire for commuters to Boston or regional jobs.

4.13 Environmental Justice

Equitable access to transit investments – and the mobility benefits that these investments provide riders – is an important consideration when assessing the intercity rail alternative developed for the Capitol Corridor. Public transit investment supports broad improvements in mobility, but is a particularly critical tool in increasing the mobility of transit-reliant or -dependent populations, including households below the poverty line, minorities, and households in affordable housing units.

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, issued in 1994, states that "each Federal agency shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations."

DOT Order 5610.2(a), *Department of Transportation Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, directs federal agencies to address environmental and human health conditions in minority and low-income communities. EJ areas are defined as census block groups that represent neighborhoods of high-minority, low-income, non-English speaking, and foreign-born populations.

4.13.1 Affected Environment

U.S. Census data was used to calculate statistics related to income, race, and housing for households and individuals in Census tracts within a half-mile of Intercity 8. Data was collected for New Hampshire and Massachusetts, and the U.S. for overall comparison. The Equity Analysis Report is found in Appendix F.

Income is an important element of the equity analysis because the costs associated with car ownership are relatively fixed, and can consume a comparatively larger percentage of lower-income household budgets. Access to transit allows households to maintain mobility and access while reducing the household expenditures on transportation, which then increases the amount of discretionary budget available to the household. Table 4.8 provides the median income of households in Census tracts within a half-mile of Intercity 8 stations, as well as the percent of the population within a half-mile whose household income falls below the federal poverty line. While median household income within the Capitol Corridor is comparatively high, median household income declines in the urban areas. The poverty levels are comparatively higher in the central areas of Concord, Manchester, and Nashua. The poverty level in these downtowns ranges from 18 to 30 percent. Transit investments that directly serve these urban households living below the poverty line would promote equity through increased access to comparatively lower-cost transportation options.

Minority populations represent between five and 26 percent of the population in Census tracts within a half-mile of the intercity rail stations, as shown in Table 4.8. Though this range is higher than the minority population found within the state of New Hampshire (six percent), most station areas have a lower percent of minority population than in the State of Massachusetts (19 percent) and the U.S. (26 percent).

Concord, Manchester, and Nashua each have affordable housing developments within a half-mile radius of the potential rail station locations. These affordable residences coupled with lower-cost transportation alternatives can help to reduce the share of household income spent on transportation costs.

Table 4.8: Equity Metrics in the Capitol Corridor

Station Area (Half-Mile Buffer)	Proposed Rail Station	Equity Metrics			
		Average Median Income	Population Below Poverty	Minority Population	Affordable Housing Units
Concord, NH	X	$39,000	18.0%	9.7%	398
Manchester, NH	X	$30,300	29.5%	26.1%	675
Bedford/MHT	X	$65,500	4.5%	5.2%	0
Nashua, NH: Crown Street	X	$52,500	14.9%	12.2%	28

4.13.2 Intercity 8 Alternative

Intercity 8 would have a major beneficial impact for EJ populations within proximity to proposed stations in Concord, Manchester, and Nashua, as the project provides increased access to transportation options within the corridor. Potentially minor adverse impacts to certain populations include the noise impacts of horns within certain communities. The noise impacts and mitigation are addressed under the Noise and Vibration, Section 4.2 of this report.

4.14 Public Safety

Increasing rail traffic in the corridor would increase the likelihood of conflicts between rail operations, traffic operations, and pedestrian movements. Existing railroad safety features were evaluated with the owner, PAR, and through field reconnaissance and GIS mapping. Of particular concern were interlockings, block signals, and at-grade crossings.

4.14.1 Affected Environment

The train control signal system for the route supports NORAC Rule 261 between North Station and Manchester. Rule 261 allows for bi-directional train operation with automatic wayside block signals on all main line tracks. North of Manchester, there are no wayside signals and operations are governed by DCS rules, wherein a train order issued over the radio by the railroad dispatcher in Billerica, Massachusetts is necessary to move a train.

There are 35 locations identified between Lowell's Gallagher Terminal and Stickney Avenue in Concord where roadways or pedestrian paths cross the railway at grade. Grade crossings are of particular concern as they present the greatest accident hazard on the railway due to the potential for vehicle/pedestrian conflicts with trains. Grade crossings would require sensitive treatment should substantially greater volumes of trains be reintroduced along the route. Federal safety regulations require trains to sound their horns at all grade crossings. A federally sanctioned "quiet zone" may be established cooperatively with the local community working with the railroad to make substantial investments that reduce the likelihood of accidents.

The density of 35 crossings along the 48-mile route is relatively low for an intercity railroad. The railroad generally follows the banks of the Merrimack River and only several of the streets are heavily travelled. Most of the grade crossings lead to relatively small riverfront residential enclaves or industrial sites. Of the 35 grade crossings, 21 are public roads, 13 are private driveways, and one is an informal community crossing.

Public grade crossings are roadways that are under the jurisdiction of and maintained by a public authority. Private grade crossings are on privately-owned roadways such as those leading into an apartment complex, housing estate, or commercial/industrial development. A private crossing is not intended for public use and is not maintained by a public road authority.

4.14.2 Intercity 8 Alternative

Intercity 8 would have a beneficial impact in the project corridor through mitigation and upgraded safety features. The existing railroad (NHML) has a fully functioning CTC signal system in-place between Lowell and Manchester that would be renewed and upgraded for the new passenger service. Existing block signals were identified by reference to PAR documentation. New and renewed interlockings were identified in the track configuration planning process. In addition, the project includes installing all new equipment for the AHWD. It is also assumed that the rail line would operate with PTC, which is in the process of being incorporated in PAR, Amtrak, and MBTA facilities around New England, and would be in-place by the time this route is operational.

4.15 Cultural Resources

A Phase IA survey was conducted for the proposed construction area of potential effect (APE) from Lowell, Massachusetts up to Concord, New Hampshire, for the section of corridor that would be under construction. The proposed APE was examined to establish the archeological potential of the Study corridor as well as determine the impact of the proposed construction on extant historic structures. This effort combined a review of the known prehistoric and historic sites as well as a survey of historic maps of the region from which were synthesized a determination of archeological potential. In addition, a historic architecture survey of the proposed construction APE consisted of an inventory of previously identified historic properties recorded within or adjacent to the proposed APE and a windshield survey of the project APE. The Cultural Resources Technical Report can be found in Appendix G. The State Historic Preservation Offices (SHPOs) of Massachusetts and New Hampshire have been coordinated with for this project.

4.15.1 Affected Environment

Historic Architecture: In New Hampshire, there are two previously identified historic properties within the direct APE: the Eagle Square Historic District and the Amoskeag Millyard Historic District, as well as 14 previously identified historic properties within the indirect APE. Background research and the field visit also found that there are 12 resources over 50 years of age within the direct APE that have not

been previously surveyed, including the rail line itself, and two bridges that carry the rail line over the Merrimack River.

In Massachusetts, background research gathered from Massachusetts Cultural Resource Information System (MACRIS), a Massachusetts Historical Commission (MHC) visit, and other online sources determined that there are four Massachusetts Historical Commission (NRHP)-listed resources in the APE. One of those resources, the Lowell Locks and Canals Historic District is also a National Historic Landmark (NHL). The other three are the Lowell Historic Preservation District, Lowell National Historic Park, and Middlesex Canal Historic and Archeological District. In addition, background research and the field visit determined that there are two previously unidentified properties that may be 50 years of age or older within the direct APE. This includes the rail line itself, and one of the bridges that carries the rail line over the Pawtucket Canal.

Archeology: In New Hampshire, overall, the prehistoric potential for the Study areas remained consistently high, owing in large part to the proximity of the construction APE to the Merrimack River. The historical archeological sensitivity was also determined to be high given the density of historic settlement within the Study area. The archeological sensitivity for historic archeological resources was subdivided into site types. Analysis of these site types revealed that sites of an industrial- or transportation-related association were the most likely form of historic archeological material to be encountered. Both of these site types were frequently situated along the river and its tributaries from which they derived operational power and transportation. As the extant rail bed follows the course of the Merrimack River, the likelihood of encountering industry/transportation-related resources is therefore high. For a full listing of archeological sites and potential in New Hampshire, see Appendix G.

In Massachusetts, the Lowell Study area contains a total of 33 identified archeological sites. Within the Lowell Study area, 21 sites are classified as historic sites and 12 sites are classified as prehistoric. Of the 33 previously identified archeological sites contained within the Lowell Study area, no site occurs within the extant railroad bed which forms the project APE; however, several sites do occur in close proximity, namely the Railroad Site (19-MD-0570[12]) and the B&M Roundhouse Site (LOW-HA-31[13]), both of which are immediately adjacent to the current main line.

4.15.2 Intercity 8 Alternative

Historic Architecture: Intercity 8 would have no impact on Historic Architectural Resources. Historically, this line contained a double-track, but sometime in the 20th century, the second track was abandoned except for the section from Lowell to Stony Brook and selected sidings north to Concord. Since the project would be limited to the existing right-of-way and would only consist of replacing the second track in selected locations that existed historically, there is very little possibility for physical impacts and no possibility for visual impacts. As a result, no additional work is recommended.

[12] Massachusetts site from the SHPO
[13] Massachusetts site from the SHPO

Although no impact is projected for this resource, based on the information currently available, it is recommended that an intensive-level historic architectural survey be conducted to determine whether or not the resources 12 resources in the direct APE that have not previously been surveyed are eligible for listing in the NRHP.

Archeology: Intercity 8 would have minor to negligible impacts to Archeological Resources. The majority of work proposed for this project would be located in previously disturbed track bed or in highly developed areas. However, as the archeological potential of the area is generally high, precautions would be put in-place to mitigate adverse impacts to the resources.

Any activity associated with the construction effort – including but not limited to the establishment of access roads, drainage, removal of existing railroad bed or other soil caps, or the establishment of new sections of rail bed – will all need to be monitored by a qualified archeologists or subjected to an intensive Phase 1B field survey prior to commencement of work to ensure that there are no cultural resources present that might be adversely effected by that action. Additionally, the placement of any support/maintenance facilities or construction staging areas will require Phase 1B testing prior to their construction or usage to ensure that no cultural resources are negatively impacted.

4.16 Section 4(f)

The U.S. Department of Transportation Act of 1966, Section 4(f), requires DOT agencies to avoid, if feasible, certain resources when implementing transportation improvements. These resources, collectively referred to as Section 4(f) resources, include publicly-owned parks, recreation areas, wildlife or waterfowl refuges, or public or private historic properties of national, state, or local significance. These resources were identified using GIS mapping and field reconnaissance surveys to identify potential resources.

4.16.1 Affected Environment

There are a number of publicly-owned parks and recreation areas that are adjacent to the existing rail right-of-way, though none of them would be impacted by the projects, and, as such, do not qualify as Section 4(f) resources. The work associated with the rail would take place within existing right-of-way, and the stations would be located on either private or publicly-owned parcels that are not set aside as either park land or recreation land.

There are a number of NRHP-eligible resources within the corridor (see Section 4.15 Cultural Resources). Based on the level of detail included in the preliminary rail design, there is not yet enough information to determine whether any of the resources would be directly impacted by the project and, therefore, classified as a Section 4(f) resource. As the project design progresses, further coordination will occur with the appropriate agencies at the next NEPA documentation to make this determination and conduct a full Section 4(f) evaluation if necessary.

4.16.2 Intercity 8 Alternative

Intercity 8 would have an unknown impact on Section 4(f) resources in the corridor. As further detail is developed on the project, these impacts will be defined and evaluated at the next level of the NEPA process.

4.17 Socioeconomics

Economic benefits of transit investment were developed through examining the literature and findings from recent studies of similar regional transit enhancement projects. Numerous studies have identified a net positive benefit of transit investment to the regional economy, as a result of travel time savings and congestion reduction, expanded access to jobs and workforce, and new development attracted to station areas. Studies have also found a positive impact of transit on property values in station areas. While only a few studies have specifically examined commuter rail, evidence from other rail system expansions in the greater Boston region similarly suggests that transit investment would have a positive effect on the communities it serves.

Interviews were conducted with local stakeholders to gather information on the impact the different transit alternatives could have in bringing about new development over the next 20 years. The Study team also assembled data on land use and zoning to evaluate the potential impact of the Capitol Corridor alternatives on development and redevelopment. This potential was measured in terms of commercial square footage (office and retail) and housing units for the different alternatives.

Lastly, the economic modeling tool IMPLAN was used to estimate the economic benefits to the southern New Hampshire region of each Capitol Corridor rail alternative. The following economic benefits were evaluated:

- Short-term benefits as a result of spending on construction of rail improvements in New Hampshire
- Long-term benefits as a result of the attraction of more residents and jobs to southern New Hampshire; these include benefits from construction of new real estate, as well as ongoing benefits from new worker earnings reinvested in the local economy

4.17.1 Affected Environment

The Concord – Stickney Avenue station area site was identified as suitable for TOD, primarily due to the mixed-use and high-density residential allowances and flexible parking requirements under zoning. Parcels considered most likely to develop or redevelop due to transit alternatives were primarily located within the Opportunity Corridor Performance (OCP) district, the Gateway Performance District (GWP) and the Central Business Performance (CBP) district.

There is little vacant land within the Manchester – Granite Street station area. Due to the transit supportive zoning, however, many underutilized parcels could potentially redevelop in conjunction with the proposed rail service enhancements. Parcels considered likely to redevelop are predominantly

located within the CBD with some intensification possible in the residential district. This area is also considered suitable for TOD due to its high-density residential and commercial allowances under zoning.

Given the relatively low residential and commercial densities proximate to the proposed station area for the Bedford/Manchester Airport, this site has the least amount of development potential; however, there was a general consensus among interview participants that rail connectivity to the airport was critical for regional economic development.

The predominant zoning for the Nashua – Crown Street station area is multi-family residential and General Industrial. This analysis assumed development would be predominantly residential with a small amount of commercial use. A mixed use or TOD supportive overlay in this area would boost development potential, given the amount of vacant land suitable for development.

4.17.2 Intercity 8 Alternative

Intercity 8 would have a beneficial impact on the economics of the State of New Hampshire. This alternative, with four trains per day serving Nashua, Manchester, and Concord, could potentially generate about 1,600[14] new residential units and 819,000 square feet of commercial space supporting 2,480 new jobs by the year 2030, as shown in Table 4.9. It has the potential to generate 350 new jobs over the construction period (2019-2022), 2,460 jobs related to new real estate development between 2021 and 2030, and 1,140 new jobs annually in 2030 and beyond (with benefits beginning to accrue after 2021) due to reinvested worker earnings (see Table 4.10). Real estate development would add $750 million to the state's output between 2021 and 2030, with reinvested earnings adding $140 million per year beyond 2030.

Table 4.9: Development Potential at Each Station

Station	Commercial (Square Feet)	Residential (Units)	Jobs
Concord – Stickney Avenue	335,000	400	890
Manchester – Granite Street	284,000	680	1,020
Bedford/MHT	123,000	0	360
Nashua – Crown Street	77,000	560	210

Table 4.10: Impacts on Employment and Output

Intercity 8	Project Construction (2019-2022)	Real Estate Development (2021-2030)	Reinvested New Resident Earnings (Annual, 2030+)
Impact on Employment (Jobs)	350	2,460	1,140
Impacts on Output (Gross Regional Product In Millions of 2014$)	$100	$750	$140

[14] Rounded to the nearest 100th

4.18 Transportation

Rail operations for Intercity 8 were modeled using stringline diagrams (also referred to as time-distance diagrams) that plan the flow of traffic on the railroad and are designed to overlay on top of the existing MBTA and Amtrak operations that would share trackage south of Lowell (MBTA) and south of Woburn (Amtrak). Stations were designed to provide direct access from major routes or take advantage of dense areas of development that would most likely utilize the system. Ridership numbers at each station were used to estimate parking requirements. Accessibility at each station is driven by existing guidelines developed by Amtrak.

4.18.1 Affected Environment

As described in Section 1.3 Corridor Existing Conditions, the existing rail corridor is owned by PAR and utilized exclusively for freight rail traffic, with no passenger rail operations. See Section 1.3 for additional details.

4.18.2 Intercity 8 Alternative

Intercity 8 would have a beneficial impact on rail options and mobility in the corridor by increasing transportation options. The service would introduce passenger rail operations, which currently do not exist in the corridor. Intercity 8 could potentially have a minor adverse impact on traffic operations around certain station locations. As more detail is developed for the station alternatives and designs, traffic operations will be modeled in and around the proposed stations. Due to the inherent quality of train schedules, traffic in and around stations usually does not coincide with rush hour traffic. As a secondary impact to station design, development in and around stations would likely have a beneficial impact on accessibility and walkability in and around stations.

4.19 Indirect Effects and Cumulative Impacts

Indirect effects are defined in the CEQ regulations (40 CFR 1508.8) as those effects “which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable.” Cumulative impacts are defined in 40 CFR 1508.7 as the “impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions.”

4.19.1 Indirect Effects

Indirect effects associated with Intercity 8 have been documented in previous sections. Intercity 8 would have beneficial long-term effects due to induced growth and development around station locations. While the Bedford/Manchester Airport station is designed to specifically be a park-and-ride style station, the Town of Bedford has planning documents that include mixed use TOD-style development around this location if a station were built at this location. The remaining stations are each designed with TOD in mind, which would likely foster denser development and more walkable communities. This type of growth is generally favored over sprawl-type growth, and helps to protect the natural resources of the

state. In addition, as described in Section 4.17 Socioeconomics, Intercity 8 is expected to increase Gross Regional Product and jobs during construction and future operations.

4.19.2 Cumulative Impacts

A number of past, present, and future projects identified in the planning documentation for the region can be taken into account when analyzing the project cumulative impact scenario. The I-93 widening project is currently underway and serves as a major transportation connection within the corridor. Exit 36, located on US Route 3 in Massachusetts, was recently the subject of a planning study by the Southern New Hampshire Regional Planning Commission to study the impact of redesigning the interchange to allow southbound traffic to exit at this location (it currently only supports exiting from the northbound direction). In addition, there is a parallel study looking at extending MBTA commuter rail operations north of Lowell to Manchester. Lastly, it is assumed development patterns would be affected by these transportation improvements if they are implemented.

Under the cumulative impact scenario, Intercity 8 would have an incremental beneficial impact on the environment. The project would provide greater access to transportation options for people in the corridor and reduce VMT within the US Route 3 and I-93 travel corridors. In addition, the project is consistent with all local and regional plans and has been coordinated directly and transparently with the communities who would see the greatest impact from the project.

4.20 Construction Period Impacts

Construction period impacts are temporary during project implementation and will vary depending on the type of construction and location. Impacts are minimal and can be mitigated with construction best practices.

4.20.1 Affected Environment

The NHML previously accommodated two tracks along the entire length between Boston and Concord; however, aside from sidings, the rail line today is only single-tracked north of the wye at Stony Brook in Chelmsford. To accommodate new passenger rail, the existing rail has to be upgraded, and enough second track needs to be provided to accommodate both passenger rail and freight on the same line. No improvements south of MBTA's Lowell Gallagher Terminal would be required. North of Lowell the railroad would be upgraded to permit safe, reliable operation of eight daily passenger trains at speeds of up to 75 mph. Upgrades would be provided to track, bridges, crossings, and signals, which are summarized in Major Infrastructure Components, Section 3.2.6.

4.20.2 Intercity 8 Alternative

Minor temporary impacts may occur during construction activities, such as replacing or rehabilitating bridges or culverts, relocating utilities for track work and grading work associated with station construction. Noise associated with the construction of the project is expected to have four potential daytime impacts and up to 324 potential nighttime impacts have been identified as a result of the

analysis. These impacts would be mitigated during design and restored after construction has been completed. Minor permanent impacts may occur during these same activities in cases where temporary impacts cannot be restored in-place. In these cases, compensatory mitigation would be identified at the appropriate ratio for replication. As more detail is developed in the project's next phase, these impacts will be better defined.

5 Agency Coordination and Public Involvement

A Public and Stakeholder Involvement Plan (PSIP) was developed that outlines how the NHDOT – in cooperation with Federal FRA, FTA, and the Study team – would both educate and seek input from private entities, public agencies, communities, residents, and the traveling public. The PSIP's purpose was to describe how stakeholder and public input would be sought to inform the completion of key project milestones, including the definition of the Study Purpose and Need, the development of alternatives, the evaluation of alternatives, the selection of a recommended strategy, and the methods by which clear and understandable information would be developed and disseminated at the conclusion of each Study milestone. Activities described in this plan would educate key stakeholders and the public about the technical analyses that fed into the decision-making process and to receive input for that process.

A variety of approaches were used to inform stakeholders of Study activities and there were numerous opportunities for discussion and comment. Public opinion and comments were documented and considered throughout the process. The main objectives of the public and stakeholder outreach activities for the Capitol Corridor AA Study are as follows:

- Build support for the AA Study and service development planning process among different stakeholder groups
- Encourage stakeholders to engage in the development process
- Provide clear and understandable information at each step of the process
- Document public and stakeholder opinion as part of the decision-making process
- Create a high-level of transparency regarding how the project is conducted

Because the Study included rail transit service as an alternative in the State of New Hampshire, the Study attracted significant interest from public and private stakeholders throughout the region, as well as members of the general public. Public and stakeholder outreach began at Study initiation and was proactive, consistent, and timely to fully engage the public and key stakeholders in the process. Federal, state, and local agencies with regulatory authority were contacted throughout the process to provide input and comment. In addition, NHDOT identified quasi- and non-governmental stakeholders, and

solicited comments through public information meetings, PAC meetings, a project website, and other activities.

5.1 Agency and Stakeholder Coordination

The Study team and NHDOT conducted 91 stakeholder meetings, three PAC meetings, and three public meetings (in Concord, Manchester, and Nashua) over the Study's 21-month lifecycle. The initial phase of stakeholder engagement was designed to solicit input from a broad, diverse range of players who all have a stake in the future of passenger rail in New Hampshire.

5.1.1 Project Advisory Committee

The PAC provided input to the Study, including the vetting of early, preliminary alternatives. Throughout the Study, the PAC held meetings (including ongoing Study progress discussions) that coincided with the conclusion of major Study milestones and phases. The Study team coordinated the PAC's efforts. In addition, the Governor's Office, Congressional Delegation Offices, Executive Councilors, and State Senators and State Representatives from communities along the Capitol Corridor were notified of all meetings (public meetings and PAC meetings). Information on the PAC meetings is provided in Appendix H.

The following organizations were PAC members:

- Amtrak
- Central New Hampshire Regional Planning Commission
- City of Concord, New Hampshire
- City of Manchester, New Hampshire
- City of Nashua, New Hampshire/Nashua Transit System
- Conservation Law Foundation of New Hampshire
- The Greater Concord Chamber of Commerce
- The Greater Nashua Chamber of Commerce
- Lowell Regional Transit Authority
- Manchester Transit Authority
- Manchester-Boston Regional Airport
- Massachusetts Bay Transportation Authority
- Massachusetts Department of Transportation
- Merrimack Valley Planning Commission
- Nashua Regional Planning Commission
- New Hampshire Rail Transit Authority
- Northern Middlesex Council of Governments
- Pan Am Railways

- Rockingham Planning Commission
- Southern New Hampshire Planning Commission

5.1.2 Other Stakeholders

One-on-one interviews and group briefings were held early in the Study with representatives of stakeholder groups identified by the Study team in consultation with NHDOT. These sessions allowed NHDOT and the Study team to convey information about the Study' scope and process and gain an understanding of stakeholders' perceptions of the Study, sensitivities associated with the project, and how local communities might react to the project. Stakeholders also provided information on other individuals and organizations that might have a particular interest in or provide support for the project.

Following is a list of stakeholders and a brief description of each.

- Anagnost Companies: Manchester developer
- C&J Trailways: Regional bus service provider in the Study area
- Central New Hampshire Regional Planning Commission (RPC): Planning commission serving 20 communities in Central New Hampshire, including the City of Concord
- City of Concord, New Hampshire
- City of Dover, New Hampshire
- City of Manchester, New Hampshire – Board of Aldermen: Legislative body of the City of Manchester
- City of Manchester, New Hampshire – Mayor's Office: Executive Office of the City of Manchester
- City of Nashua, New Hampshire/Nashua Transit System: Second largest city in New Hampshire; both Route 3 and existing rail line runs through the city
- Concord Area Transit: Public transit provider in the City of Concord
- Greater Concord Chamber of Commerce: Business advocacy organization representing businesses in the Central New Hampshire region
- Concord Coach/Dartmouth Coach/Boston Express: Regional bus service providers in the Study area
- Conservation Law Foundation: Non-profit focusing on environmental issues in New England
- FRA: Grantee for the portion of the Study to develop a Service Development Plan and related documents for intercity passenger rail service in the corridor between Boston and Concord
- FTA: Grantee for the portion of the Study to provide an AA for transit service in the Concord-Boston corridor
- Mount Washington College, Manchester, New Hampshire
- Lowell Regional Transit Authority: Public transit provider in the greater Lowell region
- Greater Manchester Chamber of Commerce: Business advocacy organization representing businesses in the Manchester region

- Manchester Community College, Manchester, New Hampshire
- Manchester Transit Authority: Public transit provider in the greater Manchester region
- Manchester-Boston Regional Airport (Manchester Airport): Public airport located in Manchester, New Hampshire
- MassDOT)/ MBTA: MassDOT is the state agency that coordinates, plans, and funds all public transportation infrastructure within the Commonwealth; MassDOT oversees the MBTA, which is responsible for providing public transit service to 176 cities and towns in Massachusetts
- Massachusetts Historical Commission: Established in 1963 to identify, evaluate, and protect important historical and archeological assets of the Commonwealth
- Merrimack Chamber of Commerce: Business advocacy organization representing businesses in the Merrimack region
- Merrimack Valley Planning Commission: Regional planning agency serving 15 communities in the northeast region of Massachusetts
- Greater Nashua Chamber of Commerce: Business advocacy organization representing businesses in the Southern New Hampshire region
- Nashua RPC: Planning commission serving 13 communities in Southern New Hampshire, including the City of Nashua
- National Railroad Passenger Corporation (Amtrak): Publicly-supported service that operates intercity passenger rail service throughout the U.S.
- New Hampshire Rail Transit Authority (NHRTA): Established by the legislature in 2007 for the general purpose of developing and providing commuter rail or other similar forms of passenger rail service; the authority is administratively attached to NHDOT
- New Hampshire Technical Institute, Concord, New Hampshire
- New Hampshire Congressional Delegates: Senators Jeanne Shaheen and Kelly Ayotte; Representatives Carol Shea-Porter and Annie Kuster
- New Hampshire Department of Environmental Services (NHDES): State agency concerned with the protection and wise management of New Hampshire's environment
- New Hampshire Department of Resources and Economic Development (NHDRED): State agency concerned with economic development in the State of New Hampshire
- New Hampshire Division of Historical Resources: Established as the State Historic Preservation Office in 1974 to preserve the historical, archeological, architectural, and cultural resources of New Hampshire
- Northern New England Passenger Rail Authority/*Downeaster*: Amtrak's rail service from Massachusetts to Maine
- PAR: Operator of more than 2,000 route miles of railroad in the Northeast, including the track included in the Study corridor

- Public Service of New Hampshire (PSNH): New Hampshire's largest electric utility and owner/operator of the coal-fired Merrimack Station in Bow, New Hampshire
- Rivier University, Nashua, New Hampshire
- Rockingham Planning Commission: Planning commission serving the southernmost corridor communities
- Southern New Hampshire University, Manchester, New Hampshire
- Southern New Hampshire Planning Commission: Planning commission serving 13 communities in Southern New Hampshire, including the City of Manchester
- The Duprey Companies: Concord, New Hampshire Developer
- The Northern Middlesex Council of Governments: Regional planning agency serving nine communities in the Northeast region of Massachusetts
- Town of Bedford, New Hampshire
- Town of Bow, New Hampshire
- Town of Durham, New Hampshire
- Town of Exeter, New Hampshire
- Town of Hooksett, New Hampshire
- Town of Hudson, New Hampshire
- Town of Litchfield, New Hampshire
- Town of Merrimack, New Hampshire
- University of New Hampshire

Notes and details of stakeholder meetings can be found in Appendix H.

5.2 Public Involvement

The Study team held three public meetings at key Study milestones, one of which was a scoping meeting to satisfy FRA requirements:

- Study Initiation Public Meeting, Manchester, New Hampshire – June 5, 2013
- Public Scoping Meeting, Concord, New Hampshire – March 5, 2014
- Final Alternatives Meeting, Nashua, New Hampshire – November 20, 2014

Public meeting documentation can be found in Appendix H. Table 5.1 is a summary stakeholder outreach activities.

Table 5.11: Stakeholder Outreach Summary

Date	Stakeholder
3/11/2013	Central New Hampshire RPC
3/12/2013	NHRTA
3/12/2013	City of Nashua, New Hampshire
3/12/2013	Nashua Chamber of Commerce
3/12/2013	Concord Area Transit
3/12/2013	Concord Coach/Dartmouth Coach/Boston Express
3/13/2013	FRA
3/13/2013	FTA
3/13/2013	Nashua RPC
3/13/2013	Southern New Hampshire RPC
3/13/2013	Manchester Chamber of Commerce
3/13/2013	Manchester Airport
3/14/2013	Manchester Transit Authority
4/2/2013	Mayor of the City of Manchester, New Hampshire
4/2/2013	Conservation Law Foundation
4/3/2013	MBTA
4/3/2013	MassDOT
4/3/2013	Northern New England Passenger Rail Authority
4/3/2013	Town of Durham, New Hampshire
4/3/2013	University of New Hampshire
4/16/2013	Senator Shaheen District Office
4/16/2013	Southern New Hampshire RPC
4/16/2013	City of Manchester – Board of Alderman
4/17/2013	City of Concord, New Hampshire
4/17/2013	Rockingham Planning Commission
4/17/2013	Town of Exeter, New Hampshire
4/17/2013	C&J Trailways
4/18/2013	Nashua RPC
4/18/2013	Town of Merrimack, New Hampshire
4/18/2013	Merrimack Chamber of Commerce
5/14/2013	Concord Chamber of Commerce
5/14/2013	NHDES
5/14/2013	PAC Meeting – Concord, New Hampshire
5/15/2013	Congresswoman Shea-Porter District Office
5/16/2013	FRA/FTA Conference Call
5/16/2013	Congresswoman Kuster District Office
5/16/2013	Manchester Chamber of Commerce
5/16/2013	Merrimack Valley Planning Commission
5/16/2013	Anagnost Companies
5/28/2013	Northern Middlesex Council of Governments
5/28/2013	PAR
5/30/2013	City of Dover, New Hampshire
6/5/2013	Public Meeting – Manchester, New Hampshire

Date	Stakeholder
6/28/2013	FTA
7/17/2013	MBTA
7/19/2013	Briefing for NHDOT Commissioner Clement
7/19/2013	PAR
7/23/2013	Land Use Workshop – Nashua, New Hampshire
7/23/2013	Land Use Workshop – Concord, New Hampshire
7/25/2013	Land Use Workshop – Manchester, New Hampshire
7/29/2013	EPA
8/19/2013	Congresswomen's Kuster and Shea-Porter's Staff Project Briefing/ Senator Shaheen's Staff Project Briefing/FRA Project Briefing – Washington, DC
11/20/2013	FTA/FRA – Washington, DC
12/17/2013	Central New Hampshire RPC
12/17/2013	City of Concord, New Hampshire
12/17/2013	City of Nashua, New Hampshire
12/17/2013	Nashua RPC
12/18/2013	City of Manchester, New Hampshire
12/18/2013	Southern New Hampshire Planning Commission
12/20/2013	FRA & FTA
1/21/2014	PAC Meeting – Concord, New Hampshire
1/31/2014	MassDOT/MBTA
2/06/2014	Boston Express
2/06/2014	MassDOT/NHDOT
3/03/2014	Commissioner Clement; Governor's staff
3/04/2014	Harry Blunt, Mark Sanborn; NHDOT Project Management
3/05/2014	Congresswoman Niki Tsongas' staff
3/05/2014	Public Scoping Meeting at NHDOT, Concord, New Hampshire
3/25/2014	FRA Conference call
3/26/2014	Manchester Board of Advisors Meeting
4/03/2014	Meeting with Amtrak Regarding Ridership Forecasting
4/15/2014	John D. (Jody) Ray (MBTA) and Chris Clement (NHDOT)
4/16/2014	NHDOT Natural Resource Coordination Meeting
4/17/2014	FTA – Cambridge, Massachusetts
4/22/2014	FRA Conference Call
4/25/2014	City of Nashua, New Hampshire – Tom Galligani, Economic Development Director
5/07/2014	NHDOT Commissioner and NHDOT Management
5/08/2014	Montagne Communications (NHRTA Public Relations firm)
6/04/2014	Meeting on Bow-Concord Project with NHDOT
5/14/2014	1st Hy-Rail trip with PAR
6/13/2014	FTA Meeting – Washington, DC
7/14/2014	Nashua RPC – Exit 36 SB Planning Study
7/1&28/2014	FRA Conference Calls
7/30/2014	2nd Hy-Rail Trip with PAR
8/06/2014	Mayor of the City of Nashua, New Hampshire
8/6/2014	Meeting with Chris Clement, selection of locally preferred alternative and State decision-making

Date	Stakeholder
8/6/2014	Meeting with Dan Kelly, development at Spit Brook Road
8/14/2014	FRA call, comments on deliverables
10/21/2014	FRA call with NHDOT Project Management
10/23/2014	Chris Kennedy, Governor's Transport Assistant
10/23/2014	FTA – Cambridge, Massachusetts
11/18/2014	PAC Meeting – Concord, New Hampshire
11/20/2014	Montagne Communications – EJ Powers
11/20/2014	Manchester Union Leader – Michael Cousineau
11/20/2014	Public Meeting – Nashua, New Hampshire
11/21/2014	Congresswoman Annie Kuster
11/21/2014	NHRTA

As a result of agency and stakeholder input, the following is a compilation of the most frequent comments and concerns:

- New Hampshire would benefit from a transportation system that provides multiple transit options, is less focused on single occupancy vehicles, and provides an increase in options that have the potential to ease traffic congestion and save commuting time.
- The Manchester-Boston Regional Airport is an important cog in the New Hampshire economy and a rail connection to the airport should be part of the Study.
- The state needs to work to attract and retain young professionals, who are now leaving New Hampshire at a faster rate than they are moving to the state.
- It is important to demonstrate the impacts and benefits of passenger rail to the state (economic, social, and environmental).
- The project needs to have a solid financial plan.
- State demographics are changing (the population is getting older), and the transportation system needs to address the needs of this changing demographic.
- The location of potential rail stations is important to many of the communities, and they would like to be part of the discussion in identifying appropriate locations.
- System safety needs to be analyzed.
- The fare structure for any system needs to be competitive with other forms of transportation.
- The frequency of operation needs to be competitive with other forms of transportation.
- The Study has many implications for development in New Hampshire, which needs to be quantified.
- Freight rail along the corridor is important, and the Study needs to examine the benefits to freight that could be realized by a passenger rail project.
- The project needs to quantify environmental impacts, including emissions, air quality, noise/vibration, etc.

- An increase in transit options has the potential to ease traffic congestion or slow the increase in traffic congestion in the state.
- Parking issues associated with potential rail stations is a concern in many communities.
- Any transportation study needs to include connections between rail/bus and other parts of the state, i.e., local transit systems.
- There is a concern among stakeholders that any proposed train service would negate the need for existing bus routes, which have been successful to date.
- A transparent process for the Study is important with a high-level of stakeholder and public engagement.
- Many stakeholders are interested in how passenger rail would impact the state's economy.

5.3 Website

A Study-specific website, http://www.nhcapitolcorridor.com, was developed to both disseminate and receive information about the Capitol Corridor AA Study.

5.4 Media Outreach

In cooperation with the NHDOT Public Information Office, notices of upcoming meetings were sent to the following local news media outlets:

- Print Media
  - Concord Monitor
  - Manchester Union Leader
  - Nashua Telegraph
  - Lawrence Eagle Tribune
- Broadcast Television
  - WBIN, Concord
  - WMUR, Manchester
  - TV 23, Manchester
  - TV 16, Nashua
- Radio
  - WEVO 89.1 FM, Concord
  - WGIR 610 AM, Manchester

5.5 Project Electronic Mailing List

A project electronic mailing list was developed with input from NHDOT, and maintained and used throughout the Study. Some individuals/organizations requested they be added to the list during public open houses, project briefings, or on the project website.

The mailing list is provided in Appendix H.

6 List of Preparers

The following individuals prepared technical portions of this EA:

- **URS Corporation**
  1155 Elm Street
  Manchester, New Hampshire
  - Russ Wilder, PG
  - Carl Chamberlin
  - Jim Cowan, INCE Bd. Cert.
  - Renee Ducker
  - Julia Suprock, AICP
  - Matthew Harris, RPA
  - Vanessa Zeoli
  - Eric Carlson
  - Sam Wang

- **Jacobs Engineering**
  343 Congress Street
  Boston, Massachusetts
  - David O. Nelson
  - Ryan Harris

- **Nobis Engineering**
  18 Chenell Drive
  Concord, New Hampshire
  - Michael Summerlin, PE
  - Stan Bonis, PG

- **Smart Environmental**
  72 North Main Street
  Concord, New Hampshire
  - Glenn Smart
  - Jennifer Riordan, CWS, CPESC

7 Distribution List

The following agencies, organizations, and persons received a copy of the EA:

Table 7.1: Distribution List

US Agencies/Officials	▪ **Federal Transit Administration** Noah Berger ▪ **Federal Railroad Administration** Trevor Gibson ▪ Fed**eral Highway Administration – New Hampshire Division** Jamie Sikora, Environmental Program Manager ▪ **United States Army Corps of Engineers New England District** Michael Hicks ▪ **United States Environmental Protection Agency, New England** Mark Kern Rosemary K. Monahan, PhD, Smart Growth Coordinator
State Agencies/ Officials	▪ **Massachusetts Executive Office of Energy and Environmental Affairs, MEPA Office** Deirdre Buckley, Director ▪ **Massachusetts Department of Environmental Protection** Stephen Johnson, Deputy Regional Director ▪ **Massachusetts Department of Transportation** John D. Ray, Deputy Director – Rail and Transit Division Ronald Morgan, MBTA Planning and Development Office ▪ **Massachusetts Historical Commission** Brona Simon ▪ **New Hampshire Department of Environmental Services** Timothy Drew, Public Information & Permit Administration Gino E. Infascelli, Water Pollution Division Lori Summer ▪ **New Hampshire Department of Transportation** Christine Perron, Senior Environmental Manager ▪ **New Hampshire Division of Historic Resources** Elizabeth Muzzey, Director ▪ **New Hampshire Fish and Game Department** Carol Henderson, Environmental Review Coordinator ▪ **New Hampshire Natural Heritage Bureau** Melissa Coppola, Environmental Information Specialist ▪ **MBTA** John D. Ray
Elected Officials	▪ **Massachusetts** Governor Deval Patrick Governor Elect Charles Baker Congresswoman, Niki Tsongas, Massachusetts 3rd Congressional District Senator Edward Markey ▪ **New Hampshire** Governor Maggie Hassan Senator Jeanne Shaheen Senator Kelly Ayotte Congresswoman Carol Shea Porter Congresswoman Annie Kuster

Regional Planning Commissioners	▪ **Boston Regional Metropolitan Planning Organization** Karl Quackenbush, Executive Director ▪ **Central New Hampshire Planning Commission** Michael Tardiff, Executive Director ▪ **Merrimack Valley Planning Commission** Joe Cosgrove, Environmental Program Manager Anthony Komornick, Transportation Program Manager ▪ **Nashua Regional Planning Commission** Kerry Diers, Executive Director Tim Roache, Assistant Director ▪ **Northern Middlesex Council of Governments** Beverly A. Woods, Executive Director ▪ **Rockingham Planning Commission** Cliff Sinnott, Executive Director ▪ **Southern New Hampshire Planning Commission** David Preece, Executive Director
City and Town Officials	▪ **City of Concord** Mayor Jim Bouley Carlos P. Baia, Deputy City Manager ▪ **City of Manchester** Mayor Ted Gatsas William Craig, Director of Economic Development ▪ **City of Nashua** Mayor Donnalee Lozeau Thomas Galligani, Economic Development Division Director
City Agencies	▪ **Greater Concord Chamber of Commerce** Timothy G. Sink, CCE President ▪ **Greater Manchester Chamber of Commerce** Michael J. Skelton, President & CEO ▪ **Greater Nashua Chamber of Commerce** Christopher Williams ▪ **Manchester-Boston Regional Airport** Mark P. Brewer, A.A.E Director
Interest Groups	▪ **Appalachian Mountain Club** John Judge, President ▪ **Boston Express/Concord Coach** Ben Blount ▪ **Conservation Law Foundation** Tom Irwin, Vice President ▪ **New Hampshire Sierra Club** Catherine Corkey, Director ▪ **Society of the Protection of New Hampshire Forests** Jane A. Difley, President/Forester

APPENDIX A Emissions Calculations (Upon Request)

Acronym	
ADT	average daily traffic
CAA	Clean Air Act
CAFÉ	Corporate Average Fuel Economy
CEQ	Council on Environmental Quality
CH_4	methane
CO	carbon monoxide
CO_2	carbon dioxide
CO_2e	carbon dioxide equivalent
DPM	diesel particulate matter
GHG	greenhouse gasses
GWP	global warming potential
HAPs	hazardous air pollutants
HFCs	hydrofluorocarbons
LOS	level of service
MA	Massachusetts
MassDEP	Massachusetts Department of Environmental Protection
MMT	million metric tons
MSAT	mobile source air toxic
NEPA	National Environmental Policy Act
NESHAP	National Emission Standards for Hazardous Air Pollutants
NH	New Hampshire
NHDES	New Hampshire Department of Environmental Services
NHTSA	National Highway Traffic Safety Administration
N_2O	nitrous oxide
NOA	naturally occurring asbestos
NAAQS	National Ambien Air Quality Standards
NO_x	nitrogen oxides
O_3	ozone
Pb	lead
PFCs	perfluorocarbons
PM_{10}	particulate matter up to 10 micrometers in diameter
$PM_{2.5}$	particulate matter up to 2.5 micrometers in diameter
POM	polycyclic organic matter
ppm	parts per million
RAQS	regional air quality strategy
SF_6	sulfur hexafluoride
SIP	state implementation plan
SO_2	sulfur dioxide

TAC	toxic air contaminant
TSP	total suspended particulate
USEPA	United States Environmental Protection Agency
VMT	Vehicle miles traveled
VOC	volatile organic compound

SECTION 1 REGULATORY CONTEXT

1.1 POLLUTANTS

Ozone. Ozone (O_3) occurs in two layers of the atmosphere. The layer surrounding the earth's surface is the troposphere. Here, ground level O_3 is an air pollutant that damages human health, vegetation, and many common materials. It is a key ingredient of urban smog. The troposphere extends to a level about 10 miles up, where it meets the second layer, the stratosphere. In contrast, the beneficial or stratospheric O_3 layer extends upward from about 10 to 30 miles and protects life on earth from the sun's harmful ultraviolet rays.

Ground level O_3 is what is known as a photochemical pollutant. Significant O_3 formation generally requires an adequate amount of precursors in the atmosphere and several hours in a stable atmosphere with strong sunlight for the photochemical reaction to take place.

Ozone is a regional air pollutant. It is generated over a large area and is transported and spread by wind. O_3, the primary constituent of smog, is the most complex, difficult to control, and the most pervasive of the criteria pollutants. Unlike other pollutants, O_3 is not emitted directly into the air by specific sources. O_3 is created by sunlight acting on precursors pollutants, specifically nitrogen oxides (NO_x) and volatile organic compounds (VOCs). Sources of precursor gases to the photochemical reaction that form O_3 number in the thousands. Common sources include consumer products, gasoline vapors, chemical solvents, and combustion products of various fuels. Originating from gas stations, motor vehicles, large industrial facilities, and small businesses such as bakeries and dry cleaners, the O_3 forming chemical reactions often take place in another location, catalyzed by sunlight and heat. High O_3 concentrations can form over large regions when emissions from motor vehicles and stationary sources are carried hundreds of miles from their origins.

Particulates. Particulates in the air are caused by a combination of: 1) windblown fugitive dust or road dust; 2) particles emitted directly from combustion sources; and 3) organic, sulfate, ammonium, and nitrate aerosols formed in the air from emitted hydrocarbons, sulfur oxides, ammonia, and nitrogen oxides. Respirable particulate matter is referred to as PM_{10}, which has a diameter of 10 micrometers or less. It can contribute to increased respiratory disease, lung damage, cancer, premature death, as well as reduced visibility and surface soiling. In 1987, the United States Environmental Protection Agency (USEPA) adopted standards for PM_{10} and phased out the previous standards for total suspended particulate (TSP) that had been in effect.

Fine particulates result from fuel combustion in motor vehicles and industrial sources, residential and agricultural burning, and from atmospheric reactions involving NO_X, SO_X, and organics. Fine particulates are referred to as $PM_{2.5}$ and have a diameter equal to or less than 2.5 micrometers. The potential health effects of $PM_{2.5}$ are considered potentially more serious than those of PM_{10}. In 1997, USEPA established the first annual and 24-hour National Ambient Air

Quality Standards (NAAQS) for $PM_{2.5}$. The standard regulating the 3-year average of the 98th percentile of 24-hour PM_{10} concentrations, or the monitored design value (35µg/m^3), became effective on December 17, 2006.

Carbon Monoxide. CO is a product of incomplete combustion of fuels that contain carbon, principally from automobiles and other mobile sources of pollution, but also from stationary combustion sources. In cities, automobile exhaust can cause as much as 95 percent of all CO emissions. These emissions can result in high concentrations of CO, particularly in local areas with heavy traffic congestion. CO emissions from wood-burning stoves and fireplaces can also be important sources of this pollutant. Health effects resulting from exposure to high CO levels can include chest pain in heart patients, headaches, and reduced mental alertness.

Nitrogen Dioxide. Nitrogen oxide emissions are primarily generated from the combustion of fuels in air. Nitrogen oxides include NO and NO_2. Because NO reacts to form NO_2 in the atmosphere over time and NO_2 has been demonstrated to cause the more adverse health effects such as lung irritation and damage, NO_2 is the listed criteria pollutant. The control of NO_2 is also important because it contributes to the atmospheric formation of ozone, the principal component of smog, and the formation of nitrates which contribute to fine particle formation.

Sulfur Dioxide. SO_2 is produced when any sulfur-containing fuel is burned. It is also emitted by chemical plants that treat or refine sulfur or sulfur-containing chemicals. Natural gas contains trace quantities of sulfur, while fuel oils contain much larger amounts. SO_2 can increase lung disease and breathing problems for asthmatics. It reacts in the atmosphere to form acid rain, which is destructive to crops and vegetation, as well as to buildings, materials, and works of art. It also contributes to the formation of fine particulate sulfates.

Lead (Pb). Lead exposure can occur through multiple pathways, including inhalation of air and ingestion of lead in food caused by water, soil, or dust contamination. Excessive exposure to lead can trigger seizures, mental retardation or behavioral disorders, and other central nervous system damage. Lead gasoline additives, nonferrous smelters, and battery manufacturing plants were the most significant contributors to atmospheric lead emissions. Legislation in the early 1970s required gradual reduction of the lead content of gasoline over a period of time, which has dramatically reduced lead emissions from mobile and other combustion sources. These controls have essentially eliminated violations of the lead standard for ambient air in urban areas.

Asbestos. Asbestos deposits from brake wear may be present on surfaces and in the ambient air along the corridor alignment. In addition, asbestos-containing materials may have been used in constructing buildings that will be demolished. Chronic inhalation exposure to asbestos in humans can lead to a lung disease called asbestosis, which is a diffuse fibrous scarring of the lungs. Symptoms of asbestosis include shortness of breath, difficulty in breathing, and coughing. Asbestosis is a progressive disease (i.e., the severity of symptoms tends to increase with time, even after the exposure has stopped). In severe cases, this disease can lead to death due to

impairment of respiratory function. A large number of occupational studies have reported that exposure to asbestos by inhalation can cause lung cancer and mesothelioma, which is a rare cancer of the membranes lining the abdominal cavity and surrounding internal organs. USEPA considers asbestos to be a human carcinogen.

Mobile Source Air Toxics (MSAT) **–** USEPA has assessed this expansive list in their latest rule on the Control of Hazardous Air Pollutants (HAPs), also known as air toxics, from Mobile Sources and identified a group of 93 compounds emitted from mobile sources that are listed in their Integrated Risk Information System. The MSAT rules are intended to reduce HAPs emitted by cars and trucks. USEPA identified seven compounds with significant contributions from mobile sources that are among the national- and regional-scale cancer risk drivers from its National Air Toxics Assessment (USEPA 1999). These are acrolein, benzene, 1,3-butadiene, diesel particulate matter (DPM) plus diesel exhaust organic gases, formaldehyde, naphthalene, and polycyclic organic matter (POM). This list, however, is subject to change and may be adjusted in consideration of future USEPA rules.

Greenhouse Gases and Climate Change. Gases that trap heat in the atmosphere are often called greenhouse gases (GHGs). This layer of gases functions much the same as glass in a greenhouse (i.e., both prevent the escape of heat), which is why this phenomenon is known as the "greenhouse effect." The greenhouse effect helps to regulate the temperature of the Earth and is essential for life and other natural processes. The greenhouse effect is the result of heat absorption by GHGs and downward re-radiation of some of that heat. The concern is not with the fact that we have a greenhouse effect, but whether human activities are leading to an enhancement of the greenhouse effect by the emission of GHGs through fossil fuel combustion and reduced uptake of GHGs through deforestation. A large body of evidence, accumulated over several decades from hundreds of studies, supports the conclusion that human activity is the primary driver of recent warming (National Climatic Data Center, 2012).

Some GHGs such as carbon dioxide (CO_2) occur naturally and are emitted to the atmosphere through natural processes such as volcanoes, forest fires, and biological processes. Other GHGs (e.g., fluorinated gases) are created and emitted solely through human activities. The principal GHGs that enter the atmosphere because of human activities are carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6). The sources of these emissions associated with human activities are:

Carbon Dioxide – Carbon dioxide can enter the atmosphere through the burning of fossil fuels, solid waste, trees and wood products, and as a result of other chemical reactions (e.g., manufacture of cement).

Methane – Methane is emitted during the production and transport of coal, natural gas, and oil. Methane emissions also result from livestock and other agricultural practices and by the decay of organic waste in municipal solid waste landfills.

Nitrous Oxide – Nitrous oxide is emitted during agricultural and industrial activities, as well as during combustion of fossil fuels and solid waste.

Synthetic GHGs – Hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride are synthetic, powerful GHGs that are emitted from a variety of industrial processes. For example, sulfur hexafluoride is used in magnesium processing, semiconductor manufacturing, and electrical transmission equipment (circuit breakers), as well as a tracer gas for leak detection. Fluorinated gases are sometimes used as substitutes for ozone-depleting substances (e.g., CFCs, HCFCs, and halons). These gases are typically emitted in smaller quantities, but because they are potent GHGs, they are sometimes referred to as high Global Warming Potential gases.

The Global Warming Potential (GWP) of each GHG is the ability of that gas to trap heat in the atmosphere relative to CO_2. Total GHG emissions are expressed as carbon dioxide equivalent (CO_2e) and are the sum of the GWP-weighted emissions of each GHG.

Climate change refers to any significant change in measures of climate, such as average temperature, precipitation, or wind patterns over a period of time. Climate change may result from natural processes and human activities that change the composition of the atmosphere and alter the surface and features of the land. Significant changes in global climate patterns have recently been associated with global warming, a worldwide average increase in the temperature of the atmosphere near the Earth's surface, attributed to accumulation of GHG emissions in the atmosphere.

1.2 NAAQS AND STATE STANDARDS

USEPA, in response to the federal Clean Air Act (CAA) of 1970, established National Ambient Air Quality Standards (NAAQS) in Title 40 CFR Part 50. The NAAQS include both primary and secondary standards for six "criteria pollutants." These criteria pollutants are O_3, CO, NO_2, SO_2, particulate matter, and lead. Primary standards were established to protect human health, and secondary standards were designed to protect property and natural ecosystems from the effects of air pollution.

The 1990 CAA Amendments established attainment deadlines for all designated areas that were not in attainment with the NAAQS. In addition to the NAAQS described above, a new federal standard for $PM_{2.5}$ and a revised O_3 standard were promulgated in July 1997. The new federal standards were challenged in a court case during 1998. The court required revisions in both standards before USEPA can enforce them. The U.S. Supreme Court upheld an appeal of the District Court decision in February 2001. These issues were resolved and the 1-hour O_3 standard revoked in 2005, while the revised $PM_{2.5}$ standard was made effective in 2006. In 2010 a new 1-hour SO_2 standard was implemented and the SO_2 24-hour and annual standards were revoked. The 3-hour secondary standard for SO_2 remains unchanged. The NAAQS relevant to the Project are summarized in Table 1.

TABLE 1
NATIONAL AMBIENT AIR QUALITY STANDARDS

Pollutant [final rule cite]		Primary/ Secondary	Averaging Time	Level	Form
Carbon Monoxide [76 FR 54294, Aug 31, 2011]		primary	8-hour	9 ppm	Not to be exceeded more than once per year
			1-hour	35 ppm	
Lead [73 FR 66964, Nov 12, 2008]		primary and secondary	Rolling 3 month average	0.15 µg/m^3 (1)	Not to be exceeded
Nitrogen Dioxide [75 FR 6474, Feb 9, 2010] [61 FR 52852, Oct 8, 1996]		primary	1-hour	100 ppb	98th percentile of 1-hour daily maximum concentrations, averaged over 3 years
		primary and secondary	Annual	53 ppb (2)	Annual Mean
Ozone [73 FR 16436, Mar 27, 2008]		primary and secondary	8-hour	0.075 ppm (3)	Annual fourth-highest daily maximum 8-hr concentration, averaged over 3 years
Particle Pollution Dec 14, 2012	$PM_{2.5}$	primary	Annual	12 µg/m^3	annual mean, averaged over 3 years
		secondary	Annual	15 µg/m^3	annual mean, averaged over 3 years
		primary and secondary	24-hour	35 µg/m^3	98th percentile, averaged over 3 years
	PM_{10}	primary and secondary	24-hour	150 µg/m^3	Not to be exceeded more than once per year on average over 3 years
Sulfur Dioxide [75 FR 35520, Jun 22, 2010] [38 FR 25678, Sept 14, 1973]		primary	1-hour	75 ppb (4)	99th percentile of 1-hour daily maximum concentrations, averaged over 3 years
		secondary	3-hour	0.5 ppm	Not to be exceeded more than once per year

Notes:
(1) Final rule signed October 15, 2008. The 1978 lead standard (1.5 µg/m3 as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.
(2) The official level of the annual NO2 standard is 0.053 ppm, equal to 53 ppb, which is shown here for the purpose of clearer comparison to the 1-hour standard.
(3) Final rule signed March 12, 2008. The 1997 ozone standard (0.08 ppm, annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years) and related implementation rules remain in place. In 1997, USEPA revoked the 1-hour ozone standard (0.12 ppm, not to be exceeded more than once per year) in all areas, although some areas have continued obligations under that standard ("anti-backsliding"). The 1-hour ozone standard is attained when the expected number of days per calendar year with maximum hourly average concentrations above 0.12 ppm is less than or equal to 1.
(4) Final rule signed June 2, 2010. The 1971 annual and 24-hour SO2 standards were revoked in that same rulemaking. However, these standards remain in effect until one year after an area is designated for the 2010 standard, except in areas designated nonattainment for the 1971 standards, where the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standard are approved.
ppm – parts per million (unit of measure for gases only)
ppb – parts per billion (unit of measure for gases only)
µg/m^3 – micrograms per cubic meter (unit of measure for gases and particles, including lead)

USEPA, Massachusetts Department of Environmental Protection (MassDEP), and New Hampshire Department of Environmental Services (NHDES) determine air quality attainment status by comparing local ambient air quality measurements from the state or local ambient air monitoring stations with the NAAQS. Those areas that meet ambient air quality standards are classified as "attainment" areas; areas that do not meet the standards are classified as "non-attainment" areas. Areas that have insufficient air quality data may be identified as

unclassifiable areas. These attainment designations are determined on a pollutant-by-pollutant basis. The Project area is classified as attainment with respect to the NAAQS for O_3, NO_2, PM_{10}, $PM_{2.5}$, SO_2, and CO, except for some areas in Massachusetts are maintenance areas for CO (1971 standard) and nonattainment area for ozone (1997 standard) and some areas in New Hampshire are nonattainment area for SO_2 (2010 standard) and maintenance area for CO (1997 standard). Nitrogen dioxide (NO_2) and SO_2 are regulated as PM_{10} precursors, and NO_2 and VOCs as O_3 precursors. Table 2 presents the attainment status for Massachusetts and New Hampshire.

TABLE 2
ATTAINMENT STATUS IN MASSACHUSETTS AND NEW HAMPSHIRE

Area	Pollutant	Attainment Status
MA – Boston and Lowell	CO (1971 standard)	Maintenance
MA – Boston-Lawrence-Worcester	Ozone (1997 standard)	Nonattainment - Moderate
NH – Hillsborough County	CO (1971 standard)	Maintenance
NH – Central New Hampshire	Sulfur Dioxide (2010 standard)	Nonattainment
NH – Boston-Manchester-Portsmouth	Ozone (1997 standard)	Maintenance

Notes: The NH and MA areas that are not listed here are all in attainment for all pollutants.
NH = New Hampshire
MA = Massachusetts

1.3 FEDERAL CONFORMITY RULES

Pursuant to CAA Section 176(c) requirements, USEPA promulgated Title 40 of the Code of Federal Regulations Part 51 (40 Code of Federal Regulations [CFR] 51) Subpart W and 40 CFR Part 93, Subpart B, ―Determining Conformity of General Federal Actions to State or Federal Implementation Plans (see 58 Fed. Reg. 63214 [November 30, 1993], as amended, 75 Fed. Reg. 17253 [April 5, 2010]). These regulations, commonly referred to as the General Conformity Rule, apply to all federal actions including those by Federal Railroad Administration (FRA), except for those federal actions which are excluded from review (e.g., stationary source emissions) or related to transportation plans, programs, and projects under Title 23 U.S. Code or the Federal Transit Act, which are subject to Transportation Conformity.

40 CFR Part 51, Subpart W, applies in states where the state has an approved state implementation plan (SIP) revision adopting General Conformity regulations; 40 CFR Part 93, Subpart B, applies in states where the state does not have an approved SIP revision adopting General Conformity regulations.

The General Conformity Rule is used to determine if federal actions meet the requirements of the CAA and the applicable SIP by ensuring that air emissions related to the action do not:

- Cause or contribute to new violations of a NAAQS
- Increase the frequency or severity of any existing violation of a NAAQS
- Delay timely attainment of a NAAQS or interim emission reduction

A conformity determination under the General Conformity Rule is required if the federal agency determines that the action will occur in a nonattainment or maintenance area; one or more specific exemptions do not apply to the action; the action is not included in the federal agency's ―presumed to conform list; the emissions from the proposed action are not within the approved emissions budget for an applicable facility; and the total direct and indirect emissions of a pollutant (or its precursors), are at or above the *de minimis* levels established in the General Conformity regulations (75 Fed. Reg. 17255). Table 3 presents the applicable *de minimis* emissions levels for this Project.

TABLE 3
GENERAL CONFORMITY *de minimis* LEVELS

Pollutant	Federal Attainment Status	Threshold Values (tpy)
Ozone	Nonattainment – Moderate Maintenance	100 for each precursor (NO_x and VOC)
SO_2	Nonattainment	100
CO	Maintenance	100

Notes:
typ = ton per year

Conformity regulatory criteria are listed in 40 CFR 93.158. An action will be required to conform to the applicable SIP if, for each pollutant that exceeds the *de minimis* emissions level in 40 CFR 93.153(b) or otherwise requires a conformity determination due to the total of direct and indirect emissions from the action, the action meets the requirements of 40 CFR 93.158(c).

In addition, federal activities may not cause or contribute to new violations of air quality standards, exacerbate existing violations, or interfere with timely attainment or required interim emissions reductions toward attainment. The proposed project is subject to review under the USEPA General Conformity Rule.

1.4 GHG REGULATIONS/STANDARDS

Climate change and greenhouse gas (GHG) emission reductions are a concern at the federal level. Laws and regulations, as well as plans and policies, address global climate change issues. This section summarizes key federal regulations relevant to the project.

In Massachusetts v. U.S. Environmental Protection Agency, et al., 549 U.S. 497 (2007), the United States Supreme Court ruled that GHG does fit within the CAA definition of a pollutant and that USEPA has the authority to regulate GHG.

On September 22, 2009, USEPA published the final rule that requires mandatory reporting of GHG emissions from large sources in the United States. The rule amends CAA Regulations under 40 CFR Parts 86, 87, 89 90 and 94 and provides a new section, Part 98. USEPA uses the reports to collect accurate and comprehensive emissions data that can inform future policy decisions. Facilities that emit 25,000 metric tons or more per year of GHG emissions must submit annual reports to USEPA under Subpart C of the final rule. GHGs covered by the final rule are carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF_6), and other fluorinated gases including nitrogen trifluoride (NF3) and hydrofluorinated ethers (HFEs). This is not a transportation-related regulation. However, the methodology developed as part of this regulation is helpful in identifying potential GHG emissions.

On October 5, 2009, President Obama signed Executive Order (E.O.) 13514; Federal Leadership in Environmental, Energy, and Economic Performance. E.O. 13514 requires Federal agencies to set a 2020 GHG emission-reduction target within 90 days, increase energy efficiency, reduce fleet petroleum consumption, conserve water, reduce waste, support sustainable communities, and leverage federal purchasing power to promote environmentally responsible products and technologies.

On December 7, 2009, the Final Endangerment and Cause or Contribute Findings for Greenhouse Gases (endangerment finding), under Section 202(a) of the CAA, went into effect. The endangerment finding states that current and projected concentrations of the six key well-mixed GHGs in the atmosphere (CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6) threaten the public health and welfare of current and future generations. Furthermore, it states that the combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG pollution, which threatens public health and welfare (USEPA 2010a).

Based on the endangerment finding, USEPA is revising vehicle emission standards under the CAA. USEPA and National Highway Traffic Safety Administration (NHTSA) updated the Corporate Average Fuel Economy (CAFE) fuel standards on May 7, 2010 (75 Fed. Reg. 25324), requiring substantial improvements in fuel economy for all vehicles sold in the Unites States. The new standards apply to new passenger cars, light-duty trucks, and medium-duty passenger

vehicles, covering model years 2012 through 2016. The USEPA GHG standards require these vehicles to meet an estimated combined average emissions level of 250 grams of CO_2 per mile in the model year 2016, which would be the equivalent to 35.5 miles per gallon if the automotive industry were to meet this CO_2 level solely through fuel economy improvements.

On September 15, 2011, USEPA and NHTSA issued a Final Rule of Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles (76 Fed. Reg. 57107). This final rule is tailored to each of the three regulatory categories of heavy-duty vehicles: combination tractors, heavy-duty pickup trucks and cars, and vocational vehicles. USEPA and NHTSA estimated that the new standards in this rule will reduce CO_2 emissions by approximately 270 million metric tons (MMT) and save 530 million barrels of oil over the life of vehicles sold during the 2014 through 2018 model years.

On February 18, 2010, the White House Council on Environmental Quality (CEQ) released draft guidance regarding the consideration of GHG in National Environmental Policy Act (NEPA) documents for federal actions. The draft guidelines include a presumptive threshold of 25,000 metric tons of carbon dioxide equivalent (CO2e) emissions from a proposed action to trigger a quantitative analysis. CEQ has not established when GHG emissions are ―significant for NEPA purposes; rather, it poses the question to the public (CEQ 2010).

SECTION 2 METHODOLOGY

2.1 LOCAL IMPACT (MICRO-SCALE ANALYSIS)

On a local scale, the potential effect of the Project on air quality is limited to increases in locomotive emissions, and both increases and decreases in on-road emissions. Decreases in on-road emissions could have a beneficial impact on local air quality if large numbers of vehicle trips are shifted to rail, occurring along roadways where those trips would otherwise occur. Since the details of that shift are not clearly known at this time, this potential benefit has not been analyzed; however, a more meaningful analysis of the region-wide benefits of this mode shift is included in the regional analysis.

Mobile source dispersion models are the basic analytical tools used to estimate hotspot concentrations expected under given traffic, roadway geometry, and meteorological conditions. However, quantitative CO hotspot and PM hotspot analyses for this project are not required in this Service-Level impact analysis report because the project is located in either federal attainment or federal maintenance areas for those pollutants. Therefore, dispersion modeling was not used for the project. The project is subject to the general conformity guidelines but not the transportation conformity guidelines. Therefore, the micro-scale analysis focuses on the potential local effect associated with increases in locomotive emissions.

Locomotive emissions factors were obtained from USEPA 2009 technical highlights for locomotive emissions. The total emissions were distributed to each State and by attainment areas.

2.2 REGIONAL IMPACT (MESO-SCALE ANALYSIS)

2.2.1 Criteria Pollutants

The regional impact (meso-scale emissions analysis) estimates the net change in emissions associated with the entire project, including the change in both on-road and locomotive emissions for the two project alternatives, Manchester Regional Commuter Rail and Intercity 8. The locomotive emission factors used are described in the local impact (micro-scale analysis) section above. An on-road vehicle emission analysis was also conducted using average daily vehicle miles traveled (VMT) estimates and associated average daily speed estimates for each affected area. The criteria pollutant emission factors for on-road vehicles were obtained using the USEPA MOVES emissions model. For the Service Level analysis, the MOVES model was ran at the national scale with national input data allocated to Hillsborough and Merrimack counties in New Hampshire. Total vehicle miles-traveled (VMT) were obtained from the project traffic study. The analysis was conducted for the modeling year 2020.

To determine overall pollutant burdens generated by on-road vehicles, estimated VMT increases or decreases were multiplied by applicable pollutant's emission factors, which are based on national default speeds and vehicle speciation data, and using a 2020 analysis year.

2.2.2 Hazardous Air Pollutants, Greenhouse Gases, and Other Pollutants

The federal Clean Air Act (CAA) Amendments of 1990 listed 188 Hazardous Air Pollutants (HAPs) and addressed the need to control toxic emissions from transportation. USEPA's 2007 Mobile Source Air Toxics (MSAT) rule identified a subset of seven HAPs as having significant contributions from mobile sources: benzene, 1,3-butadiene, formaldehyde, acrolein, naphthalene, polycyclic organic matter (POM), and diesel particulate matter (DPM).

Based on the FHWA guidance, the proposed alternatives do not require a detailed quantitative analysis. In addition, the detailed project level MSAT and GHG emission factors for vehicles and locomotives were not available. Therefore, the hazardous air pollutant and the greenhouse gases emissions were estimated by scaling either NO_x emissions from the MOVES model, SO_2 emissions from locomotive engines, or NO_x emissions from USEPA's 2011 National Emissions Inventory data.

Asbestos minerals occur in rocks and soil as the result of natural geologic processes. Naturally occurring asbestos (NOA) takes the form of long, thin, flexible, separable fibers. Natural weathering or human disturbance can break NOA down to microscopic fibers, easily suspended in air. When inhaled, these thin fibers irritate tissues and resist the body's natural defenses. In

addition, asbestos-containing materials may have been used in constructing buildings that would be demolished. The demolition of asbestos-containing materials is subject to the limitations of the National Emission Standards for Hazardous Air Pollutants (NESHAP) regulations and would require an asbestos inspection. The asbestos survey would be conducted before any construction activity starts.

SECTION 3 EXISTING CONDITIONS

Ambient air quality standards have been set by both the federal government and the Commonwealth of Massachusetts to protect public health and welfare with an adequate margin of safety. However, according to the MassDEP, the state does not designate areas as attainment or nonattainment with these standards. Pollutants for which NAAQS have been established are often referred to as "criteria" air pollutants. This term is derived from the comprehensive health and damage effects review that culminates in pollutant-specific air quality criteria documents, which precede the establishment of NAAQS. These standards are reviewed on a legally prescribed frequency and revised as warranted by new health and welfare effects data. Each NAAQS is based on a specific averaging time over which the concentration is measured. Different averaging times are based upon protection against short-term, high-dosage effects or longer-term, low-dosage effects. Most NAAQS may be exceeded no more than once per year. A listing of the current NAAQS is provided in Section 1.2, NAAQS and State Standards.

The ambient air quality in the project area is monitored at a number of permanent air quality monitoring stations operated by USEPA, MassDEP, and NHDES. The monitoring stations within Massachusetts that are closest to the Project area are in Chelmsford, Lawrence, and Boston (Charlestown, North End, Kenmore Square, and Roxbury). In New Hampshire the monitoring stations nearest to the Project area are in Nashua (Gilson Road and Crown Street), Concord, Peterborough, and Manchester. For each pollutant, the maximum concentration from these stations was selected as a conservative background concentration level. Background concentration data is presented in Tables 4 to Table 9.

TABLE 4
CONCENTRATION DATA SUMMARY FOR OZONE

State	Year	Highest Concentration for O_3 (ppm)		Number of Days Exceeding Standards	
		1-hour	8-hour	1-hr	8-hr
Massachusetts	2011	0.103	0.086	0	1
	2012	0.113	0.089	0	1
	2013	0.082	0.071	0	0
New Hampshire	2011	0.108	0.09	0	1
	2012	0.112	0.085	0	2
	2013	0.081	0.07	0	0

Notes:
ppm = parts per million

MA data from the Chelmsford monitor.

NH data from the Nashua (Gilson Road) monitor.

TABLE 5
CONCENTRATION DATA SUMMARY FOR NITROGEN DIOXIDE

State	Year	Highest 1-hour Concentration for NO_2 (ppm)	98th Percentile 1-hour Concentration for NO_2 (ppm)	Number of Days Exceeding Standards (days)
Massachusetts	2011	75	53	0
	2012	61	49	0
	2013	56	48	0
New Hampshire	2011	0.012	0.01	0
	2012	0.011	0.01	0
	2013	0.009	0.009	0

Notes:

MA data from the Boston (Kenmore Square) monitor.

SECTION 4 ENVIRONMENTAL CONSEQUENCES

4.1 LOCAL ANALYSIS RESULTS

The results of the micro-scale analysis are presented in Table 10 and Table 11. The results represent the local impact from locomotive emissions along the track and at stations for both Manchester Regional Commuter Rail and Intercity 8 alternatives.

TABLE 10
LOCAL AIR QUALITY IMPACT FROM LOCOMOTIVES
(MANCHESTER REGIONAL COMMUTER RAIL ALTERNATIVE)

Annual Emissions (tons/year)	CO	NO_x	PM_{10}	$PM_{2.5}$	SO_2	VOC
MA total	1.78	11.93	0.44	0.43	0.01	0.70
Boston and Lowell 1997 Ozone Nonattainment area and 1971 CO Maintenance area	1.05	7.05	0.26	0.25	0.00	0.41
NH - Service to Nashua only	2.49	16.76	0.62	0.60	0.01	0.98
NH - Service from Nashua to Manchester	1.58	10.65	0.40	0.38	0.01	0.63
NH total - includes Central NH SO2 NAA, 1971 CO maintenance area, and 1997 Ozone maintenance area	4.08	27.40	1.02	0.99	0.01	1.61
Idling emissions	0.04	0.29	0.01	0.01	0.00	0.02
Applicable General Conformity Emission *de minimis* level (to each nonattainment or maintenance area)	100	100	NA	NA	100	100
Exceed *de minimis* level?	No	No	NA	NA	No	No

Notes:
NA = Not Applicable
NAA = nonattainment area
NH = New Hampshire
MA = Massachusetts

TABLE 11
LOCAL AIR QUALITY IMPACT FROM LOCOMOTIVES (INTERCITY 8 ALTERNATIVE)

Annual Emissions (tons/year)	CO	NO_x	PM_{10}	$PM_{2.5}$	SO_2	VOC
MA total	3.22	21.67	0.81	0.78	0.01	1.27
Boston and Lowell 1997 Ozone Nonattainment area and 1971 CO Maintenance area	0.77	5.21	0.19	0.19	0.00	0.31
NH total - includes Central NH SO2 NAA, 1971 CO maintenance area, and 1997 Ozone maintenance area	3.87	26.03	0.97	0.94	0.01	1.53
Idling emissions	0.03	0.19	0.01	0.01	0.00	0.01
Applicable General Conformity Emission *de minimis* level (to each nonattainment or maintenance area)	100	100	NA	NA	100	100
Exceed *de minimis* level?	No	No	NA	NA	No	No

Notes:
NA = Not Applicable
NAA = nonattainment area
NH = New Hampshire
MA = Massachusetts

Since mobile source dispersion modeling and hotspot analyses are not required for this Service Level analysis project, the results of the micro-scale emissions presented in Table 10 and Table 11 show that project emissions are below the federal general conformity *de minimis* levels for all applicable criteria pollutants in each nonattainment or maintenance area in New Hampshire and Massachusetts. Therefore, the local air quality impact is not significant due to Project operations.

4.2 REGIONAL ANALYSIS RESULTS

4.2.1 Criteria Pollutant Results

The total net change in criteria pollutant emissions in the project's affected region from the Manchester Regional Commuter Rail Alternative and Intercity 8 Alternative are presented in Table 12 and 13, respectively. There will be emissions reductions for all criteria pollutants in both alternatives except for PM_{10}, $PM_{2.5}$, NO_x, and VOC in Intercity 8 Alternative. However, the net emissions increases for those pollutants in Intercity 8 Alternative are definitely below the federal general conformity *de minimis* levels since there are some emissions reductions from the saving of vehicle trips. Therefore, in either alternative the project is presumed to conform to the applicable SIPs and would not require a full conformity analysis and conformity determination.

TABLE 12
REGIONAL AIR QUALITY IMPACT – CRITERIA POLLUTANTS
(MANCHESTER REGIONAL COMMUTER RAIL ALTERNATIVE)

Emissions Increases (ton/year)	CO	NO_x	PM_{10}	$PM_{2.5}$	SO_2	VOC

4.2.2 Hazardous Pollutant Emissions Results

The total net change in HAPs emissions in the project's affected region from the Manchester Regional Commuter Rail Alternative and Intercity 8 Alternative are presented in Table 14 and Table 15, respectively. Lead emissions were also estimated using light-duty vehicle emissions. DPM emissions are conservatively assumed to be the same as the $PM_{2.5}$ emissions in Table 12 and Table 13.

USEPA regulations for vehicle engines and fuels will cause overall MSAT emissions to decline significantly over the next several decades in three ways: (1) by lowering the benzene content in gasoline; (2) by reducing exhaust emissions from passenger vehicles operated at cold temperatures; and (3) by reducing emissions that evaporate from, and permeate through, portable fuel containers. Federal regulations are also severely reducing the diesel emissions from both on-road and non-road vehicles, and diesel PM is therefore also expected to diminish over time. In general, the impacts are expected to be much lower than those presented in Table 12 and Table 13.

4.2.3 Greenhouse Gas Results

The estimated annual operational emissions increases in GHG emissions associated with the Manchester Regional Commuter Rail and Intercity 8 alternatives are presented in Table 16 and Table 17, respectively. Manchester Regional Commuter Rail Alternative has much greater emission reductions in total potential greenhouse gases and climate change impact than the Intercity 8 Alternative.

The New Hampshire 10-year State Energy Strategy from the New Hampshire Office of Energy & Planning Department in September 2014 also supported to use rail as one of the major energy

saving strategies for the State. It recommended to maintain and to expand rail use instead of all freight option.

SECTION 5 POTENTIAL MITIGATION STRATEGIES

Since global climate change is caused cumulatively by world-wide activity, the impact of a specific program on climate change cannot be determined. Therefore, the approach applied here for evaluating the potential impact of the program is to identify the program's potential GHG emissions, and to evaluate whether it incorporates cost-effective energy efficiency and renewable energy measures into its design, construction, and operation to the maximum extent practicable, consistent with social, economic and other essential considerations. By doing so, the program would demonstrate consistency with state and local policies.

Since this is a Service-Level impact analysis, the details of design, construction, and operation are not yet fully available. Therefore, this section identifies potential measures for inclusion, which would reduce the program's energy and GHG footprint if implemented. These measures will be further investigated, and if found to be practicable, incorporated in the program's design and operation.

Operational

Shift Locomotives Engines to Higher Tier 1's or to Change the Fuel to Biodiesel Fuel—Options to use biodiesel for the locomotives will be investigated, including blends of B20 and B100 (20 percent biodiesel with 80 percent standard diesel, or pure biodiesel). B20 can be used with current technology while B100 may require some adjustments or new engines. The use of B20 would reduce GHG emissions by 10 percent, and B100 would reduce GHG emissions by 70 percent, reducing operational emissions by 2,300 to 3,000 metric tons CO_2e annually (varies by alternative).

Electrification—The benefits of shifting rail operations along the entire line to electricity have not been quantified at this time. Benefits would increase over the years as the New Hampshire grid shifts to increasingly higher fractions of renewable power sources (the New Hampshire grid currently includes relatively large fractions of nuclear and hydro power, which result in very little GHG emissions).

Sustainable Station Design and Construction—Although station energy use was not included in this analysis, new stations would be designed in accordance with the new requirements from the State.

Construction:

Use of Local, Renewable, Recycled Materials—75 percent of the construction emissions were estimated to come from the extraction, production, transport, and disposal of construction materials. Although precise details are not known at this time, the reduction in these emissions can be substantial if local, renewable, and recycled materials are used. The largest contributors are cement and steel. If emissions associated with material can be cut in half (existing strategies demonstrate that this is possible), the emissions payback period could be reduced by nearly 40 percent.

Biodiesel for Construction Engines—Biodiesel blends would be used in construction engines to the extent practicable.

Replanting Trees— Although not quantified in this analysis, any trees that need to be removed for construction would be replaced with a larger number of trees, replacing the trees in kind or more on a tree-mass basis.

SECTION 6 FUTURE ANALYSIS

The next level analysis will include the potential air quality implications of local traffic to and from stations, and of locomotives and other sources operating in rail yards and other locations other than the line-haul analyzed for Service-level. Potential construction impacts will also be analyzed. If the project is not included in the State Implementation Plan, an applicability analysis

will be performed to determine if a general conformity analysis is required. In addition, should in line-haul operations change substantially, micro-scale line-haul and meso-scale emissions likely would be investigated. The detailed GHG reduction measures may be reviewed and evaluated for applicability and practicability, and incorporated into the program as appropriate. In addition, beneficial measures will be quantified, if practicable. If substantial changes in design occur, the overall GHG emissions analysis will be reevaluated as well, and further refined if possible.

SECTION 1 NOISE AND VIBRATION

The noise and vibration limits chosen for construction and operation of the recommended project alternatives satisfy the federal guidelines of the Federal Transit Administration (FTA)[1] for train and rail facility operations.

1.1 METHODS FOR EVALUATION OF IMPACTS

The analysis of noise and vibration impacts used design information for the proposed alignment of the recommended project alternatives and regional rail traffic data. The FTA Guidance Manual provides guidelines for establishing the extent of the study area to be used for the noise and vibration impact analyses. It also provides guidance for identifying noise-sensitive locations where increased annoyance can occur from train pass-bys. The methodology followed by the noise and vibration analysts is described below.

1.2 NOISE- AND VIBRATION-SENSITIVE RECEPTORS

The noise-sensitive receptors for the analysis of all alternatives considered within the Environmental Assessment (EA) include relevant receptors that are defined by FTA criteria. The number of receptors potentially impacted have been determined using FTA's general assessment guidelines, including comparing existing with future noise levels and rating impacts. The vibration impact assessment uses the FTA general assessment procedure of determining if absolute vibration limits will exceed specified thresholds at vibration-sensitive receptors.

1.3 OPERATIONS NOISE

The descriptors and criteria for assessing noise impacts vary according to land use categories adjacent to the track. For land uses where people live and sleep (e.g., residential neighborhoods, hospitals, and hotels), L_{dn} is the assessment parameter. L_{dn} is the day-night average level, which is the energy-averaged sound level for a continuous 24-hour period with 10 decibels (dBA) added to all levels occurring between 10:00 pm and 7:00 am (to account for the added sensitivity to sounds during normal sleeping hours). For other land use types where there are noise-sensitive uses (e.g., outdoor concert areas, schools, and libraries), the equivalent (energy-averaged) noise level for an hour of noise sensitivity ($L_{eq(h)}$) that coincides with train activity is the assessment parameter. Table 1 summarizes the three land use categories.

The noise impact criteria used by the FTA are ambient-based; the increase in future noise (future noise levels with the recommended project alternatives added to existing noise levels) is assessed rather than the noise caused by each passing train. The criteria specify a consideration of future project noise with existing levels because this analysis with an existing condition considers annoyance due to the change in the noise environment caused by the recommended project alternatives. Figure 1 shows the FTA noise impact criteria for human annoyance. Depending on the magnitude of the cumulative noise increases, FTA categorizes impacts as (1) no impact; (2) moderate impact; or (3) severe impact. Severe impact is

[1] FTA. *Transit Noise and Vibration Impact Assessment*. USDOT Report Number FTA-VA-90-1003-06, May 2006

where a significant percentage of people would be highly annoyed by the project's noise. Moderate impact is where the change in cumulative noise levels would be noticeable to most people, but may not be sufficient to generate strong, adverse reactions.

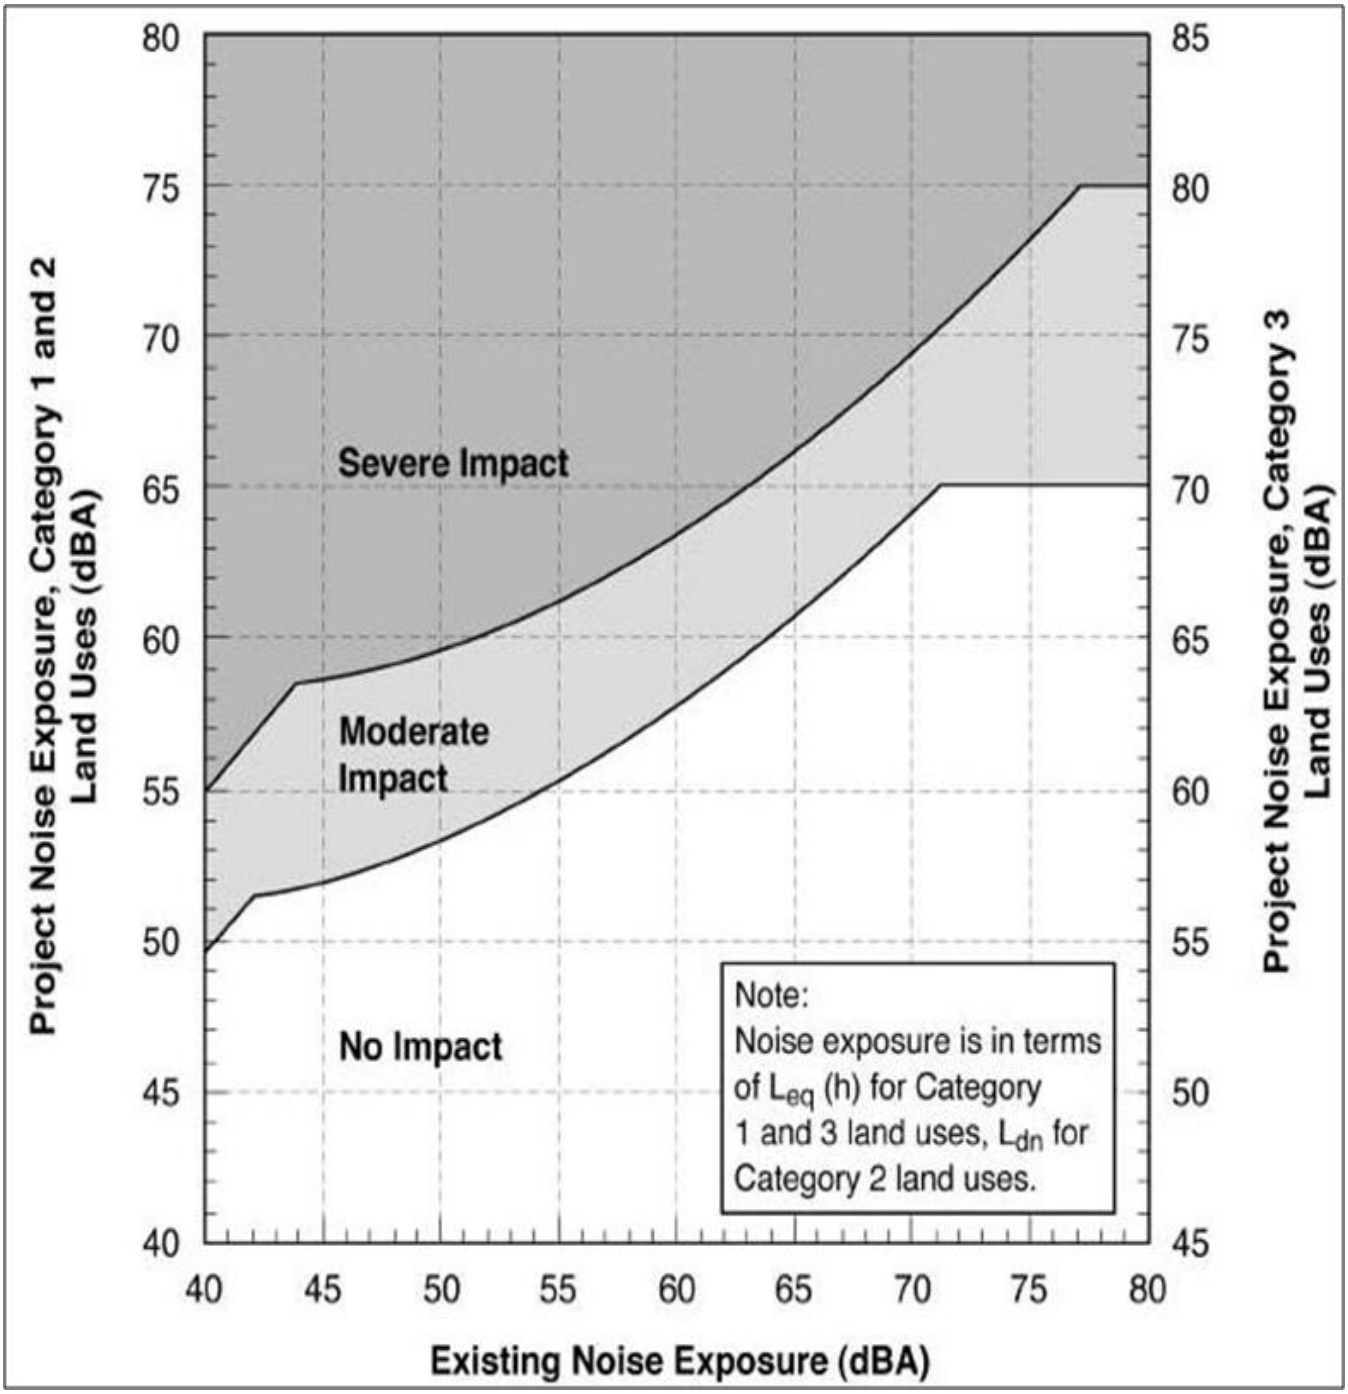
Table 1
FTA Noise-Sensitive Land Uses

Land Use Category	Noise Metric, dBA	Land Use Category
1	Outdoor $L_{eq(h)}$[(a)]	Tracts of land where quiet is an essential element in their intended purpose. This category includes lands set aside for serenity and quiet, such as outdoor amphitheaters, concert pavilions, and National Historic Landmarks with significant outdoor use.
2	Outdoor L_{dn}	Residences and buildings where people normally sleep. This category includes homes and hospitals, where nighttime sensitivity to noise is of utmost importance.
3	Outdoor $L_{eq(h)}$[(a)]	Institutional land uses with primarily daytime and evening use. This category includes schools, libraries, and churches, where it is important to avoid interference with such activities as speech, meditation, and concentration. Buildings with interior spaces where quiet is important, such as medical offices, conference rooms, recording studios, and concert halls fall into this category, as well as places for meditation or study associated with cemeteries, monuments, and museums. Certain historical sites, parks, and recreational facilities are also included.

Source: FTA 2006

(a)L_{eq} for the noisiest hour of transit-related activity during hours of noise sensitivity.

Figure 1
FTA Noise Impact Criteria



Source: FTA 2006

In addition to monitored existing background noise levels, the following assumptions and methodologies were used to establish existing noise levels along the alignment for all alternatives:

- Freight Train Noise – Calculations were based on the FTA Guidance Manual for train operations including warning horns, and the freight operation condition assumptions based on 2012 operations:

    - Operations – 3 through-freight trains per day (2 trains during daytime hours [7:00 am to 10:00 pm] and 1 train during nighttime hours [10:00 pm to 7:00 am]).

    - Speeds – 40 mph.

    - Length – 2 locomotives and 130 freight cars per train (1 train each during daytime and nighttime hours) and 1 locomotive and 30 freight cars per train (1 train during daytime hours); length of each locomotive of 89 feet; length of each freight car of 79 feet; total train set length of approximately 10,448 feet for 2 locomotives and 130 freight cars and 2,460 feet for 1 locomotive and 30 freight cars.

    - Horns – ¼-mile from each crossing affected by warning horns.

- Freight Train Crossing Signal Noise – The crossing signal noise would be more than 10 dBA less than the warning horn noise at the same receiver. According to the FTA guidelines, horns generate sound exposure levels of 110 dBA at 50 feet while a 2-minute crossing signal generates a sound exposure level of 94 dBA at 50 feet. Therefore, the crossing signal noise was considered negligible and it was not included in the existing noise calculation.

In addition, the following assumptions were used for the operational noise assessment for the inclusion of passenger train service, based on the design characteristics of the recommended project alternatives:

- Passenger Train Noise – Calculations were based on the FTA Guidance Manual for train operations including warning horns, and the following assumptions:

    Nashua Minimum Rail Service

    - Operations – 7 roundtrips per day between Lowell and South Nashua.

    - Speeds – 60 mph maximum.

    - Length – 1 locomotive per train; length of each locomotive of 89 feet; 9 passenger cars per train; length of each passenger car of 85 feet; total train set length of approximately 854 feet.

    - Horns – ¼-mile from each grade-crossing affected by warning horns, with 10 grade-crossings along the corridor.

    These assumptions result in predicted levels of 59 dBA L_{dn} at 50 feet between Lowell and Nashua for the passenger trains without horns.

- Crossing Signal Noise – For the reasons referenced above, the crossing signal noise would be negligible when compared to warning horn noise. Therefore, it was excluded from the noise calculations.

- Crossover Noise – The noise level would be greater with a train passing by at full speed compared with that for a train slowing down and traversing crossovers. Crossovers are switches that allow a train to move from one track to an adjacent track. There is noise generated by the train's steel wheels passing through these comparatively rough sections of track. Also, crossovers will be used infrequently by the passenger trains. Therefore, the worst-case scenario was taken into account and crossover noise was excluded from the noise calculations.

  Further, it was assumed that the rail track will be a combination of ballast and slab track with continuous welded rail, consistent with the assumptions in the FTA Guidance Manual and that there will be no change to the location of any of the existing at-grade-crossings and, therefore, no change to locations where the freight and passenger trains will sound their horns.

  Manchester Regional Commuter Rail Service

  - Operations – 17 roundtrips per day between Lowell and Nashua, 8 roundtrips per day between Nashua and Manchester.

  - Speeds – 70 mph maximum.

  - Length – 1 locomotive per train; length of each locomotive of 89 feet; 9 passenger cars per train; length of each passenger car of 85 feet; total train set length of approximately 854 feet.

  - Horns – ¼-mile from each grade-crossing affected by warning horns, with 26 grade-crossings along the corridor.

  These assumptions result in predicted levels of 65 dBA L_{dn} at 50 feet between Lowell and Nashua and 64 dBA L_{dn} at 50 feet between Nashua and Manchester for the passenger trains without horns.

  Intercity 8 Rail Service

  - Operations – 4 roundtrips per day between Lowell and Concord.

  - Speeds – 70 mph maximum.

  - Length – 1 locomotive per train; length of each locomotive of 89 feet; 9 passenger cars per train; length of each passenger car of 85 feet; total train set length of approximately 854 feet.

  - Horns – ¼-mile from each grade-crossing affected by warning horns, with 48 grade-crossings along the corridor.

These assumptions result in predicted levels of 57 dBA L_{dn} at 50 feet between Lowell and Manchester and 59 dBA L_{dn} at 50 feet from Manchester to Concord for the passenger trains without horns. Although there is one set of 4 roundtrips over the entire corridor for this alternative, the L_{dn} is higher between Manchester and Concord because there are nighttime (10:00 pm to 7:00 am) operations that transition to daytime (7:00 am to 10:00 pm) operations between Lowell and Manchester since the operations begin at 6:30 am each day in Concord.

1.4 OPERATIONS VIBRATION

Ground-borne vibration impacts from new rail operations inside vibration-sensitive buildings are defined by the vibration velocity level, expressed in terms of VdB, and the number of vibration events per day of the same kind of source. Table 2 summarizes vibration sensitivity in terms of the three land use categories and the criteria for acceptable ground-borne vibrations and acceptable ground-borne noise. Ground-borne noise is a low-frequency rumbling sound inside buildings, caused by vibrations of floors, walls, and ceilings. Ground-borne noise is generally not a problem for buildings near railroad tracks at- or above-grade, because the airborne noise from trains typically overshadows the effects of ground-borne noise. Ground-borne noise becomes an issue in cases where airborne noise cannot be heard, such as for buildings near tunnels.

The FTA provides guidelines to assess the human response to different levels of ground-borne vibration, as shown in Table 2. These levels represent the maximum vibration level of an individual train pass-by. A vibration event occurs each time a train passes the building or property and causes discernible vibration. “Frequent Events” are more than 70 vibration events per day, and “Infrequent Events” are fewer than 30 vibration events per day.

Table 2 includes separate FTA criteria for ground-borne noise (the "rumble" that radiates from the motion of room surfaces in buildings from ground-borne vibration). Although the criteria are expressed in dBA, which emphasizes the more audible middle and high frequencies, the criteria are significantly lower than airborne noise criteria to account for the annoying low-frequency character of ground-borne noise.

Table 2
FTA Ground-Borne Vibration and Ground-Borne Noise Operations Impact Criteria

Land Use Category	Ground-Borne Vibration Impact Criteria (VdB relative to 1 µin/sec[e])			Ground-Borne Noise Impact Criteria (dB re 20 µPa[f])		
	Frequent Events[a]	Occasional Events	Infrequent Events[b]	Frequent Events[a]	Occasional Events	Infrequent Events[b]
Category 1: Buildings where vibration would interfere with interior operations	65 VdB[c]	65 VdB[c]	65 VdB[c]	NA[d]	NA[d]	NA[d]
Category 2: Residences and buildings where people normally sleep	72 VdB	75 VdB	80 VdB	35 dBA	38 dBA	43 dBA
Category 3: Institutional land uses with primarily daytime use	75 VdB	78 VdB	83 VdB	40 dBA	43 dBA	48 dBA

Source: FTA 2006
(a) Frequent Events is defined as more than 70 vibration events per day.
(b) Infrequent Events is defined as fewer than 30 vibration events per day.
(c) This criterion limit is based on levels that are acceptable for most moderately sensitive equipment, such as optical microscopes. Vibration-sensitive manufacturing or research will require detailed evaluation to define the acceptable vibration levels. Ensuring lower vibration levels in a building often requires special design of the heating, ventilating and air conditioning systems, and stiffened floors.
(d) Vibration-sensitive equipment is not sensitive to ground-borne noise.
NA = Not Applicable
(e) micro inches per second, which is the FTA standard vibration velocity unit for vibration assessment
(f) standard reference for decibels in sound pressure level (the threshold pressure of human hearing) - 20 micro Pascals. Micro is 10 to the (-6) power

Because airborne noise often masks ground-borne noise for above-ground (i.e., at-grade or viaduct) trains, ground-borne noise criteria apply primarily to operations in a tunnel, where airborne noise is not a factor. The recommended project alternatives within the rail corridor from Lowell to Concord are planned to be at-grade only. As a result, ground-borne noise criteria are not expected to be issues for the recommended project alternatives. Further, for the recommended project alternatives, the impact criteria are based on "Infrequent Events" since they would not exceed 70 train events per day.

Rail operation noise and vibration levels were projected using current New Hampshire Department of Transportation (NHDOT) operation and plans for growth and the prediction models provided in the FTA Guidance Manual. Potential noise and vibration impacts were also evaluated in accordance with the FTA Guidance Manual. The assumptions for train operations are listed above (Section 1.3).

Analysts tabulated projected noise and existing ambient noise exposures at the identified receptors or clusters of receptors. The analysts determined the levels of impact (no impact, moderate impact, or severe impact) by comparing the existing and projected noise exposure based on the impact criteria shown in Figure 1.

1.5 STATION NOISE

A total of four new stations along the Project alignment are planned in the cities of Concord, Manchester, Bedford (Manchester-Boston Regional Airport), and Nashua. For each city, the recommended project alternatives were analyzed. Noise from each station would include train idling, warning horns, and auxiliary equipment. In addition, the speed of each train would be reduced around each station when compared with that of a train pass-by.

When a train slows down near a station, train pass-by noise levels will be reduced. However, the use of warning horns needs to be taken into account when trains approach (within ¼-mile of) each grade-crossing or station regardless of the train speed. Other station noise sources are considered negligible in the locations of the recommended project alternatives for Concord, Manchester, and Nashua, each of which being situated in highly-developed, urban areas with elevated ambient sound levels already existing, as well as in Bedford, New Hampshire, since that station is near the Manchester Boston Regional Airport. Other noise sources are less than horn noise at all locations by more than 10 dBA, in accordance with reference source noise levels in the FTA manual.

1.6 TRAFFIC NOISE

The criteria for highway noise impacts (relevant to the extent the recommended project alternatives cause changes in traffic patterns) are from the Federal Highway Administration (FHWA) Procedures for Abatement of Highway Traffic Noise and Construction Noise, as provided in 23 CFR Part 772. A Type 1 project is defined in 23 CFR Part 772 as a proposed federal or federal-aid highway project for the construction of a highway at a new location or the physical alteration of an existing highway that significantly changes either the horizontal or vertical alignment or increases the number of through-traffic lanes. FHWA requires identifying highway traffic noise impacts and examining potential abatement measures for all Type 1 projects receiving federal funds.

The recommended project alternatives will involve traffic increases to local roads, mainly around new stations, without any major changes to the existing roadway designs anticipated, so this would not be classified as a Type 1 project. Therefore, the traffic noise criteria for the recommended project alternatives would be the same as the FTA criteria presented in Figure 1.

1.7 CONSTRUCTION NOISE

Table 3 shows the FTA general assessment criteria for construction noise. The general assessment criteria for construction noise prescribe different levels for daytime and nighttime construction. Daytime is defined as 7:00 am to 10:00 pm and nighttime is defined as 10:00 pm to 7:00 am. For the purpose of this analysis, construction noise impacts and distances to the 90 dBA and 80 dBA 1-hour L_{eq} noise contours were calculated for construction activities, including train corridors and stations. The construction noise limits are normally assessed at the noise-sensitive receiver property line.

Table 3
General Assessment Criteria for Construction Noise

Land Use	One-Hour L_{eq} (dBA)	
	Daytime	Nighttime
Residential	90	80
Commercial	100	100
Industrial	100	100

Source: FTA 2006

The construction noise impact assessment used the general assessment methodology described in the FTA Guidance Manual. For this analysis, construction equipment for the rail corridor and stations are based on general assumptions for railroad construction. The construction noise methodology includes the following:

- Noise emissions from equipment expected to be used by contractors for corridor and station construction.
- Typical railroad construction equipment expected to be used by contractors.
- Two of the noisiest pieces of construction equipment per construction phase for corridor and station construction.
- Relationship of the construction operations to nearby noise-sensitive receptors.

Table 3 lists FTA criteria for the maximum acceptable 1-hour noise levels (L_{eq}) for daytime and nighttime.

1.8 CONSTRUCTION VIBRATION

The FTA Guidance Manual provides the basis for the construction vibration assessment.

FTA provides construction vibration criteria designed primarily to prevent building damage, and to assess whether vibration might interfere with vibration-sensitive building activities or temporarily annoy building occupants during the construction period. The FTA criteria include two ways to express vibration levels – (1) root-mean-square (RMS) VdB (L_v) for annoyance and activity interference; and (2) peak particle velocity (PPV), which is the maximum instantaneous peak of a vibration signal used for assessments of damage potential.

Table 4 shows the FTA building damage criteria for construction activity; the table lists PPV limits for four building categories. These limits are used to estimate potential problems that should be addressed during final design.

The FTA Guidance Manual provides the methodology for the assessment of construction vibration impact. Typical construction equipment included in the FTA Guidance Manual was used to conduct a quantitative construction vibration assessment where vibration-sensitive receptors were within the study

area. Criteria for annoyance (see Table 2) and damage (see Table 4) were applied to determine construction vibration impacts.

Table 4
Construction Vibration Damage Criteria

Building Category	PPV (in/sec)	Approximate L_v (VdB)
I. Reinforced concrete, steel, or timber (no plaster)	0.5	102
II. Engineered concrete and masonry (no plaster)	0.3	98
III. Non-engineered timber and masonry buildings	0.2	94
IV. Buildings extremely susceptible to vibration damage	0.12	90

Source: FTA 2006

SECTION 2 AFFECTED ENVIRONMENT

The affected environment follows the recommended project alternatives from Lowell, MA to Concord, NH within the existing freight rail corridor, as well as the recommended project alternatives for the stations in Nashua, Bedford, Manchester, and Concord. This region includes areas and communities within Middlesex County in Massachusetts and Hillsborough and Merrimack Counties in New Hampshire. These areas are mixed in terms of rural, residential, commercial, and industrial with isolated residential clusters considered to be suburban in nature, except for the downtown urban areas of Lowell, Nashua, Manchester, and Concord.

The recommended project alternative for each proposed station location falls within the urban areas of the cities of Lowell, Nashua, Manchester, and Concord. There are no applicable plans or policies for the region as a whole pertaining to noise and vibration within the rail corridor.

2.1 EXISTING NOISE LEVELS

Background noise monitoring was performed at 10 representative residential locations closest to the proposed Capitol Corridor rail line between Lowell, MA and Concord, NH. Each of the monitoring locations was in a concentrated residential community adjacent to the existing tracks. Roughly 24 hours of continuous data were recorded at each monitoring location, although the monitoring sessions were cut short to 22 hours for half of the sites due to steady rainfall occurring at the end of the those sessions.

Monitoring was performed between November 20 and 22, 2013 at the ten representative locations. Figure 2 shows these locations on a map of the entire study area. Each of these locations provides background sound levels representative of the closest residential communities to the project alignment. These locations were on residential properties adjacent to the rail line, all with a line-of-site to the rail line. These locations are:

1. 44 Elgin Street, Nashua, NH
2. 76 Gillis Street, Nashua, NH
3. 101 Atherton Avenue, Nashua, NH
4. 21 Cassandra Lane, Nashua, NH
5. 23 Caldwell Lane, Merrimack, NH
6. 13 Monadnock Lane, Merrimack, NH
7. 45 Bourne Drive, Bedford, NH
8. Colonial Village Apartments, behind building 145 (at southern end of parking lot closest to the rail), West River Road, Manchester, NH
9. 11 Lafond Avenue, Hooksett, NH

10. Williamsburg II development off Wellman Avenue, behind Unit 897, Chelmsford, MA

The weather conditions during the entire monitoring period were favorable for the sound level measurements with no precipitation, light winds (less than 10 miles per hour), and temperatures in the mid-20s at night to the mid- to upper-30s during daylight hours, all in degrees Fahrenheit until the morning of November 22, when it rained. Five sound monitors were used for these sessions – three Larson Davis Model 820 Type 1 (re ANSI S1.4-1983) sound level meters (serial numbers 1651, 1652, and 1655), a Larson Davis Model 720 Type 2 sound level meter (serial number 0395), and a Larson Davis Model 712 Type 2 sound level meter (serial number 0418). All meters were field-calibrated before and after the sessions with a Larson Davis Model CAL200 calibrator (serial number 5789). All instruments had been factory-calibrated within 12 months of their use and copies of their calibration certificates are in the project files. All measurement procedures were in accordance with standard industry-accepted practices. Photographs of the noise monitoring equipment were taken at each monitoring location. These photographs, showing the sound level meters with respect to the project site and nearby residential properties, are included in the Appendix to this report. Monitoring datasheets and instrument calibration certificates are available in the project files.

Day-night average noise levels (L_{dn}) measured at each of these sites are listed in Table 5.

Table 5
Monitored L_{dn} at Noise Monitoring Locations

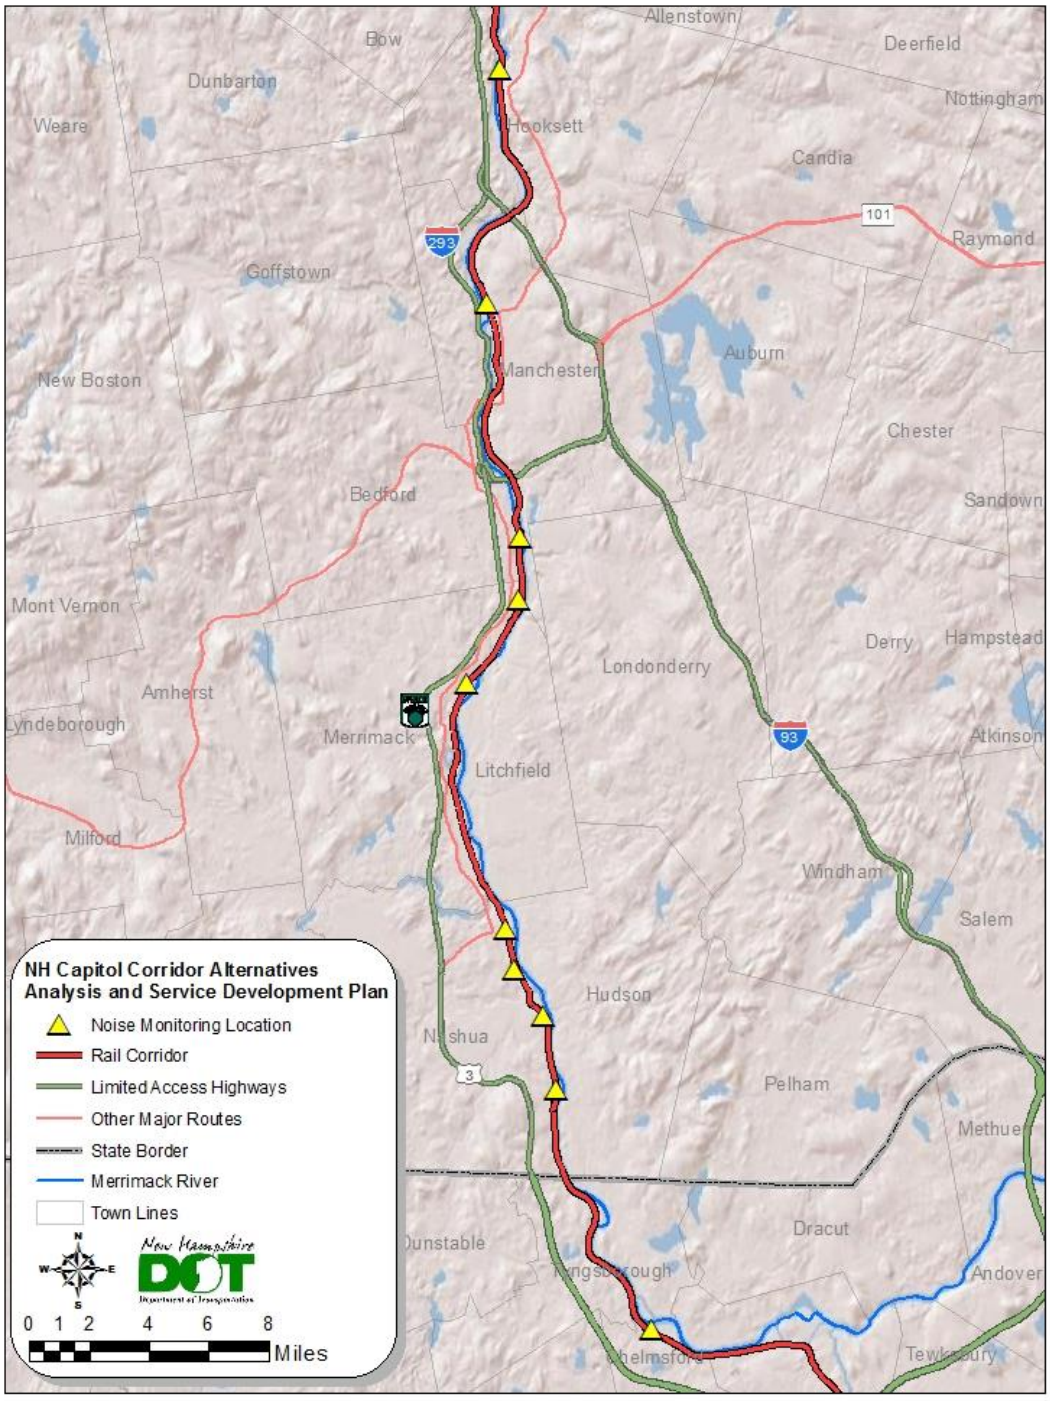
Noise Monitoring Location	Monitored L_{dn} (dBA)
1 – Elgin Street, Nashua	67*
2 – Gillis Street, Nashua	59
3 – Atherton Avenue, Nashua	50
4 – Cassandra Lane, Nashua	53
5 – Caldwell Lane, Merrimack	53
6 – Monadnock Lane, Merrimack	54
7 – Bourne Drive, Bedford	61**
8 – Colonial Apts., Manchester	59
9 – Lafond Avenue, Hooksett	56
10 – Williamsburg II, Chelmsford	59

*** - level elevated due to nighttime train operations**
**** - level elevated due to aircraft flyovers from Manchester airport**

In general, freight trains would generate 67 dBA L_{dn} at 50 feet from the rail tracks without horns. The noise level would drop off at a rate of 4.5 dBA per doubling of distance, per the FTA Guidance Manual. The warning horn noise level would be 74 dBA L_{dn} at 50 feet from the rail centerline within ¼-mile of each grade-crossing.

Warning horns would be the dominant noise sources when receptors are near grade-crossings. When receptors are not near grade-crossings, the dominant noise sources would be passing freight trains, passenger trains, or vehicular traffic.

Figure 2
Project Study Area with Noise Monitoring Locations



2.2 EXISTING VIBRATION LEVELS

Unlike the FTA noise impact assessment method, train-related vibration impact thresholds are not dependent upon existing ground-borne vibration levels, so the documentation of existing ground-borne vibration levels is not an issue as it is for noise levels.

As a reference, the existing freight trains generate 82 VdB at 50 feet when they operate at 40 mph. This reference is based on the methodology described in the FTA Guidance Manual.

SECTION 3 ENVIRONMENTAL CONSEQUENCES

3.1 OPERATIONS NOISE IMPACTS

No noise impacts would result from the No-Build Alternative in that this scenario maintains freight operations within the corridor with no projected and planned annual growth.

For the recommended project alternatives, analysts assessed noise impacts for noise-sensitive land uses based on a consideration of existing (2013) noise levels as measured at representative locations along the corridor, together with calculated future levels per the FTA Guidance Manual, which requires that impacts be considered based on the future project-generated levels resulting from the implementation of the recommended project alternatives. For this analysis, the recommended alternatives being considered are the Nashua Minimum Commuter Rail Service (with passenger service between Lowell and South Nashua), the Manchester Regional Commuter Rail Service (with passenger service between Lowell and Manchester), and the Intercity 8 Rail Service (with passenger service between Lowell and Concord).

Table 6 summarizes potential noise impacts related to the Nashua Minimum Commuter Rail Service Alternative by county, without mitigation, during the build-out year (2023).

Table 6
Summary of Unmitigated Noise Impact Results
Nashua Minimum Commuter Rail Service Alternative

County	Number of Severe Impact Parcels				Number of Moderate Impact Parcels			
	Residential Single Family	Residential Multi Family	Institutional	Recreational	Residential Single Family	Residential Multi Family	Institutional	Recreational

Merrimack (NH)	2	0		0	0	54	5		0	0

Source: URS Corporation, 2014

All of the predicted impacts under all three alternatives take into account the effects of horn soundings from the trains within ¼-mile of each grade-crossing approach. As explained in the Mitigation Section (Section 4), however, the impacts of such horns could be eliminated through the introduction of stationary

wayside horns at affected grade-crossings as a committed mitigation measure for severe and unmitigated impacts under all of the recommended project alternatives.

3.2 OPERATIONS VIBRATION IMPACTS

A vibration impact general assessment was conducted based on information in the FTA Guidance Manual. The factors considered in a general assessment include train speed, train-set, track system/support, track structure, propagation characteristics, coupling-to-building foundation, and type of building/receiver location in a building. Because any impacts would be relatively close to the tracks, a general soil type assumption was used and is appropriate for the level of detail of this analysis.

For the operation of the recommended project alternatives, none of the residential buildings in the study area would experience levels exceeding the FTA limits of 80 VdB for ground borne vibration and 43 dBA for ground borne noise. Likewise, no institutional buildings in the study area would experience levels exceeding the FTA limits of 83 VdB and 48 dBA (see Table 2). However, since there are planned to be more than 30 (but less than 70) operations in the segment of the Manchester Regional Commuter Rail Service Alternative between Lowell and South Nashua, the limit would be lowered from 80 VdB to 75 VdB in that area. This results in 77 single family residences and 42 multifamily residences being within the annoyance impact limit (see Table 2). These impacts could be eliminated by removing two round trips from the schedule for that alternative. In that case, as the above analysis indicates, none of the alternatives considered would be expected to result in operational vibration impacts.

3.3 STATION NOISE IMPACTS

A total of four proposed stations along the Project alignment are planned in the cities of Nashua, Bedford (at the MHT airport), Manchester, and Concord, New Hampshire as part of the recommended project alternatives**.** Each station location is in a highly developed urban area with predicted existing noise levels in the 65 to 70 dBA L_{dn} range at the closest residences. Noise from each station would include train idling, warning horns, and auxiliary equipment. In addition, the speed of each train would be reduced around the stations when compared to that for a train pass-by.

The dominant noise source near each station will be the warning horn. When a train slows down near a station, train pass-by noise will be reduced. However, the warning horn will be used when a train approaches each station regardless of the train speed. There are no noise- or vibration-sensitive parcels within 500 feet of any of the proposed station sites to be impacted by the station noise, including horn soundings. Therefore, station noise is considered negligible and not included in the impact calculation.

As the above analysis indicates, the recommended project alternatives would not be expected to result in noise or vibration impacts at or around the recommended station alternatives.

3.4 TRAFFIC NOISE IMPACTS

While traffic conditions will change for the roadways around the proposed stations, there are no new major roadways or roadway expansions anticipated for any of the recommended project alternatives. Because the proposed stations are located in busy downtown areas of Nashua, Bedford (at the MHT airport), Manchester, and Concord, the existing traffic volumes around the station sites are already high.

Based on the analysis completed for all alternatives considered, no traffic noise impacts are expected to be caused by traffic increases around the proposed stations.

3.5 CONSTRUCTION NOISE IMPACTS

Based on the construction noise impact criteria described in Table 3, the threshold noise levels would be 90 dBA L_{eq} for daytime hours (7:00 am to 10:00 pm) and 80 dBA L_{eq} for nighttime hours (10:00 pm to 7:00 am) for residential communities. Noise-sensitive receptors within 45 feet of construction activities would be potentially impacted during daytime hours and those within 145 feet would be potentially impacted during nighttime hours. Table 9 summarizes these impacts.

Table 9
Summary of Unmitigated Construction Noise Impact Results

County	Potential Daytime Impacts				Potential Nighttime Impacts			
	Residential Single Family	Residential Multi Family	Institutional	Recreational	Residential Single Family	Residential Multi Family	Institutional	Recreational
Middlesex (MA)	0	1	0	0	27	43	2	2
Hillsborough (NH)	3	0	0	0	205	29	0	1
Merrimack (NH)	0	0	0	0	11	2	1	1

Source: URS Corporation, 2014

Only 4 potential daytime impacts but up to 324 potential nighttime impacts have been identified as a result of the analysis conducted pursuant to the FTA guidelines. As explained in the Mitigation Section (Section 4), however, any such impact will be addressed through the introduction of committed mitigation measures under the recommended project alternative such that no significant impact would result.

3.6 CONSTRUCTION VIBRATION IMPACTS

During construction, some equipment may cause perceptible ground-borne vibrations, most notably pile driving equipment. If pile driving is used for the recommended project alternatives, it would only be for station construction. Construction equipment can produce vibration levels at 25 feet that range from 58 VdB for a small bulldozer to 112 VdB for a pile driver. Because there are receptors within the screening distances identified for construction vibration impact criteria in the FTA guidelines, the potential for vibration impacts during construction exists. These potential impacts would mostly depend on the locations of pile driving equipment (if used) associated with station construction. As explained in the Mitigation Section (Section 4), such an impact (if any) would be addressed through the introduction of committed mitigation measures under the recommended project alternative such that no significant impact would result.

SECTION 4 MITIGATION MEASURES

FTA guidance requires the consideration of mitigation measures for all severe impacts. The FTA 2006 impact assessment guide has guidelines that will be followed during construction. The following mitigation measures will be followed to address impacts that cannot be minimized or avoided by other means.

4.1 OPERATIONS NOISE

Warning horns on the trains have been calculated to generate impacts resulting from the all of the recommended project alternatives, as summarized in Tables 6, 7, and 8. If these impacts are not mitigated by separate action (such as efforts that may be undertaken independently by others), the project could mitigate these impacts with the installation of stationary wayside horns at the required grade-crossings where severe, unmitigated impacts exist. This measure would eliminate all severe noise impacts from occurring for all three of the recommended alternatives analyzed.

4.2 CONSTRUCTION NOISE

As shown on Table 9, four potential daytime impacts and 324 nighttime impacts have been identified as a result of the analysis conducted pursuant to the FTA guidelines. Construction noise will be monitored to verify compliance with the relevant noise limits. The contractor will have the flexibility to meet the FTA construction noise limits in the most efficient and cost-effective manner. In that regard, the contractor will have the flexibility of either prohibiting certain noise-generating activities during nighttime hours or by providing additional noise control measures to meet the noise limits.

To meet required noise limits, the following noise control mitigation measures will be implemented, as necessary, for nighttime and daytime:

- Install a temporary construction site sound barrier near a noise source.
- Avoid nighttime construction in residential neighborhoods.
- Locate stationary construction equipment as far as possible from noise-sensitive sites.
- Re-route construction-related truck traffic along roadways that will cause the least disturbance to residents.
- Monitor and maintain equipment to meet noise limits.
- Minimize the use of generators to power equipment.
- Limit the use of public address systems.
- Limit or avoid certain noisy activities during nighttime hours such as above-ground jackhammering and impact pile driving.

To mitigate noise related to pile driving (if needed), the use of an auger to install the piles instead of a pile driver would reduce noise levels substantially. Further, if pile driving is necessary for station construction, the time of day that the activity can occur will be limited.

Through the foregoing proposed measures, the limited and temporary construction noise impacts from the recommended project alternatives would be significantly reduced, and largely eliminated.

4.3 CONSTRUCTION VIBRATION

Because there are receptors within the screening distances identified for construction vibration impact criteria in the FTA guidelines, the potential for vibration impacts during construction exists. However, building damage from construction vibration is only anticipated from impact pile driving at very close distances to buildings. If piling occurs more than 25 to 50 feet from buildings, or if alternative methods such as push piling or auger piling can be used, impacts or damage from construction vibration is not expected to occur. Other sources of construction vibration do not generate high enough vibration levels for impacts or damage to occur. In any event, once a construction scenario has been established, preconstruction surveys are conducted at locations within 50 feet of piling to document the existing condition of buildings in case damage is reported during or after construction.

In light of the foregoing proposal to engage in alternative methods such as push piling or auger piling if and to the extent that piling must occur within 25 to 50 feet from existing buildings, impacts or damage from construction vibration are not expected to occur from the recommended project alternatives.

4.4 ADDITIONAL NOISE AND VIBRATION ANALYSIS FOLLOWING FINAL DESIGN

If final design or final specifications result in changes to the assumptions underlying the noise or vibration analyses, the Study team will reassess noise and/or vibration impacts and consider recommendations for mitigation, and provide supplemental environmental documentation, as required by FTA.

SECTION 5 SUMMARY OF POTENTIAL PROJECT IMPACTS

5.1 OPERATIONS NOISE IMPACTS

With the proposed recommended project alternatives, noise impacts are identified pursuant to the FTA guidelines. The predicted unmitigated noise impacts are due exclusively to the added warning horns from the recommended project alternatives.

With the institution of stationary wayside horns at the grade-crossings where severe, unmitigated noise impacts exist, the recommended project alternatives will have no adverse noise impact on the surrounding communities. In summary, with the institution of stationary wayside horns at the grade-crossings where severe, unmitigated impacts exist, the recommended project alternatives will have no adverse noise impact on the surrounding communities.

5.2 OPERATIONS VIBRATION IMPACTS

Due to the distance between the rail activities and the closest vibration-sensitive locations, no vibration-related impacts are anticipated with the recommended project alternatives, except for the segment between Lowell and South Nashua with the Manchester Regional Commuter Rail Service Alternative. These impacts could be mitigated by operational schedule changes.

5.3 STATION NOISE IMACTS

As the above analysis indicates, the recommended project alternatives would not be expected to result in noise or vibration impacts at or around the recommended project alternatives.

5.4 TRAFFIC NOISE IMPACTS

As outlined above, traffic noise produced by recommended project alternatives is not anticipated to cause significant impacts due to the already existing high ambient noise environment and lack of sensitive receptors in the impact range in the study area of the recommended project alternatives. There are, therefore, no significant traffic noise impacts anticipated under the recommended project alternatives.

5.5 CONSTRUCTION NOISE IMPACTS

Because the construction noise mitigation measures found above will be followed for the construction of the recommended project alternative, no noise impacts will result from the implementation of the recommended project alternative.

5.6 CONSTRUCTION VIBRATION IMPACTS

In light of the foregoing analysis showing that the construction of the recommended project alternatives is not expected to result in impacts exceeding FTA limits for residential buildings in the study area or for institutional buildings in the Project Area, there are no significant vibration impacts expected from construction of any of the recommended project alternatives**.**

Subject: N.H. Capitol Corridor Rail and Transit Alternatives Analysis – Contamination Inventory (Nobis File No. 87290.00)

Date: July 24, 2014

1.0 Introduction

Nobis Engineering, Inc. has prepared this Technical Memorandum to identify and describe environmental concerns with the potential to impact the proposed rail corridor.

1.1 Project Description

URS Corporation (URS), under contract with New Hampshire Department of Transportation (NHDOT), is preparing an Environmental Assessment (EA) for the Locally Preferred Alternative (LPA) in cooperation with the Federal Transit Administration (FTA), Federal Railroad Administration (FRA), and other relevant resource agencies. There will be one document produced by URS that:

- Updates previous work done for the FTA on service from Lowell to south Nashua;
- Assesses environmental impacts for transit alternatives from south Nashua to downtown Manchester; and
- Assesses environmental impacts for potential inter-city rail service from Boston to Concord for the FRA.

The EA will provide for scoping, public outreach, agency coordination, and preparation of required National Environmental Policy Act (NEPA) documentation for submission by the NHDOT. Data collection and impact analysis for the EA will be performed at a screening level or “high-level”, with overall air and noise effects from train operations considered. If a project emerges from this study, a site-specific impact analysis and field work would be performed in the future for a Project Level NEPA document (as described in the next section). The EA will be designed to meet the following objectives:

- Determine which aspects of the proposed action have potential for social, economic, or environmental impact;

Nobis Engineering, Inc.
18 Chenell Drive
Concord, NH 03301
T (603) 224-4182

- Identify alternatives and measures which might avoid, minimize, and/or mitigate adverse environmental impacts;
- Identify other environmental review and consultation requirements which should be performed concurrently with the EA; and
- Summarize public involvement and the results of agency coordination.

1.2 Task Objective

Nobis' task is to contribute to the environmental review and consultation requirements with respect to a review of documented environmental concerns proximal to the existing rail corridor and for ten properties proposed for construction of platforms or other support facilities. To support this objective, Nobis performed an initial environmental review of the LPA of the proposed transportation corridor from the Massachusetts border in Nashua, New Hampshire to the northern-most proposed facility in Concord, New Hampshire. The entire corridor received high-level screening of known contamination sites (Section 2.0 of this Technical Memorandum). Known and potentially contaminated sites with the potential to impact 11 proposed station stop, park and ride, and layover locations, as provided by URS, were reviewed in depth (Section 3.0 of this Technical Memorandum). It is noted that out of the 11 potential construction locations reviewed, 5 station locations and 1 layover location will ultimately be selected.

1.3 Contract Reference

This work was performed in accordance with a Master Subcontract for Services Between URS Corporation – New York and Nobis Engineering, Inc., effective January 23, 2012, and Work Authorizations NOB-2012-03, NOB-2012-04, NOB-2012-05, and NOB 2012-06 dated July 11, 2013.

2.0 High-Level Corridor Review

2.1 Description of Approach

The high-level review of the corridor provides an initial listing of the contaminated sites within 1,000 feet of the existing right-of-way. If intrusive activities are required in the right-of-way, *e.g.*, excavations that might encounter known groundwater and/or soil contamination, additional assessment of the contaminated site may be required to manage potential exposure to petroleum or hazardous substances. The NHDES OneStop Global Information System (GIS) website was used to identify contaminated sites within the 1,000-foot search distance. The website includes NHDES project sites with administrative tracking records, such as underground storage tanks (USTs) and hazardous waste generators, as well as contaminated sites with documented discharges or suspected discharges of petroleum or hazardous materials. These contaminated sites are shown on the Asbestos Disposal Sites (ADSs) and Remediation Sites GIS layers. Due to the limitations of the OneStop GIS website for this application, a conservative approach was

used where interpretation of the 1,000-foot search distance was required, *i.e.*, some NHDES project sites reviewed may be greater than 1,000 feet in map distance from the existing right-of-way.

In reviewing the corridor through the OneStop GIS website, three basic assumptions were applied: 1) the Merrimack River is considered to be a contaminant migration barrier; soil and groundwater contamination are assumed to not cross the river, 2) groundwater flow within 1,000 feet of the Merrimack River is generally toward the river, and 3) sites with a status of Closed or Inactive are assumed, in the absence of other mitigating factors or information, to be in compliance with state and federal requirements with respect to soil and groundwater. It is noted that, although regulators may not require additional action, Inactive ADSs may require special management if disturbed.

Given these assumptions, the corridor was reviewed relative to the following:

Is the NHDES project site shown on the Asbestos Disposal Site or Remediation Sites GIS layers?

If No – Not considered a contaminated site and no further review performed.

If Yes – Is the contaminated site within approximately 1,000 feet of the existing rail line, as depicted in GIS?

If No – No further review.

If Yes – Is the contaminated site on the same side of the Merrimack River as the rail right-of-way?

If No – No further review.

If Yes – listed in Table 1; is the site status other than Closed or Inactive?

If No – No further review.

If Yes – For contaminated sites with ongoing investigations or ongoing monitoring under a Groundwater Management Permit (GMP), is the site hydrologically upgradient of the rail right-of-way?

If No – No further review.

If Yes – refer to discussion in Section 2.3.

2.2 List of Contaminated Sites

The contaminated sites within the 1,000-foot search radius identified in accordance with the criteria above are listed in Table 1 in Attachment A.

2.3 Summary of Concerns and Recommendations

A contaminated site with an Activity and Use Restriction (AUR) may require additional assessment to understand the extent and limitations of the AUR if intrusive activities are required in close proximity to the AUR site. Reviewing NHDES and county records to determine the location of the AUR relative to the corridor may be all that is required. If an AUR includes or abuts the right-of-way, the AUR limitations should be reviewed to determine any restrictions on disturbances and material management requirements.

Contaminated sites that are hydrologically upgradient of the corridor and are monitored under a GMP may require additional assessment if intrusive activities have the potential to encounter contaminated groundwater. The assessment may consist of as little as a review of NHDES reports available online to determine the general depth to groundwater. If excavations are anticipated that have the potential to encounter contaminated groundwater, then additional assessment of existing records may be required to determine any precautions to limit worker exposure and manage contaminated water.

Inactive ADSs do not require ongoing monitoring and generally do not have administrative limitations. In light of the asbestos disposal history in the greater Nashua area and the industrial history of the properties adjoining the rail right-of-way, appropriate precautions are advisable for any activities requiring surficial disturbance. These precautions may include the need for ADS-certified workers and consultations with NHDES and City of Nashua personnel to determine the likely presence of asbestos waste. If encountered, waste containing asbestos will require management in accordance with State and Federal requirements.

Of the contaminated sites within 1,000 feet of the corridor, 81 were identified as having the potential to impact the corridor. Table 1 includes comments regarding these 81 contaminated sites.

3.0 Constructed Facility Location Review

3.1 Description of Approach

Nobis commissioned a database report from Environmental Date Resources, Inc. (EDR) for each of the properties proposed for construction of new facilities (Target Properties), based on the coordinates and figures provided by URS. The EDR report includes a summary of environmentally-related sites identified in State and Federal environmental databases (database sites). These sources include databases that track controlled facilities and/or activities, *e.g.*, hazardous waste generators and regulated USTs with no identified violations, as well as sites

with known contamination such as discharges of petroleum and/or hazardous waste, remediation activities, institutional controls as the result of discharges, and ongoing environmental monitoring due to discharges. The search radius of the database report for each Target Property conforms to ASTM 1527-13, Section 8.2.1, and is based on the approximate property or construction boundaries, as provided by URS.

For each Target Property, the detail map included in the EDR report was reviewed for indications of likely groundwater flow direction. Given the proximity of the rail corridor to the Merrimack River at all points, the groundwater flow was generally inferred to be toward the river, while recognizing that a component of groundwater flow may be in the southerly surficial flow direction of the river. This assumption of groundwater flow toward the Merrimack River was generally supported where reports or other data with interpreted flow direction were available; a southerly component is generally suggested in available reports as the distance from the river increases. Based on these assumptions, a generalized flow direction was inferred, and hydrologically upgradient and downgradient areas relative to the Target Property were defined. A portion of the detail map was then defined as the "area of potential impact" relative to the Target Property, based on applying professional experience with a variety of contaminated sites, the inferred groundwater flow direction, and the proximity of the database sites to the Target Property. This first-order review based on basic hydrogeologic principals and professional experience is considered appropriate for the purpose of this contaminated sites inventory. Recommendations for more rigorous review and assessment, based on preliminary findings and concerns, are included after the discussion of contaminated sites. For the MHT Airport / Wieczorek Drive property, defining an area of potential impact was unnecessary due to the small number of database sites identified. The EDR detail maps with the defined area of potential impact and inferred groundwater flow direction are included in Attachment A.

The database sites identified within the area of potential impact were then reviewed for the potential to be contaminated sites. For the purposes of this Technical Memo, Nobis defined contaminated sites as properties or facilities with known contamination, *e.g.*, leaking UST (LUST) sites, hazardous waste (haz waste) sites, or documentation suggesting a reasonable expectation of contamination, *i.e.*, spill sites, underground injection control (UIC) sites, disposal sites, and similar projects. Facilities tracked for administrative purpose, such as hazardous waste generators, were not considered contaminated in the absence of documentation of a discharge or unresolved violations. The exceptions to this are properties identified in the EDR Historical Cleaners database. This EDR database provides a listing of properties where dry cleaning business have been located that is based on non-environmental records, such as city directories. The halogenated volatile organic compounds associated with dry cleaning are dense, non-aqueous phase liquids (DNAPL) that have the potential for greater vertical distribution compared to petroleum products that are less dense than water. In addition to the potential for greater distribution, the potential for a Vapor Intrusion (VI) hazard to occupied buildings is generally greater for halogenated compounds. Given these factors, historical dry cleaning facilities in the defined area of potential impact were also considered for review, to the extent possible from existing records, without documentation of a discharge. It is noted that the lack of

a documented discharge at a historical dry cleaning facility may be the only method of assessment for potential impact to the Target Property, *i.e.*, if a dry cleaning facility is not on record as having a discharge, it is assumed that an impact to the Target Property is unlikely.

The contaminated sites within the defined area of potential impact for each Target Property are summarized in Table 2. Contaminated sites with New Hampshire Department of Environmental Services (NHDES) identifiers were reviewed for current status on the NHDES OneStop online database. Where possible and applicable, contaminated sites with United States Environmental Protection Agency (US EPA) identifiers were reviewed via the EPA Integrated Data for Enforcement Analysis (IDEA) website. Contaminated sites other than the Target Property listed as "Closed" were assumed, in the absence of other mitigating factors or information, to be in compliance with state and federal requirements with respect to soil, groundwater, and indoor air quality and, therefore, unlikely to impact the Target Property. Based on the above, contaminated sites other than the Target Property with a status of Closed, or Inactive for ADS, were not reviewed further. Likewise, contaminated sites hydrologically downgradient of the Target Property generally are assumed not to impact the Target Property but were reviewed for factors that might contradict that assumption. The available reports and other documentation for active sites were reviewed to establish the project work phase, *i.e.,* ongoing investigation, GMP, and/or AUR.

An AUR, as defined in Code of New Hampshire Administrative Rules Chapter Env-Or 600, Part 602, Section 602.01 Activity and Use Restrictions, generally applies to sites where a contaminant source cannot be removed due limitations to access, such as a source beneath a structure, or other logistics. The AUR acknowledges that a contaminant source remains that is not an overt contact hazard under controlled conditions and establishes a defined area with limitations and restrictions to usage and activities within the AUR area. The AUR generally defines the conditions that must be met to disturb the contaminant source and how the disturbance must be managed. The AUR is recorded in the chain-of-title for the property. If an impact to groundwater has been documented relative to the source, a GMP is likely to be associated.

A GMP is effectively an AUR with respect to groundwater only. A NHDES GMP defines a Groundwater Management Zone (GMZ) for a site with groundwater contamination exceeding the limits established in Section Env-Or 603.03 Ambient Groundwater Quality Standards (AGQS). Section Env-Or 602.13 defines a GMZ as "*the subsurface volume in which the groundwater contamination associated with a discharge is contained*". By definition, a GMP for a site confirms that the limits of groundwater contamination originating from the site, *i.e.*, the GMZ, have been identified. The GMP controls the use of groundwater within the GMZ as a drinking water source and establishes a monitoring program to track the progress of the selected remedial method, often a passive method such as natural attenuation, and confirm compliance with the GMZ with respect to the limits of contamination. The GMP may specify additional requirements such as indoor air monitoring where a VI hazard related to contaminant concentrations in groundwater has been identified. Notification of the existence of the GMP is recorded in the chain-of-title for all properties within the GMZ. It is noted that, as per NHDES policy, GMZs cannot overlap; a property cannot

be in more than one GMZ. A GMP is issued for a period of five years, with renewal required every five years, and remains in effect until AGQS are met.

The GMP sites within the area of potential impact of the Target Property were reviewed to confirm that the Target Property is not within the GMZ for a site and determine if further review for a VI hazard with respect the Target Property was necessary. Likewise, other contaminated sites not categorized as Closed or Inactive were reviewed for potential impacts to the Target Properties. Comments regarding the contaminated sites are included in Table 2 and the sites identified for additional review and discussion are noted. Target Properties identified as contaminated sites and other contaminated sites identified for additional review are discussed below.

3.2 Pheasant Lane Mall Property, Nashua

3.2.1 Contaminated Sites

Refer to Table 2, Page 1, for a list of contaminated sites in the area of potential impact for the Pheasant Lane Mall Property, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.2.2 In-Depth Review of Contaminated Sites

Pheasant Lane Mall (Target Property)

The Target Property is not depicted on historical Sanborn fire insurance maps. Aerial photographs depict undeveloped agricultural land until circa 1985. The Pheasant Lane Mall is identified as NHDES Site No. 198404009. Three spill response and two LUST projects are associated with the site; all five projects have a status of Closed. These projects are not directly associated with the portion of the property proposed for construction. The Closed status indicates that appropriate investigations and/or remedial actions have been completed and no further risk to human health and the environment is anticipated relative to the issue identified. These NHDES projects are unlikely to require additional management during construction in the defined area.

Non-Target Property Sites

No other contaminated sites were identified in the area of potential impact.

3.2.3 Summary of Potential Concerns

Based on the information available for review, no potential concerns are identified.

3.2.4 Recommended Further Action

As with any commercial transaction, the potential purchaser should complete a Phase I Environmental Site Assessment (ESA) in accordance with the practice set forth in ASTM E1527-

13 to fulfill the requirements of the EPA “all appropriate inquiries” (AAI) rule to be eligible for limitations on Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) liability, referred to as “landowner liability protections” (LLPs). The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as *Users*, as defined in ASTM E1527-13, 3.2.98, and the *Users* must fulfill the *User’s Responsibilities* specified in ASTM E1527-13, 6.

3.3 Hampshire Chemical Property, Nashua

3.3.1 Contaminated Sites

Refer to Table 2, Pages 1 and 2, for a list of contaminated sites in the area of potential impact for the Hampshire Chemical Target Property, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.3.2 In-Depth Review of Contaminated Sites

Hampshire Chemical Corporation (Target Property)

The Hampshire Chemical Corp. property at 2 East Spit Brook Drive, formerly identified as Hampshire Chemical Co. and W.R. Grace and Co., is identified in the OneStop database as a haz waste, UIC, and LUST site. Previous reports indicate that Hampshire Chemical Co. and its successors likely operated from circa 1959 through at least circa 1990. Prior to development as Hampshire Chemical Co., the property was apparently a field and possibly an airfield.

The UIC project was Closed in 1996.

Two LUST projects are established for the site with a status of Closed for both as of 1998 and 2006. According to NHDES records, ten USTs were formerly located on the property comprising one apparently unused tank, one containing diesel fuel, one containing No. 6 fuel oil, one containing No. 2 fuel oil, one containing waste oil and five listed as containing hazardous substances.

The haz waste project has a long history of investigation and assessment dating to the late 1980s that is too voluminous to summarize in depth in this Memo. The Target Property is currently the subject of GMP GWP-198704027-N-004 issued October 31, 2012. The GMP established a GMZ comprising the Target Property and the eastern-abutting Boston and Maine Corp. property; the eastern boundary of the GMZ is the Merrimack River (see Attachment B). An array of eight groundwater monitoring wells and three locations on the banks of the Merrimack River are monitored on a biennial basis with selected samples analyzed for VOCs, 1,4-dioxane, available cyanide, ammonia, formaldehyde, and sulfate. The submittal documenting the April 2013 monitoring reported concentrations of 1,4-dioxane, formaldehyde, and sulfate exceeding the applicable AGQS and elevated concentrations of ammonia.

Site-specific VI criteria were established for the site to address ammonia and cyanide in soil and hydrogen sulfide in groundwater. The criteria were applied to the development of an AUR that includes a ±10.9-acre portion of the ±41.3-acre property. The AUR is on the northeastern portion of the property and includes ±1,708.1 linear-feet of the ±2,859.4 linear-foot eastern boundary shared with the rail right-of-way to the east. The AUR outlines permitted activities and uses, restricted activities and uses, obligations and conditions, emergency procedures, and procedures needed to change the activities and uses and to terminate the AUR. It is noted that a vapor mitigation system is required for any occupied building on the property. The AUR is recorded at the Hillsborough Registry of Deeds in Book 8119 beginning on Page 380. The AUR, including a figure depicting the restricted area, is included in Attachment B.

Non-Target Property Sites

The contaminated sites in the area of potential impact are not considered to be significant concerns relative to the Target Property.

3.3.3 Summary of Potential Concerns

The documented contamination on the Target Property, including soil and groundwater exceeding applicable standards and a VI hazard, are the primary concerns. Redevelopment of the property will require vapor mitigation for occupied structures, and likely will involve management of contaminated soil and possibly contaminated groundwater.

3.3.4 Recommended Further Action

In considering the acquisition of the Hampshire Chemical property for further redevelopment as a commuter rail platform/station, the environmental history of the property and the implications of the AUR relative to design and construction should be fully understood. Based on the extensive documentation for this site, Nobis recommends that the potential purchaser commission an environmental report to summarize the work completed to date and identify potential data gaps that might require further investigation prior to redevelopment of the property. As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

3.4 Crown Street Property, Nashua

3.4.1 Contaminated Sites

Refer to Table 2, Pages 2 and 3, for a list of contaminated sites in the area of potential impact for the Crown Street Target Property, and the identifiers, category, and status of the contaminated

sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.4.2 In-Depth Review of Contaminated Sites

Crown Street Property (Target Property)

The 25 Crown Street property is identified in the EDR database report as Triangle Pacific Corp. The OneStop database indicates that it is a LUST, Unsolicited Site Assessment, and Brownfields site. A Phase I/II ESA completed in March 2013 by GZA GeoEnvironmental Corp. (GZA) on behalf of the City of Nashua indicates that Armstrong Cabinet Products operated on the property at the time of the assessment. GZA reported that the property was developed circa 1870 for manufacturing of doors, windows, and similar building supplies. Similar usage continued into the 1990s. As of the date of the GZA assessment, the property was used for offices, showroom, and warehousing. NHDES records indicate that the City of Nashua subsequently acquired the Target Property. NHDES reviewed the Phase I/II ESA and concurred with the conclusion that further investigation was not warranted relative to the information gathered for the assessment.

NHDES records indicate that five USTs were formerly located on the property consisting of one No. 6 heating oil tank, one diesel tank, and three hazardous materials tanks. The LUST project appears have originated in response to the closure report for the No. 6 heating oil UST. The LUST project was closed in early 2006. As part of the Phase I/II ESA, GZA completed six soil borings with five monitoring well installations in the former UST areas. Analytical results for soil samples did not exceed applicable NHDES standards for VOCs, total petroleum hydrocarbons, polynuclear aromatic hydrocarbons, or the eight Resource Conservation and Recovery Act (RCRA 8) metals arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver. Analytical results for groundwater samples did not exceed applicable NHDES standards for VOCs, semi-VOCs (SVOCs), and RCRA 8 metals.

GZA's Phase I/II ESA identified Recognized Environmental Conditions (RECs), as defined in the then-current E1527-05 Section 3.2.74. The RECs included a small stockpile of suspected transite (asbestos) roofing material, fill material derived from a demolished site building with the potential to contain asbestos, a basement room of unknown historical use that was posited to potentially have contained a storage tank or oil-containing machinery, and four 55-gallon drums of unknown provenance, the presence of which was apparently unknown to site personnel.

The EDR report cites a record of inspection No. 19891120NH007 1 in the FIFRA (Federal Insecticide, Fungicide, and Rodenticide Act) / TSCA (Toxic Substances Control Act) Tracking System (FTTS). The system tracks regulatory inspections in regions and states with cooperative agreements, enforcement actions, and settlements. The record apparently references a Section 6 PCB State-conducted PCB (polychlorinated biphenyl) inspection on November 20, 1989. The record notes a violation. No other records were identified in the NHDES database referencing inspection No. 19891120NH007 1. A corresponding reference (with no indication of a violation)

was identified in an EPA Facility Registry Service (FRS) Facility Detail Report available online. No additional details were available on the EPA website. Given the database and the lack of any additional records pertaining to this inspection, it is likely that it refers to an administrative violation such as labeling or record keeping. No other records pertaining to PCBs on the Target Property were identified. While the presence of PCBs in fluorescent light ballasts and older transformers is common, no information has been identified to suggest other PCB usage on the Target Property.

No further information regarding the Brownfields designation or determination of eligibility was identified in the records reviewed.

Non-Target Property Sites

The contaminated sites in the area of potential impact are not considered to be significant concerns relative to the Target Property.

3.4.3 Summary of Potential Concerns

The Target Property and vicinity has been developed for industrial use since prior to circa 1885, as documented by historical Sanborn fire insurance maps. Documented property usage nearby has included machine shops, a steam boiler works, and rail.

There is no documentation of current soil and groundwater contamination exceeding applicable standards, although it is noted that the halogenated compound trichloroethene (TCE) was detected in two groundwater samples at concentrations of 3.3 parts per billion (ppb) and 2.9 ppb; the NHDES AGQS for TCE is 5 ppb. The TCE was detected in a groundwater sample from a monitoring well sidegradient to the historical dry cleaner at 18 Arlington Street. Additionally, although the existing analytical data for soil do not exceed applicable standards, it is likely that redevelopment activities may expose soil requiring assessment and management. Based on the industrial development history of the site and general vicinity, the presence of petroleum and halogenated VOCs, PAHs related to coal use in the past, PCBs, and elevated metals concentrations is possible. The greater Nashua area has a history of asbestos disposal activities and the presence of as-yet unidentified fill containing asbestos is possible. It is further noted that GZA's Phase II activities were limited to assessing the former UST areas.

3.4.4 Recommended Further Action

The RECs identified in the Phase I/II ESA should be addressed either through additional assessment or clean-up, if they have not already been resolved. Given the industrial history of the Target Property and vicinity, additional Phase II investigation focused on assessing the property for potential materials management and/or clean-up during redevelopment appears to be prudent. As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The

Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

3.5 MHT Airport / Wieczorek Drive Property, Bedford

3.5.1 Contaminated Sites

Refer to Table 2, Page 3, for a list of contaminated sites in the area of potential impact for the MHT / Wieczorek Drive Target Property, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.5.2 In-Depth Review of Contaminated Sites

The EDR database report did not identify the Target Property as a contaminated site. The Target Property is not depicted on historical Sanborn fire insurance maps. Historical aerial photographs appear to depict the Target Property as undeveloped from 1947 through 1998. No contaminated sites requiring further review were identified.

3.5.3 Summary of Potential Concerns

No concerns relative to the Target Property were identified.

3.5.4 Recommended Further Action

As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

3.6 Manchester Wastewater Treatment Facility Property, Manchester

3.6.1 Contaminated Sites

Refer to Table 2, Page 3, for a list of contaminated sites in the area of potential impact for the Manchester Wastewater Treatment Facility Property, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.6.2 In-Depth Review of Contaminated Sites

Manchester Wastewater Treatment Facility (Target Property)

The Target Property is not depicted on historical Sanborn fire insurance maps. Aerial photographs indicate that the property was undeveloped until circa 1965. The Manchester Wastewater Treatment Facility is identified as NHDES Site No. 198509000. Four NHDES Projects are associated with the site. Three pertain to petroleum releases and one is associated with a sodium hypochlorite release. The sodium hypochlorite release is also the subject of Federal identifier DOT I-2010040279 as the result of a release to the ground surface during a delivery transfer. All NHDES Projects have a status of Closed except LUST Project 976.

A GMP is in effect for LUST Project 976; the GMZ established under the permit comprises the entire property. The available documentation indicates that the impacted area is inferred to be hydrologically downgradient relative to the rail right-of-way. The former location of the UST where the release occurred is also downgradient.

Non-Target Property Sites

The Fairpoint Communications site, NHDES Site No. 198806101, is LUST Project No. 16640 with petroleum contamination in groundwater that is monitored under a GMP. This site abuts the Target Property to the west and is inferred, in the context of the hydrogeologic setting, to be upgradient. It is noted that monitoring and investigation reports available in the NHDES OneStop database indicate a southeasterly groundwater flow direction that is inconsistent with the inferred westerly flow that is based on the proximity to the Merrimack River. Historical analytical results for groundwater samples collected from a monitoring well situated between the impacted area and the Target Property have indicated minor intermittent concentrations of petroleum compounds exceeding applicable NHDES standards. The well is no longer included in the GMP monitoring program.

3.6.3 Summary of Potential Concerns

The documented contamination on the Target Property does not appear likely to impact the proposed construction area.

In general, a GMZ implies that the limits of contamination are understood and are tracked through the GMP monitoring program. With respect to eastern-abutting Fairpoint site, the flow direction presented in historical reports appears to be inconsistent with the hydrogeologic setting. The information available for review in the OneStop database is insufficient to resolve the apparent contradiction between the inferred groundwater flow and the interpretation based on field data. If the documented flow direction is accurate, the site is unlikely to impact the Target Property. A conservative conclusion based only on the hydrogeologic setting is that construction on the Target Property has the potential to encounter groundwater contaminated with petroleum compounds at concentrations exceeding applicable NHDES standards. It is noted that NHDES appears to be in

agreement with the data interpretation historically presented for the Fairpoint site, which would suggest that an impact to the Target Property is unlikely.

3.6.4 Recommended Further Action

As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

If additional records review during the Phase I ESA cannot confirm that groundwater contamination at the Fairpoint site is unlikely to be migrating onto the Target Property, the conservative approach would be to complete a Phase II ESA that would include installation of one or more monitoring wells near the Target Property / Fairpoint property boundary. Alternately, provisions for managing contaminated groundwater, if encountered during construction, could be included in construction plans.

3.7 Pine Grove Cemetery Property, Manchester

3.7.1 Contaminated Sites

Refer to Table 2, Page 3, for a list of contaminated sites in the area of potential impact for the Pine Grove Cemetery Property, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.7.2 In-Depth Review of Contaminated Sites

<u>Pine Grove Cemetery (Target Property)</u>

The proposed construction area is an undeveloped portion of a larger property. The Target Property is not depicted on historical Sanborn fire insurance maps. Aerial photographs from 1952 through 2012 confirm that the proposed construction area has not been developed. The Pine Grove Cemetery is identified as NHDES site No. 199504003. LUST Project No. 5699 and On-Premises Use Facility (OPUF) Project No. 20091 both have a status of Closed. Both are related to UST installations more than one-quarter mile from the proposed construction area. Neither of these projects is likely to impact the proposed construction area.

<u>Non-Target Property Sites</u>

One contaminated site in the area of potential impact has a status of Closed and is not considered to be a significant concern relative to the Target Property.

3.7.3 Summary of Potential Concerns

The historical contamination on the Target Property was not near the proposed construction area and no concerns are related to the previous releases.

3.7.4 Recommended Further Action

As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

3.8 Hancock Street Property, Manchester

3.8.1 Contaminated Sites

Refer to Table 2, Page 3, for a list of contaminated sites in the area of potential impact for the Hancock Street Property, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.8.2 In-Depth Review of Contaminated Sites

Hancock Street Property (Target Property)

The EDR database report did not identify the Target Property as a contaminated site. An historical Sanborn fire insurance map dated 1915 depicts the Manchester Rendering Co. on the northern portion of the Target Property adjacent to the western terminus of Hancock Street. Of note on the map is a portion of the building labeled "oil storage", presumably referencing animal byproducts, not petroleum. The notation "oleo factory" is shown in the same building area. Railroad tracks are depicted along the eastern property boundary and are depicted on all later maps. The W.H. McElwain Company "Central Plant" is depicted on the southern portion of the Target Property. Although structures are described, no buildings are depicted. It appears to be a manufacturing facility but the nature of the operations is not clear from the description on the map. The same description is included on the 1950 map with the name International Shoe Company "Central Plant". This 1950 labeling appears to be overwritten by an additional structure added to the Manchester Rendering Co., suggesting that maps are missing between 1915 and 1950. The 1954 map depicts the Manchester Rendering Co. and the notations related the "Central Plant" are not present. The maps from 1971, 1973, 1975, 1983, 1895, and 1989 depict M.R. Co., presumably referencing Manchester Rendering Co., and the buildings are either not depicted or are overwritten. Also depicted on maps from 1950 through 1989 is the Granite State Packing Co. adjoining the railroad tracks to the east. Historical aerial photographs appear to

depict the Target Property as undeveloped from 1947 and 1952, however, the resolution is poor. The building on the northern portion can be seen in the 1952 image. The 1965, 1977, 1985, and 1992 images appear to depict the Target Property as vacant with the Granite State Packing Co. building adjoining to the east. A building is present on the Target Property in the 1998 image and it appears to be connected to the packing plant to the east by a structure that bridges the railroad tracks. The 2006 and 2008 images similarly depict the connected buildings. The 2009 image depicts the building on the Target Property and adjoining (and connected) building to the east is gone. The 2011 and 2012 images appear to depict the building on the Target Property gone and a new structure to the east. The aerial images appear to be generally consistent with the historical maps. The Target Property is not identified in the EDR report as a contaminated site.

Non-Target Property Sites

Three contaminated sites in the area of potential impact has the status of Closed and are not considered to be a significant concern relative to the Target Property.

3.8.3 Summary of Potential Concerns

Although the Target Property and surrounding area have been developed for industrial use since prior to 1915, the available documentation does not suggest that significant concerns have been identified.

3.8.4 Recommended Further Action

As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

3.9 Riverwalk Way and South Commercial Street Property, Manchester

3.9.1 Contaminated Sites

Refer to Table 2, Page 4, for a list of contaminated sites in the area of potential impact for the Riverwalk Way and South Commercial Street, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.9.2 In-Depth Review of Contaminated Sites

Riverwalk Way and South Commercial Street (Target Property)

The EDR database report did not identify the Target Property as a contaminated site. Historical Sanborn fire insurance maps from 1885 and 1891 depict railroad tracks and an engine house at the proposed construction area. Maps from 1915 through 1950 depict tracks. Maps from 1954 through 1989 depict rail facilities to the east but do not depict the proposed construction area.

Non-Target Property Sites

The historical maps generally depict the area to the east of the Target Property as commercial and industrial development. The contaminated sites identified in the database do not appear likely to impact the Target Property.

3.9.3 Summary of Potential Concerns

The Target Property was developed for rail use prior to 1885 and the general area has been developed for rail and industrial use since at least that same time period. Experience with numerous sites in the greater Manchester area generally finds urban fill containing ash in the subsurface. Numerous properties in the areas of Manchester with long industrial/commercial development histories have also been impacted by halogenated VOCs. Additionally, ash is commonly identified on properties historically used for rail facilities. While there are no overt indications of activities in the vicinity that would impact the target property, the development history suggests a potential for the presence of petroleum or hazardous substances in the subsurface.

3.9.4 Recommended Further Action

Given the development history of the Target Property and vicinity, an investigation focused on assessing the property for potential materials management and/or clean-up during redevelopment is prudent. As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

3.10 Granite Street and Canal Street Property, Manchester

3.10.1 Contaminated Sites

Refer to Table 2, Pages 4 and 5, for a list of contaminated sites in the area of potential impact for the Granite and Canal Street Target Property, and the identifiers, category, and status of the

contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.10.2 In-Depth Review of Contaminated Sites

Granite and Canal Streets (Target Property)

The EDR database report did not identify the Target Property as a contaminated site. The property is depicted on historical Sanborn maps dated 1885 and 1891 as rail tracks and a freight depot. An 1897 map depicts tracks only. The 1915 through 1954 maps depict rail tracks and a rail station and associated facilities. The 1971 and 1983 maps depict rail tracks and parking; the 1985 and 1989 maps depict rail tracks and a commercial building on the southern portion and parking. The building is currently occupied by Hampshire First Bank with an address of 80 Canal Street.

Non-Target Property Sites

The historical maps generally depict the area surrounding the Target Property as commercial and industrial development to the west and commercial development to the east. The contaminated sites identified in the database do not appear likely to impact the Target Property.

3.10.3 Summary of Potential Concerns

The Target Property was developed for rail use prior to 1885 and the general area has been developed for commercial and industrial use since at least that same time period. Experience with numerous sites in the greater Manchester area generally finds urban fill containing ash in the subsurface. Numerous properties in the areas of Manchester with long industrial/commercial development histories have also been impacted by halogenated VOCs. Additionally, ash is commonly identified on properties historically used for rail facilities. While there are no overt indications of activities in the vicinity that would impact the target property, the development history suggests a potential for the presence of petroleum or hazardous substances in the subsurface.

3.10.4 Recommended Further Action

Given the development history of the Target Property and vicinity, an investigation focused on assessing the property for potential materials management and/or clean-up during redevelopment is prudent. As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as

defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

3.11 Spring Street and Canal Street Property, Manchester

3.11.1 Contaminated Sites

Refer to Table 2, Page 5, for a list of contaminated sites in the area of potential impact for the Spring Street and Canal Street Property, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.11.2 In-Depth Review of Contaminated Sites

Spring Street and Canal Street (Target Property)

The EDR database report did not identify the Target Property as a contaminated site. Historical Sanborn fire insurance maps from 1897 through 1975 depict an industrial canal. Maps from 1983 through 1989 depict rail tracks only. Historical aerial photographs are generally consistent with the conditions depicted on the Sanborn maps.

Non-Target Property Sites

The historical maps generally depict the area surrounding the Target Property as commercial and industrial development to the west and commercial development to the east. The contaminated sites identified in the database do not appear likely to impact the Target Property.

3.11.3 Summary of Potential Concerns

The Target Property was developed as an industrial canal prior to 1887 and the general area has been developed for commercial and industrial use since at least that same time period. Industrial canals have the potential to be used for inappropriate disposal of wastes. Experience with numerous sites in the greater Manchester area generally finds urban fill containing ash in the subsurface. Numerous properties in the areas of Manchester with long industrial/commercial development histories have also been impacted by halogenated VOCs. While there are no overt indications of activities in the vicinity that would impact the target property, the development history suggests a potential for the presence of petroleum or hazardous substances in the subsurface.

3.11.4 Recommended Further Action

Given the development history of the Target Property and vicinity, an investigation focused on assessing the property for potential materials management and/or clean-up during redevelopment is prudent. As with any commercial transaction, the potential purchaser should complete a Phase

I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

3.12 Stickney Avenue Property, Concord

3.12.1 Contaminated Sites

Refer to Table 2, Pages 6 and 7, for a list of contaminated sites in the area of potential impact for the Stickney Avenue Target Property, and the identifiers, category, and status of the contaminated sites. The assumptions discussed above and the comments in Table 2 address the necessity of further review.

3.12.2 In-Depth Review of Contaminated Sites

Stickney Avenue Property (Target Property)

The Target Property is identified as the former NHDOT facility located at 11 Stickney Avenue. The property has been a NHDOT garage, maintenance facility, and materials research facility. An historical Sanborn map dated 1928 depicts a New Hampshire State Highway Department facility constructed circa 1926. A garage, woodworking shop, auto repair shop, machine shop, and storage areas are identified on the map. The development prior to 1926 is unclear; the Sanborn maps prior to 1928 do not appear to depict the Target Property. Groundwater Technology, Inc. completed a Site Investigation (SI) Report dated January 18, 1996 that detailed current and previous activities on the property. The documented activities include warehousing, heavy and light vehicle maintenance, a sign painting shop, welding and machine shop, carpentry, materials research, and vehicle painting. A Supplemental SI completed by Nobis Engineering, Inc. in 2001 detailed storage of heating oils in 16 aboveground storage tanks (ASTs) that have existed on the property as well as motor oil and solvents contained in various sizes of drums. The SSI documented a 2,000-gallon oil-water separator and a hazardous waste storage area primarily used for waste solvents and paint shop waste including lead-based paints. A commercial truck and equipment painting operation appears to currently operate on the property.

NHDES files indicate two UIC projects that were closed as of 2007 and 2004.

A NHDES Initial Response Spill project was closed in 2000.

A NHDES OPUF project was closed in 2001.

NHDES records available for review online indicate that no USTs remain on the site. The available documentation indicates that 14 diesel and gasoline USTs have existed on the site in the past.

NHDES haz waste and LUST projects are monitored under GMP No. GWP-199004021-C-003 issued October 21, 2010. The GMP defines the GMZ as the property boundary and requires annual monitoring with samples collected from two monitoring wells analyzed for VOCs. The most recent monitoring data indicate the presence of petroleum and halogenated VOCs; only the gasoline additive methyl tertiary-butyl ether (MtBE) remains at concentrations exceeding AGQS. No VI hazard is identified.

Non-Target Property Sites

The contaminated sites in the area of potential impact are not considered to be significant concerns relative to the Target Property.

3.12.3 Summary of Potential Concerns

The Target Property has a history as a vehicle repair and machine shop facility since at least circa 1926. Sign and vehicle painting has been conducted on the property during the prior NHDOT usage and vehicle painting continues currently as a commercial operation. Based on the development history, the presence of petroleum and halogenated VOCs, PAHs related to coal use in the past, hazardous materials related to painting and solvent usage, and elevated metals concentrations in the subsurface is possible.

3.12.4 Recommended Further Action

Given the development history of the Target Property and vicinity, an investigation focused on assessing the property for potential materials management and/or clean-up during redevelopment appears to be prudent. Existing historical records should be reviewed to identify the locations of past activities that included petroleum and hazardous materials, and to determine if these areas have been assessed to date. As with any commercial transaction, the potential purchaser should complete a Phase I ESA in accordance with the practice set forth in ASTM E1527-13 to fulfill the requirements of the EPA AAI rule to be eligible for limitations on CERCLA liability, referred to as LLPs. The Phase I ESA must identify all parties relying on the assessment for eligibility for LLPs as Users, as defined in ASTM E1527-13, 3.2.98, and the Users must fulfill the User's Responsibilities specified in ASTM E1527-13, 6.

4.0 Summary and Conclusion

Of the contaminated sites identified within 1,000 feet of the corridor during the high-level review, 81 sites were identified as having the potential to impact the corridor. A contaminated site with an AUR may require additional assessment to understand the extent and limitations of the AUR if intrusive activities are required in close proximity to the AUR site. Contaminated sites that are hydrologically upgradient of the corridor and are monitored under a GMP may require additional assessment if intrusive activities have the potential to encounter contaminated groundwater. Inactive ADSs do not require ongoing monitoring and generally do not have administrative limitations. In light of the asbestos disposal history in the greater Nashua area and the industrial

history of the properties adjoining the rail right-of-way, appropriate precautions are advisable for any activities requiring surficial disturbance. The need for further review and assessment of contaminated sites with the potential to impact the corridor that were identified during the high-level review is contingent on the nature of repairs and/or upgrades to the existing right-of-way.

Areas of potential impact were established for e Target Properties and Federal and State environmental databases were reviewed for sites within the defined area with a history of discharges of petroleum and hazardous substances. Where identified, these contaminated sites were assessed for the potential to impact the Target Property.

The MHT Airport / Wieczorek Drive property has no identified history of industrial or commercial development. The proposed construction area of the Pine Grove Cemetery does not appear to have been developed although the cemetery has existed since at least 1952. The Hancock Street property, the Riverwalk Way and South Commercial Street property, the Granite and Canal Street property, and the Spring Street and Canal Street Property have not been investigated relative to a documented or potential discharge, although all are in areas with historical commercial and/or industrial development. Of the Target Properties where investigations have been conducted, the Pheasant Lane Mall Property, the Crown Street property, and the Pine Grove Cemetery property are not currently monitored under institutional controls. The Manchester Wastewater Treatment Facility is monitored under a GMP. The Hampshire Chemical property is the subject of an AUR that limits activity and development. The property is also the subject of a GMP that controls groundwater usage and requires ongoing monitoring within the GMZ. The Stickney Avenue property is the subject of a GMP that controls groundwater usage and requires ongoing monitoring within the GMZ.

Of the developed properties, the Hampshire Chemical property is the most impacted. Approximately one-quarter of the property is under an AUR due to the concentrations of ammonia and cyanide in soil and hydrogen sulfide in groundwater. It is noted that some restrictions of the AUR apply to the entire property, not just the defined AUR area. The concentrations of 1,4-dioxane, formaldehyde, and sulfate in groundwater exceed applicable NHDES standards. Although NHDES does not establish a groundwater standard for ammonia, the concentrations in groundwater are elevated to the degree that a risk-based site-specific standard was defined for the Hampshire Chemical site. Site-specific VI criteria were established for the property and the AUR includes vapor mitigation requirements for construction.

The identified groundwater contamination at the Stickney Avenue property is currently limited to MtBE. Other petroleum and halogenated VOCs have been present but the concentrations are currently below applicable standards.

The Manchester Wastewater Treatment Facility is monitored as the result of a petroleum release from a UST. The impacted area appears to be hydrologically downgradient of the proposed construction area, however; the abutting, apparently hydrologically upgradient, property is also

the subject of a GMP as the result of a petroleum release from a UST. There is ambiguity with respect to the groundwater flow direction inferred from the hydrologic setting and the direction interpreted from data collected at the abutting property.

Soil and groundwater assessment completed to date at the Crown Street property focused on former USTs. The analytical data available do not indicate concentrations of VOCs exceeding applicable standards. A Phase I/II ESA cited RECs identified on the property. It is noted that a REC is not necessarily a confirmation of a discharge or release but an indication of the potential for a discharge or release based on records, observations, or other information gathered during the Phase I process. The current status of the RECs is unknown. The property and vicinity have been developed for industrial/commercial use since prior to 1885.

No records of investigation or assessment of soil and groundwater at the Hancock Street, Riverwalk Way and South Commercial Street, Granite and Canal Street, and Spring and Canal Street properties have been identified. The properties and the properties nearby have been developed for industrial/commercial use since prior to 1885.

While the Pheasant Lane Mall property is heavily developed, the proposed construction area is generally south and east of the development. Likewise, the Pine Grove Cemetery property is developed, but the proposed construction area is not.

The MHT Airport / Wieczorek Drive property appears to have been undeveloped prior to the construction of Wieczorek Drive.

None of the non-Target Property contaminated sites appear to have overt potential to impact the Target Properties with the exception of the Fairpoint Communications site to the east of the Manchester Wastewater Treatment Facility. As discussed previously, the reported hydrologic gradient at this site is inconsistent with the setting. As a result, the potential for an impact to the Target Property seems to be unclear. It is noted that NHDES apparently accepts the interpretations presented in investigation and monitoring reports for the Fairpoint site and believes the extent of groundwater contamination to be defined.

As discussed in Section 3, Phase I ESAs should be completed for each property that will be acquired in order to be eligible for LLPs. If RECs are identified during the Phase I ESA process, the RECs should be addressed through clean-up or further investigation through a Phase II assessment. If a Phase I ESA does not identify data clarifying the groundwater flow direction at the Manchester Wastewater Treatment Facility property and the eastern abutting property, additional investigations, or contingencies for managing petroleum contaminated groundwater during construction, should be considered. Based on the development histories of the properties and surrounding areas, it is advisable that the Crown Street, Riverwalk Way and South Commercial Street, Granite and Canal Street, Spring and Canal Street, and Stickney Avenue properties be assessed for the presence of petroleum or hazardous substances that might require management or disposal, regardless of the findings of a Phase I ESA. Given the history and

settings of these properties, assessment of subsurface conditions for the presence of VOCs, PAHs, PCBs, and RCRA 8 metals in soils is advisable. Assessment for asbestos should be considered for the Crown Street property.

Based on the extensive investigations and other activities completed at the Hampshire Chemicals property, the nature and distribution of contamination appears to be documented. A summary of the investigations completed to date should be compiled and any data gaps identified, relative to planned redevelopment. The limitations and requirements of the AUR should be considered relative to redevelopment plans. If data gaps are identified, additional investigations may be warranted.

Prescott and Sons Oil	196 North Main Street-rear (Storrs Street Extention), Concord	199407068, Project 12362	LAST	GMP	upgradient, petroleum free product	yes - refer Section 2.3
Concord Center Trust	10 Ferry Street, Concord	199307012, Project 14150	ADS	Inactive		possible - refer to Section 2.3
Concord Center Trust	10 Ferry Street, Concord	199307012, Project 4388	Haz Waste	Closed		no
Concord Center Trust	10 Ferry Street, Concord	199307012, Project 5040	LUST	Closed		no
Hess Station 29500	175 North Main Street, Concord	199306008, Project 4319	LUST	GMP	upgradient	yes - refer Section 2.3
Hess Station 29500	175 North Main Street, Concord	199306008, Project 12767	Oil Spills/Releases	Closed		no
Lockwood Young Corp.	South Commercial Street, Concord	198805015, Project 2106	UIC	Closed		no
Lockwood Young Corp.	South Commercial Street, Concord	198805015, Project 549	LUST	Closed		no

Recommendations are relative to the criteria in Section 2; other factors may apply relative to Section 3.
Contaminated Sites: site where contamination is known to exist or has existed in the past
VOC: Volatile Organic Compounds, often petroleum or solvent (halogenated) related
AUR: Activity and Use Restriction
GMP: Groundwater Management Permit
RAP: Remedial Action Plan
Haz Waste: Hazardous Waste Discharge
LUST: Leaking Underground Storage Tank (petroleum)
OPUF: On-Premises-Use Facility
ADS: Asbestos Disposal Site
MOST: Motor Oil Storage Tank
ETHER: Ether contaminated site.
UIC: Underground Injection Control (commonly floor drains not related to septic or sewer systems)
LAST: Leaking Aboveground Storage Tank

TABLE 2

Summary of Contaminated Sites - Potential Construction Target Properties

N.H. Capitol Corridor Rail and Transit Alternatives

Target Property	Contaminated Sites								
	Site Name	EDR Detail Map Identifier	Site Address	Federal Identifiers	State Identifiers	Alternate Names	Site Type	Status	Comments
Pheasant Lane Mall	*Pheasant Lane Mall	A	310 Daniel Webster Highway		198404009, Project 31020	PSNH	Initial Response Spill Site	Closed	
	*Pheasant Lane Mall	A	310 Daniel Webster Highway		198404009, Project 30532	PSNH	Initial Response Spill Site	Closed

	Import Connections	G34	512 Willow Street		200704033, Project 17953		UIC	Closed	
	Import Connections	G34	512 Willow Street		200704033, Project 18126		Haz Waste	Closed	upgradient, AUR, no impact to Target Property likely
	Import Connections	G34	512 Willow Street		200704033, Project 16726		Leaking Motor Oil Storage Tank	Closed	
	Advanced Recycling, TS Schnitzer	K56	399 Willow Street		198606070, Project 15861	Amoskeag Bank, Prolerized New England Co.	UIC	Closed	
	Advanced Recycling, TS Schnitzer	K56	399 Willow Street		198606070, Project 15619	Amoskeag Bank, Prolerized New England Co.	Ether Contaminated Site	non-GMP monitoring	up to sidegradient, arsenic in one well, no impact to Target Property likely
	other sites are unlikely to impact the Target Property due to distance, nature of the release, and/or hydrologic setting								
Granite and Canal Streets	Former Jemma Building	A2	186 Granite Street		199411017, Project 5345		Haz Waste	Closed	downgradient
	Former Jemma Building	A2	186 Granite Street		199411017, Project 9774		OPUF	GMP	Target Property not in GMZ, downgradient
	Langer Place	B	55 South Commercial Street		199403010, Project 4744	Avilite Corp., Studio North	LUST	Closed	downgradient
	33 South Commercial Street	D	33 South Commercial Street		199801078, Project 7585	Manchester Knitted Fashion, A.W. Rose Construction	OPUF	Closed	downgradient
	33 South Commercial Street	D	33 South Commercial Street		na	E & R Cleaners	EDR Historical Cleaners	na	former or current dry cleaning facility downgradient
	Next Level Performance Building	D	31 South Commercial Street		200910035, Project 22572		Haz Waste	SI requested	downgradient, halogenated VOC VI hazard
	Manchester Tobacco Co.	E	64 Granite Street		198903058, Project 755		LUST	Closed	upgradient
	Hermsdorf Fixture Manufacturing Co.	E27	108 Franklin Street		199407080, Project 20532	Ultra, Gamache Enterprises	ETHER	non-permit monitoring	upgradient, VOC contamination below VI threshold
	Hermsdorf Fixture Manufacturing Co.	E27	108 Franklin Street		199407080, Project 20267	Ultra, Gamache Enterprises	Unsolicited Site Assessment	Closed	

TABLE 2

Summary of Contaminated Sites - Potential Construction Target Properties

N.H. Capitol Corridor Rail and Transit Alternatives

Target Property	Contaminated Sites								
	Site Name	EDR Detail Map Identifier	Site Address	Federal Identifiers	State Identifiers	Alternate Names	Site Type	Status	Comments
Granite and Canal Streets	Former Tri-State Amusement Co.	H40	494 Elm Street		200012008, Project 10573		OPUF	Closed	upgradient
	Former Rockwell Automation	H	460 Elm Street		200407074, Project 26023		Haz Waste	no monitoriing currently required	upgradient, halogenated VOC contamination in site groundwater orginating offsite upgradient, below VI threshold
	Former Rockwell Automation	H	460 Elm Street		200407074, Project 13722		Initial Response Spill Site	Closed	
	Queen City Taxi	I	560 Elm Street		199507005, Project 5836		UIC	Closed	
	Former Manchester Tire and Battery	I	570 Elm Street		199002002, Project 14383	Afshin Convenience, Inner City Auto Repair	Haz Waste	GMP	upgradient, monitored under Project 1596
	Former Manchester Tire and Battery	I	570 Elm Street		199002002, Project 1596	Afshin Convenience, Inner City Auto Repair	LUST	GMP	upgradient, petroleum VOCs below VI threshold, Target Property not in GMZ, unlikely to impact Target Property
	Manchester Civic Center	K	599 Elm Street		200005022, Project 10015		Haz Waste	GMP	upgradient, halogenated VOCs above VI threshold, approx. l,000 ft. from Targat property, Target Property not in GMZ, unlikely to impact Target Property
	other sites are unlikely to impact the Target Property due to distance, nature of the release, and/or hydrologic setting								
Spring and Canal Street	Service Master Site	D21	500 North Commercial Street		201003003, Project 23669		Initial Response Spill Site	Closed	downgradient
	JCM Management	E26	540 North Commercial Stret		199307019, Project 23463	Kyzen corp., 540 North Assoc., JCM, Inc., EPE Corp., Forty-Five North Assoc.	Haz Waste	GMP	downgradient
	JCM Management	E26	540 North Commercial Stret		199307019, Project 4397	Kyzen corp., 540 North Assoc., JCM, Inc., EPE Corp., Forty-Five North Assoc.	LUST	Closed	downgradient
	Morgan Self Storage	F33	400 Bedford Street		200205010, Project 11973	Anchor Electric, Morgan Storage, Anchor Electric co.	Haz Waste	GMP	side to downgradient
	Kered Clothing, Inc.	G37	670 North Commercial Street		na	670 North Commercial Street	LUST	Closed	side to downgradient
	PSNH Hydraulic Spill	H42	40 Dow Street		200601029, Project 15286		Initial Response Spill Site	Closed	upgradient
	Remillard Property	H54	1382 Elm Street		199807072, Project 8312		Initial Response Spill Site	Closed	upgradient
	Target Cleaners	O61	1196 Elm Street		na		**EDR Historical Cleaners	na	former or current dry cleaning facility upgradient
	Manchester Place	I63	1200 Elm Street		199402007, Project 4712		Haz Waste	GMP	upgradient, halogenated VOC contamination in site groundwater, concentrations unknown, Target not in GMZ, site out of compliance with GMP
	New England Telephone Co.	I64	1228-1230 Elm Street		199101023, Project 2621		LUST	Closed	upgradient
	North End Laundry and Dry Cleaning	I73	1231 Elm Street		na		**EDR Historical Cleaners	na	former or current dry cleaning facility upgradient
	Bird Bath Laundromat	I75	1237 Elm Street		na		**EDR Historical Cleaners	na	former or current dry cleaning facility upgradient
	1037-1045 Elm Street	R86	1037-1045 Elm Street		199907059, Project 9291	City of Manchester	OPUF	GMP	upgradient, fuel oil contamination in site groundwater, no VI hazard , Target not in GMZ
	other sites are unlikely to impact the Target Property due to distance, nature of the release, and/or hydrologic setting

	South Commercial Street	I	32 South Commercial Street		198905028, Project 12091	South Commercial Street Mobil	Initial Response Spill Site	Closed	
	South Commercial Street	I	32 South Commercial Street		198905028, Project 1052	South Commercial Street Mobil	LUST	GMP	upgradient, petroleum VOCs, no VI hazard, Target Property not in GMZ, impact to Target Property unlikely
	South Commercial Street	I	32 South Commercial Street		198905028, Project 27181	South Commercial Street Mobil	Unsolicited Site Assessment	Closed	
	Merrimack Cleaners	J	12 Loudon Road	NHD986484111	na		EDR Historical Cleaners	na	former or current dry cleaning facility downgradient
	other sites are unlikely to impact the Target Property due to distance, nature of the release, and/or hydrologic setting								

The EDR Detail Maps are included in Attachment A
*Indicates the Target Property
Sites underlined are discussed in the text
Contaminated Sites: site where contamination is known to exist or has existed in the past
**The historical dry cleaning facilities identified are not necessarily contaminated sites or release sites but are included due to the high-risk significance of halogenated VOCs
VOC: Volatile Organic Compounds, often petroleum or solvent (halogenated) related
AUR: Activity and Use Restriction
GMP: Groundwater Management Permit
VI: Vapor Intrusion
Haz Waste: Hazardous Waste Discharge
LUST: Leaking Underground Storage Tank (petroleum)
OPUF: On-Premises-Use Facility
ADS: Asbestos Disposal Site
na: not available/applicable
MOST: Motor Oil Storage Tank
HWRB: NHDES Hazardous Waste Remediation Bureau
SI: Site Investigation
ETHER: Ether contaminated site.
GW-2: NHDES groundwater vapor intrusion threshold
OCRB: NHDES Oil Remediation and Compliance Bureau
UIC: Underground Injection Control (commonly floor drains not related to septic or sewer systems)
LNAPL: Light Non-Aqueous Phase Liquid, generally floating free-phase petroleum product
LAST: Leaking Aboveground Storage Tank
DOT: U.S. Department of Transportation
HMIRS: Hazardous Materials Incident Reporting System

APPENDICES

Appendix A: Massachusetts Maps and Data
Appendix B: Photographs
Appendix C: NH Natural Heritage Report **(*Internal Use Only – Not for Public Distribution*)**
Appendix D: Agency Correspondence and Meeting Minutes

1.0 Introduction

This report provides information on the existing natural resources within the New Hampshire portion of the New Hampshire Capitol Corridor Rail and Transit Study. The study area for this report, which is referred to as the "project corridor", includes the existing Pan Am Railways rail line and potentially affected areas adjacent to it from Nashua to Concord, New Hampshire.

In preparing this report, The Smart Associates, Environmental Consultants, Inc. (The Smart Associates) collected and reviewed background data and maps, coordinated with natural resource agencies, conducted a brief "windshield" survey of the entire corridor, and completed more detailed field reviews for 11 potential station/layover facilities. This report provides a summary of the natural resources present within the project corridor. Other environmental resources and issues, such as contaminated properties, historic and cultural resources, and socioeconomic concerns are not addressed.

Appendix A provides a brief overview of the Massachusetts portion (Lowell to Tyngsborough) of the Capitol Corridor Rail and Transit Study. Field reviews and extensive data collection were not completed for the Massachusetts portion of the project since the natural resource impacts are anticipated to be minor. Wetland, floodplain, and rare species data obtained from the MassGIS website are included in Appendix A.

2.0 Wetlands

Wetlands are federally protected under the Clean Water Act (CWA) and activities resulting in impacts to them require a permit from the U.S. Army Corps of Engineers (ACOE) under Section 404 of the CWA. Wetlands are also protected under State of New Hampshire statutes, with permits obtained through the New Hampshire Department of Environmental Services (NHDES) Wetlands Bureau. Compensatory mitigation is required for projects that involve 10,000 square feet or more of wetland impact under the New Hampshire statutes.

In New Hampshire, municipalities can chose to designate wetlands as "prime wetlands" (RSA 482-A:15 and administrative rules Env-Wt 700). Prime wetlands are generally considered to be exceptionally valuable because of their large size, undisturbed condition, and ability to support wildlife and provide other functions and values. Some prime wetlands have a 100-foot protected buffer zone. Impacts to prime wetlands and their buffer zones should be avoided if possible. If impacts are necessary, compensatory mitigation is required and a public hearing is required to be held prior to permit approval.

Wetlands along the project corridor were not field-delineated, but were identified using available mapping, such as National Wetland Inventory Maps, the NH Wetlands Base Map, US Geologic Survey (USGS) topographic maps, and aerial photographs.

Field reviews of the proposed station and layover facilities were conducted in order to obtain more accurate information on wetland resources. Approximate wetland boundaries within and adjacent to the proposed facilities were mapped using GPS, but wetland delineation flags were not placed in the field and surveyed. Photographs taken during the field reviews are included in Appendix B.

In order to more accurately evaluate wetland impacts and to apply for ACOE and NHDES permits, a formal wetland delineation within the entire project corridor and the station and layover facilities will need to be conducted during the project's preliminary design phase.

2.1 Summary of Resources – Proposed Rail Corridor

Wetland resources within the project corridor include palustrine and riverine systems that feed into the Merrimack River. Since the proposed rail corridor follows an existing railroad embankment, wetland and stream crossings are currently bridged or culverted. As a result, the wetland systems that are crossed by the rail embankment have already been impacted by the placement of fill and culverts.

Wetlands are scattered along the entire project corridor, although the large wetland systems are generally located outside of densely developed areas (refer to Figures 2-1a to 2-1g). Table 2-1 provides a summary of the large wetland systems that are located along the project corridor.

Prime wetlands within the project corridor are located in the municipalities of Hooksett and Nashua. Prime wetlands are identified in Table 2-1 (Large Wetland Systems) and on Figures 2-1a through 2-1g. Within the City of Nashua, the Merrimack River, the Nashua River, and Salmon Brook are also considered prime wetlands. None of the prime wetlands within the project corridor have a 100-foot buffer zone.

Table 2-1. Large Wetland Systems along Rail Corridor

Town	Federal Classification(s)	Prime Wetland?	Description
Concord	PUBH, PUBF, PEM1F, PSS1E, PFO1E	No	Located near I-93, Exit 12. Includes "South End Marsh" (conservation land owned by the City of Concord) and a NHDOT wetland mitigation area
Bow	PSS/EM1E, PSS1E, PUBHh, PUB/SS1F	No	Located near PSNH facility. Wetland system appears to have been altered by PSNH facility. Bow Bog Brook flows through wetland system.
Hooksett	PSS1E, PUBHh	Yes	Includes wetlands and open water areas located between Route 3A and Merrimack River.
Hooksett	PSS/EM1E	No	Wetland system associated with an unnamed tributary to Merrimack River. Located between Dale Road and Merrimack River.
Hooksett	PSS1E, PUBF	Yes	Wetland system associated with Messer Brook. Located near Hooksett/Manchester town line.
Manchester	PEM1F, PSS/EM1E, PFO/EM1E	No	Wetland system associated with unnamed tributaries to Merrimack River. Located approximately 1 mile north of Amoskeag Street bridge.
Merrimack	L1UBH, PSS1E, PSS1C	No	Horseshoe Pond and associated wetlands. Also includes Naticook Brook
Merrimack	PFO1E, PFO4E, PEM1Eb	No	Located near Mast Road, between Route 3 and Merrimack River
Nashua	R5UBHx, PUB/SS1Fh, PFO1E	Yes	Wetland system associated with Salmon Brook

PUBH = Palustrine, Unconsolidated Bottom, Permanently Flooded
PUBF = Palustrine, Unconsolidated Bottom, Semipermanently Flooded
PEM1F = Palustrine, Emergent, Persistent, Semipermanently Flooded
PSS1E = Palustrine, Scrub-shrub, Broad-leaved Deciduous, Seasonally Flooded/Saturated
PFO1E = Palustrine, Forested, Broad-leaved Deciduous, Seasonally Flooded/Saturated
PSS/PEM1E = Palustrine, Scrub-scrub / Emergent, Persistent, Seasonally Flooded/Saturated
PUBHh = Palustrine, Unconsolidated Bottom, Permanently Flooded, Diked/Impounded
PUB/SS1F = Palustrine, Unconsolidated Bottom / Scrub-shrub, Broad-leaved Deciduous, Semipermanently Flooded
PFO/EM1E = Palustrine, Forested, Broad-leaved Deciduous / Emergent, Persistent, Seasonally Flooded/Saturated
L1UBH = Lacustrine, Limnetic, Unconsolidated Bottom, Permanently Flooded
PSS1C = Palustrine, Scrub-shrub, Broad-leaved Deciduous, Seasonally Flooded
PFO4E = Palustrine, Forested, Needle-leaved Evergreen, Seasonally Flooded/Saturated
PEM1Eb = Palustrine, Emergent, Persistent, Seasonally Flooded/Saturated, Beaver
R5UBHx = Riverine, Unknown Perennial, Unconsolidated Bottom, Permanently Flooded, x = Excavated
PUB/SS1Fh = Palustrine, Unconsolidated Bottom / Scrub-shrub, Broad-leaved Deciduous, Semipermanently Flooded, Diked/Impounded

2.2 Summary of Resources – Station and Layover Facilities

Field reviews were conducted for 11 potential station and layover facilities and the results of these field reviews are described below. Although 11 sites were reviewed in order to collect data and evaluate impacts, only five station sites and one layover facility site will ultimately be selected for the project.

Stickney Avenue Station Site, Concord
No wetlands or watercourses are located within or adjacent to the site, based on a field review conducted in November 2013. The Merrimack River is located approximately 800 feet east of the site.

Bridge Street Station Site, Manchester
No wetlands or watercourses are located within or adjacent to the site, based on a field review conducted in January 2014. The Merrimack River is located approximately 500 feet west of the site.

Granite Street Station Site, Manchester
No wetlands or watercourses are located within or adjacent to the site, based on a field review conducted in November 2013. The Merrimack River is located approximately 700 feet west of the site.

Riverwalk Way Layover Facility Site, Manchester
No wetlands or watercourses are located within or adjacent to the site, based on a field review conducted in March 2014. The Merrimack River is located approximately 600 feet west of the site.

Queen City Bridge Layover Facility Site, Manchester
No wetlands or water courses are located within the site, based on a review of aerial photographs and National Wetland Inventory maps. A field review of the site was not conducted due to limited access. The Merrimack River is located on the west side of the site, approximately 50 to 100 feet from the edge of the site.

Riverdale Avenue Layover Facility Site, Manchester
This site includes forested wetland areas and several intermittent streams. Wetlands were identified during field reviews conducted in January, March, and September 2014. The limits of the field reviews (shown on Figure 2-2) included an approximate 2,300-foot by 250-foot corridor along the east side of the railroad embankment. The Merrimack River is located approximately 100 to 400 feet to the southwest of the railroad embankment.

The southern portion of the site includes a forested wetland that is classified as seasonally flooded/saturated, palustrine forested with broad-leaved deciduous vegetation (PFO1E). This wetland feeds two intermittent streams that flow through the site. One stream channel flows south through the forested wetland and enters a catch basin/drain at the southern edge of the site, which appears to outlet into the Merrimack River. The second stream runs north through the site, then flows southwest through a culvert under the railroad embankment and eventually enters the Merrimack River. In addition, two smaller streams/drainages enter the northern boundary of the site and flow into the main stream channel. These streams have steep banks that range from approximately 3 to 15 feet in height. Except for the forested wetland in the southern portion of the site, the streams are bordered by upland areas.

The northern edge of the site includes a forested wetland system that continues beyond the study area. This wetland is classified as seasonally flooded/saturated, palustrine forested with broad-leaved deciduous vegetation (PFO1E). Evidence of inundation (water-stained leaves, shallow roots, and little herbaceous cover) was noted during the September 2014 field review; however no standing water was present at the

time of the field review. This wetland may potentially serve as a vernal pool since it appears to collect water and it is located away from the intermittent stream systems. A field visit during the spring (March to May) would be necessary to determine if vernal pool indicator species, such as wood frog (*Rana sylvatica*) and spotted salamander (*Ambystoma maculatum*) are present.

Dominant vegetation at this site includes white pine (*Pinus strobus*), oak (*Quercus* sp.), red maple (*Acer rubrum*), oriental bittersweet (*Celastrus orbiculatus*), goldenrod (*Solidago* sp.), and various ferns. Large portions of the site are densely vegetated with Japanese barberry (*Berberis thunbergii*) and burning bush (*Euonymus alatus*), which are both considered invasive species.

Brown Avenue Layover Facility Site, Manchester

No wetlands or watercourses are located within the site, based on a field review conducted in January 2014. A small forested wetland is located adjacent to the southern edge of the site (refer to Figure 2-3). This wetland is located between a residential area and the railroad embankment. The Merrimack River is located approximately 400 feet west of the site.

Raymond Wieczorek Drive (MHT Airport) Park and Ride Station Site, Bedford

Several wetlands and watercourses are located within the site. The site was field reviewed in November and December 2013. The limits of the field review (shown in Figure 2-4) included undeveloped areas located immediately north and south of Raymond Wieczorek Drive and west of the existing railroad embankment. A portion of the site located north of Raymond Wieczorek Drive is currently used for the storage of propane tanks. The Merrimack River is located approximately 200 feet east of the site.

North of Raymond Wieczorek Drive, the majority of the site is forested wetland. Emergent/scrub-shrub wetlands and a small area of open water are located near the railroad embankment. Upland areas include the propane tank facility and the eastern and western edges of the site. An unnamed stream flows through the forested portion of the wetland. The stream had a few inches of flowing water at the time of the field review, but it appears that it may run dry during summer months.

Wetlands within this portion of the site are classified as: seasonally flooded/saturated, palustrine forested with broad-leaved deciduous vegetation (PFO1E); seasonally flooded/saturated, palustrine emergent with persistent vegetation (PEM1E); seasonally flooded/saturated, palustrine emergent/scrub-shrub (PEM1E/PSS1E); and semipermanently flooded, palustrine, unconsolidated bottom (PUBF). Vegetation within the emergent and scrub-shrub wetland areas generally includes common reed (*Phragmites australis*), meadowsweet (*Spiraea latifolia*), cattail (*Typha latifolia*), raspberry (*Rubus idaeus*), goldenrod, and glossy buckthorn (*Frangula alnus*). Vegetation within the forested wetland areas includes red oak, red maple (*Acer rubrum*), cinnamon fern (*Osmundastrum cinnamomeum),* and royal fern *(Osmunda spectabilis)*. White pine is also present along the wetland edges.

South of Raymond Wieczorek Drive, there are two small forested wetlands and one emergent/scrub-shrub wetland. These three wetlands drain to Sebbins Brook, which flows into the Merrimack River. Within the site, the banks of Sebbins Brook are generally 3 to 6 feet in height, although in some areas the banks are much taller (up to 30 feet). Vegetation along the banks generally includes red oak, red maple, and silky dogwood (*Cornus amomum*), along with some highbush blueberry (*Vaccinium corymbosum*) and winterberry holly (*Ilex verticillata*).

Wetlands within the southern portion of the site are classified as seasonally flooded/saturated, palustrine forested with broad-leaved deciduous vegetation (PFO1E) and seasonally flooded/saturated, palustrine emergent/scrub-shrub (PEM1E/PSS1E). The forested wetlands are vegetated with red oak, red maple, and some winterberry holly. Very little herbaceous vegetation was present at the time of the field

reviews. The emergent/scrub-shrub wetland is vegetated with goldenrod, meadowsweet, dogwood, and bittersweet (*Celastrus orbiculatus).*

Crown Street Park and Ride Station Site, Nashua

No wetlands or watercourses are located within or adjacent to the site, based on a field review conducted in December 2013. The Merrimack River is located approximately 1,000 feet east of the site.

Spit Brook Road Layover Facility Site, Nashua

The study area for this site includes the former Hampshire Chemical Property (refer to Figure 2-5). A portion of this property is enclosed by a security fence that prevents access. As a result, the portion of the property located outside the fence was field reviewed, but no field reviews were completed inside the fence. Information on wetland resources inside the fence were obtained from National Wetland Inventory and USGS maps.

One wetland is located in the southern portion of the site, outside of the fenced area. This wetland is classified as seasonally flooded/saturated, palustrine emergent with persistent vegetation and seasonally flooded/saturated, palustrine forested with broad-leaved deciduous vegetation (PEM1E/PFO1E). The emergent portion of the wetland is predominantly vegetated with reed canary grass (*Phalaris arundinacea*). Other vegetation includes purple loosestrife (*Lythrum salicaria*), soft rush (*Juncus effusus*), and blue vervain (*Verbena hastata*), along with some dogwood (*Cornus sp*.) shrubs at the edge of the wetland. The forested portion of the wetland is vegetated with ash (*Fraxinus sp*.), red oak (*Quercus rubra*), aspen (*Populus sp*.), honeysuckle (*Lonicera sp*.), and goldenrod. It appears that the wetland may flood periodically, but the soils were dry at the time of the field reviews (November and December 2013). A channel is present in the forested portion of the wetland, but it did not contain any flowing water at the time of the field reviews. Water appears to flow over a dirt access road (beyond the end of Spit Brook Road) and continue south beyond the project area.

A swale was also noted in the southern portion of the site; however this swale appears to be constructed and did not contain wetland vegetation or evidence of recent flow. As such, the swale does not appear to be a jurisdictional (regulated) wetland.

According to the NWI maps, two small wetlands are mapped inside the fence. These wetlands are located in the northern portion of the study area (refer to Figure 2-5) and are classified as palustrine, unconsolidated bottom, artificially flooded, excavated (PUBKx).

Spit Brook flows through the northern portion of the site and continues into the Merrimack River, which is located just east of the site. Spit Brook flows under Daniel Webster Highway, enters the western edge of the site, and flows through a forested area that appears to contain wetlands. Since access inside the fence was not obtained, the exact location of the stream channel and wetland boundaries could not be identified. According to NWI and USGS maps, it appears that the stream is culverted under the site from the edge of the forested area to the existing railroad embankment. The culvert outlet was not located during field reviews, however, so it is possible that the stream may outlet directly into the Merrimack River.

Pheasant Lane Mall Park and Ride Station Site, Nashua

No wetlands or watercourses are located within the site, based on a field review conducted in January 2014. The Merrimack River is located approximately 50 feet east of the site. Several wetlands and detention basins/stormwater treatment areas are located south of the site, adjacent to the Pheasant Lane Mall parking lot (refer to Figure 2-6).

3.0 Water Quality

3.1 Surface Water Resources

The dominant surface water feature within the project corridor is the Merrimack River which flows from north to south through the entire corridor from Concord to Nashua. The existing rail line parallels the Merrimack River crossing it twice: once in the Town of Hooksett and again from the City of Manchester to the Town of Bedford. Based upon a review of USGS topographic maps and the NHDES Watershed Report Cards[1], the existing rail corridor crosses 25 other rivers or streams between the Massachusetts border and the end of the project study area in Concord. Table 3-1 lists the name of each water body and the municipality in which the crossing is located. The crossing numbers provided in Table 3-1 reference the numbers shown on Figures 2-1a through 2-1g. Two crossings (Baker Brook and Spit Brook) occur in urban areas of Manchester and Nashua, respectively, and flow through culverts instead of natural channels. In addition to the water bodies cited in Table 3-1, Horseshoe Pond in Merrimack and South End Marsh and an unnamed pond in Concord, as well as numerous wetlands are also located within 100 feet of the existing rail line.

[1] Watershed Report Cards are available on the NHDES website (http://des.nh.gov/organization/divisions/water/wmb/swqa/report_cards.htm) and provide information on water quality, including impairments, for each 12 digit Hydrologic Unit Code (HUC12). The Watershed Report Cards that were reviewed for this report were prepared by NHDES using the Draft 2012 305(b)/303(d) Lists.

Table 3-1. Surface Water Crossings

Crossing # (as shown in Figures 2-1a to 2-1g)	Waterbody	Municipality
1	Unnamed tributary to the Merrimack River	Bow
2	Turkey River	Bow
3	Unnamed tributary to the Merrimack River	Bow
4	Bow Bog Brook	Bow

20	Unnamed tributary to the Merrimack River	Merrimack
21	Souhegan River	Merrimack
22	Naticook Brook	Merrimack
23	Pennichuck Brook	Merrimack/Nashua
24	Nashua River	Nashua
25	Salmon Brook	Nashua
26	Unnamed tributary to the Merrimack River	Nashua
27	Spit Brook	Nashua

Surface water quality is regulated statewide by the NHDES under rules found at Env-Wq 1700 and Nationally by the US Environmental Protection Agency (EPA) under the Clean Water Act. The state Surface Water Quality Regulations govern the discharge of potential pollutants to surface waters of the state and specify water quality standards intended to protect aquatic life and human health. State statute RSA-A:8 establishes two classes of surface water: Class A and Class B. Class A is the higher

classification and designates water quality that is uniformly excellent and potentially acceptable for water supply uses after adequate treatment. Discharge of sewerage or waste into Class A waters is prohibited. Class B waters are considered acceptable for swimming, fishing, and water supplies after adequate treatment. In general, discharges to Class B waters are allowed provided that such discharges do not violate established water quality standards. Based upon data supplied by the NHDES, all of the surface waters within the project study area are considered Class B (K. Edwardson, personal communication).

The Clean Water Act requires each state to submit two surface water quality documents to the EPA every two years. Section 305(b) of the Clean Water Act requires the submittal of a report that describes the quality of surface waters and an analysis of the extent to which all such waters provide for the protection and propagation of a "balanced population of shellfish, fish, and wildlife and allow recreational activities in and on the water."

The second document is commonly referred to as the 303(d) List because it is required by Section 303(d) of the Clean Water Act. The 303(d) list identifies segments of rivers, lakes, impoundments, estuaries, and the ocean that do not meet water quality standards for their assigned uses. The impaired segments are identified as "assessment units" that are based upon the type of water body and the watershed in which they are found. The 303(d) List includes all surface waters that are:

- Impaired or threatened by a pollutant or pollutants;
- Not expected to meet water quality standards within a reasonable time even after application of best available technology standards for point sources or best management practices for nonpoint sources; and
- Require development and implementation of a comprehensive water quality study, referred to as a Total Maximum Daily Load (TMDL) study that is designed to facilitate achievement of applicable water quality standards.

Table 3-2 provides a list of all impaired surface waters located within the vicinity of the project corridor. This list includes all surface waters that are either crossed by or located within 100 feet of the existing rail line. Table 3-3 provides a list of all impaired surface waters located within a one-mile radius of the potential station and layover sites. The data shown in these tables were obtained from the Final 2012 "List of Threatened or Impaired Waters that Require a TMDL" and the 2012 Watershed Report Cards obtained from NHDES.

Pursuant to NHDES Regulation Env-Wq 1708.05 surface waters of national forests and surface waters designated as natural under state statute RSA 483:7-a, I are considered Outstanding Resource Waters (ORWs). As such, water quality in these water bodies must be maintained and protected, except "that some limited point source and nonpoint source discharges may be allowed providing that they are of limited activity which results in no more than temporary and short-term changes in water quality." Based upon data obtained from the NHDES OneStop Web Geographic Information System there are no ORWs within the project corridor. Other data on file with Web Geographic Information System identify a single surface water intake within ¼ -mile of the existing rail line, in the town of Merrimack.

Notes: DO saturation = Dissolved oxygen saturation

3.2 Groundwater Resources

Groundwater resources within the project corridor are generally associated with extensive stratified drift aquifers adjacent to the Merrimack River that were formed in glacial Lakes Merrimack and Hooksett (Ayotte, 1995). The transmissivities of these aquifers generally do not exceed 1,000-2,000 ft^2/day, but may locally exceed 4,000 to 6,000 ft^2/day (Ayotte, 1995 & Stekl, 1997). Mapped aquifers included in the NHDES OneStop Web Geographic Information System indicate that virtually the entire project study area, except the urban areas of Manchester is underlain stratified drift aquifers. These aquifers serve as a water supply source for communities, businesses, and private homes. Groundwater resources are regulated by the New Hampshire Groundwater Protection Act of 1991 and the federal Safe Drinking Water Act.

Data included in the Geographic Information System identify 14 public water supplies (4 in the Town of Merrimack and 10 in the Town of Bow) and over 130 groundwater wells within ¼ -mile of the existing rail line. In addition, approximately 2.3 linear miles of the existing rail line passes over portions of the Towns of Bow, Concord, and Merrimack that are classified as Wellhead Protection Areas (WPA) by the NHDES. None of the proposed station or layover areas are located within WPAs.

4.0 Coastal Resources/Shoreland

Coastal Resources include resources protected under the Federal Coastal Zone Management Act and the Coastal Barrier Resources Act. No such resources are located within the project corridor.

This section also includes resources protected under the New Hampshire Shoreland Water Quality Protection Act (SWQPA). The SWQPA (RSA 483-B) applies to all land within 250 feet of the reference line of all lakes, ponds, and impoundments greater than 10 acres in size, all fourth order and larger streams and rivers, tidal waters, and rivers designated under the New Hampshire Rivers Management and Protection Act. Development and vegetation clearing within the protected shoreland is regulated by the NHDES. For rivers, the reference line corresponds to the ordinary high water mark. For lakes, ponds, and artificial impoundments, the reference line is the surface elevation as listed in the "Consolidated List of Waterbodies subject to the Shoreland Water Quality Protection Act", which is published by NHDES.

Several waterbodies within the project corridor are subject to the SWQPA (refer to Table 4-1 and Figure 4-1). These waterbodies were identified by reviewing the current NHDES "Consolidated List of Waterbodies Subject to the Shoreland Water Quality Protection Act". Segments of the existing rail line (approximately 22 miles in total) are located within 250 feet of the Merrimack River and there are two crossings of the Merrimack River. The other waterbodies listed in Table 4-1 are either crossed once by the rail line or border the rail line in one location.

Table 4-1. Waterbodies Subject to NH Shoreland Water Quality Protection Act

Waterbody Name	Town(s)
Merrimack River	Concord, Bow, Hooksett, Manchester, Bedford, Merrimack, Nashua
Turkey River	Bow
Garvins Falls Dam (on Merrimack River)	Concord, Bow
Hooksett Hydro Pond (on Merrimack River)	Hooksett
Amoskeag Dam (on Merrimack River)	Manchester
Souhegan River	Merrimack
Horseshoe Pond	Merrimack
Pennichuck Brook	Merrimack, Nashua
Nashua River	Nashua
Salmon Brook	Nashua

Note: Waterbodies that are located within approximately 250 feet of the existing rail line and the proposed station/layover facilities are included.

5.0 Floodplains

Digital Flood Insurance Rate Maps for the project corridor were obtained from New Hampshire's GRANIT GIS website (www.granit.unh.edu). Since the rail corridor is located along the Merrimack River, a large portion of the project is located within or adjacent to areas that are mapped as 100-year floodplains (refer to Figures 5-1a through 5-1g).

Most of the proposed station and layover facility sites are located within or adjacent to floodplain areas (refer to Figures 5-2 through 5-12). These areas are generally mapped as either "Zone AE" (100-year floodplain or 1 percent annual chance of flood) or "0.2 percent annual chance of flood hazard" (500-year floodplain). Portions of the Downtown Nashua site are mapped as "Zone X, Protected by Levee". Table 5-1 provides information on the floodplain areas located at each potential station and layover facility.

Table 5-1. Floodplains near Station and Layover Facilities

Potential Station/Layover Site	Floodplains
Stickney Avenue Station Site Concord	Site is mapped as 0.2% annual chance of flood hazard.
Bridge Street Station Site Manchester	None
Granite Street Station Site Manchester	None
Riverwalk Way Layover Facility Site Manchester	None
Queen City Bridge Layover Facility Site Manchester	A portion of the northern half of the site is mapped as 0.2% annual chance of flood hazard. Zone AE is mapped just west of the site, along Merrimack River
Riverdale Avenue Layover Facility Site Manchester	None mapped within site. Zone AE is mapped on southwest side of railroad embankment, along Merrimack River
Brown Avenue Layover Facility Site Manchester	None mapped within site. Zone AE is mapped along Merrimack River and 0.2% annual chance of flood hazard zone is mapped over a portion of the wastewater treatment facility.
Raymond Wieczorek Drive (MHT Airport) Park and Ride Station Site Bedford	Portions of site are mapped as either Zone AE or 0.2% annual chance of flood hazard
Crown Street Park and Ride Station Site Nashua	Portions of site are mapped as Zone X, Protected by Levee
Spit Brook Road Layover Facility Site Nashua	Majority of site is mapped as 0.2% annual chance of flood hazard; some areas are mapped as Zone AE.
Pheasant Lane Mall Park and Ride Station Site Nashua	Entire site is mapped as 0.2% annual chance of flood hazard. Zone AE is mapped along Merrimack River at edge of site.

6.0 Wild and Scenic Rivers/NH Designated Rivers

In 1968, the US Congress passed the Federal Wild and Scenic Rivers Act (P.L. 90-542) in order to preserve "certain selected rivers of the Nation which, with their immediate environments, possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values". Currently, there are no river segments within the vicinity of the project corridor that are included in the federal Wild and Scenic Rivers Program.

In 1988, the New Hampshire Legislature passed the Rivers Management and Protection Act (RSA 483) which established a statewide rivers program based on a two-tier approach to river management and protection: 1.) state designation of significant rivers and protection of instream values and 2.) local development and adoption of river corridor management plans to protect shorelines and adjacent lands. Projects located within a ¼ mile of a Designated River require coordination with the River's Local Advisory Committee (LAC).

Several rivers that are designated under the NH Rivers Management and Protection Act are located within a ¼ mile of the project corridor (refer to Table 6-1 and Figure 6-1).

Table 6-1. NH Designated Rivers along Rail Corridor

River	Town(s)
Upper Merrimack River	Concord, Bow
Lower Merrimack River	Merrimack, Nashua
Piscataquog River	Manchester
Souhegan River	Merrimack

Two sections of the Merrimack River (Upper and Lower) were designated under the Rivers Management and Protection Act in 1990. The Upper portion runs through Franklin, Northfield, Boscawen, Canterbury, Concord and Bow. The Lower portion runs through Merrimack, Litchfield, Hudson, and Nashua. The existing rail line is located adjacent to designated segments of the Merrimack River in Concord, Bow, Merrimack, and Nashua. The two Merrimack River crossings, located in Hooksett and Manchester/Bedford, are not within designated river segments.

The Piscataquog River consists of three branches (South, Middle and North), which were all designated under the NH Rivers Management and Protection Act in 1993. The three branches flow through the communities of Deering, Francestown, Lyndeborough, New Boston, Weare, Goffstown, and Manchester. In Manchester, the Piscataquog River flows into the Merrimack River at Bass Island. The existing rail line is located within a ¼ mile of the Piscataquog River, but it is on the opposite side of the Merrimack River.

The Souhegan River was designated in 2000 and includes the communities of New Ipswich, Greenville, Wilton, Milford, Amherst, and Merrimack. The project corridor crosses the Souhegan River near where it flows into the Merrimack River.

7.0 Wildlife, Fisheries, and Natural Communities

7.1 Wildlife Habitat

Information on wildlife habitat within the project corridor was obtained from the New Hampshire Wildlife Action Plan and from field reviews conducted in 2013 and 2014. A variety of habitat types are located within the project corridor, as discussed below. In Concord, Manchester, and Nashua, the existing rail line crosses through developed urban areas that provided limited habitat. Other segments of the rail line cross through undeveloped forested land that provide valuable habitat. The entire study area is located along the Merrimack River, which is an important corridor for migrating birds. Bald eagles spend the winter along the Merrimack River and use large trees along the banks for perching and roosting.

7.1.1 Habitat Types

The following paragraphs provide information on the habitat types found within the project corridor. This information is based on data obtained from the New Hampshire Wildlife Action Plan (NH Fish and Game Department, 2005) and cursory field reviews.

Appalachian Oak Pine Forest – This habitat is scattered throughout the undeveloped portions of the project corridor. It is a habitat type that is found at lower elevations in southern New Hampshire. Soils

are typically nutrient-poor and sandy. A variety of wildlife species use this habitat, such as eastern hognose snake (*Heterodon platirhinos*), whip-poor will (*Antrostomus vociferus*), veery (*Catharus fuscescens*), northern myotis (*Myotis septentrionalis*), white-tailed deer (*Odocoileus virginianus*), and black bear (*Ursus americanus*).

Floodplain Forests – Floodplain forests are located in low areas adjacent to river channels and are characterized by frequent flooding. Since the majority of the existing rail line is located adjacent to the Merrimack River, floodplain forest habitat is scattered throughout the project corridor. Floodplain forests provide breeding habitat for a variety of bird species, such as red-shouldered hawk (*Buteo lineatus*), veery, and Cerulean warbler (*Dendroica cerulean*). Mammal species that are typically associated with this habitat include beaver (*Castor canadensis*) and mink (*Mustela vison*). Floodplain forests also provide important habitat for reptiles and amphibians.

Grasslands – Grasslands include areas that are vegetated predominantly with grasses, forbs, and sedges and have very little tree or shrub cover. They generally include hayfields and pastures, fallow fields, cropland, airports, and landfills. Many of the open areas along the undeveloped portions of the project corridor include grassland habitat, although this habitat type is disperse and the individual blocks of habitat are typically small. Grasslands provide habitat for several rare, threatened, or endangered bird species, including upland sandpiper (*Bartramia longicauda*), grasshopper sparrow (*Ammodramus savannarum*), eastern meadowlark (*Sturnella magna*), and vesper sparrow (*Pooecetes gramineus*). Other rare species that utilize grassland habitat include northern black racer (*Coluber constrictor*), northern leopard frog (*Rana pipiens*), and wood turtle (*Glyptemys insculpta*).

Hemlock Hardwood Pine Forest – This is the most common forest habitat in New Hampshire and covers almost 50% of the state. Vegetation generally includes white pine (*Pinus strobus*), eastern hemlock (*Tsuga canadensis*), American beech (*Fagus grandifolia*), and oak (*Quercus* sp.). Within the project corridor, this habitat type occupies large portions of the undeveloped forested areas. A variety of species are associated with this habitat, including northern goshawk (*Accipiter gentilis*), veery, Cerulean warbler, northern myotis, white-tailed deer, and black bear.

Marsh and Shrub Wetlands – This habitat type includes emergent and scrub-shrub wetlands that are found throughout the project corridor, as discussed in Section 2.0. Many wildlife species use this habitat type, including red-winged blackbird (*Agelaius phoeniceus*), beaver, painted turtle (*Chrysemys picta*), and great blue heron (*Ardea herodias*). This habitat also supports rare species such as Blanding's turtle (*Emydoidea blandingii*), New England cottontail (*Sylvilagus tranisitionalis*), and spotted turtle (*Clemmys guttata*).

Talus Slopes and Rocky Ridges – Talus slopes include areas of boulders or rocks while rocky ridges are characterized by shallow bedrock or rock outcrops. According to the New Hampshire Wildlife Action Plan, this habitat type is found in one segment of the project corridor located north of Martins Ferry Road/Depot Road in Hooksett. Rare species that may be associated within this habitat type include timber rattlesnake (*Crotalus horridus*) and bobcat (*Lyns rufus*).

Shrublands – Shrubland habitat includes areas dominated by shrubs with scattered forbs, ferns, and grasses. These habitats often include disturbed areas such as power line rights-of-way and old agricultural fields. Within the project corridor, shrubland habitat can be found in areas adjacent to the existing rail line and at power line crossings. Shrubland habitat is declining in New Hampshire and is associated with rare species such as New England cottontail, northern black racer, and wood turtle. Other species that inhabit shrublands include ruffed grouse (*Bonasa umbellus*) and woodcock (*Scolopax minor*).

7.1.2 Habitat Value

The New Hampshire Wildlife Action Plan was reviewed to obtain information on habitat value within the project corridor. The Wildlife Action Plan provides a ranking of habitat condition for the entire state. The ranking is based on biological, landscape, and human impact factors. Biological factors include rare plant and animal species and overall biodiversity. Landscape factors include the size of the habitat and its proximity to other habitats. Human impact factors include considerations such as road density, pollution, and recreational use. Sixteen habitat types were assessed as part of the Wildlife Action Plan. The higher-value habitat areas are ranked as follows:

- "Highest Ranked Habitat in New Hampshire" includes the top 15% by area of each forest habitat type and the top 10% by area of other habitat types. Habitat areas for critically imperiled species are also included as highest ranking in the state.
- "Highest Ranked Habitat in Region" includes the top 15% by area of forests and the top 50% by area of other terrestrial habitats within each ecoregion of New Hampshire. A similar method was also used to rank surface water, floodplain, and wetland areas.
- "Supporting Areas" consist of habitats that are necessary to keep the highest ranked habitats in good condition and includes upland areas near surface waters, along with some intact forest blocks and exemplary natural communities.

The existing rail line crosses through "Highest Ranked Habitat" in various locations (refer to Figure 7-1). Table 7-1 provides a summary of the habitat value by municipality. Table 7-2 provides information on wildlife habitat for the potential station and layover facilities.

Table 7-1. Habitat Value along Rail Corridor

Municipality	Habitat Value
Concord	No Highest Ranked Habitat in NH is located within the project corridor. The area near the "South End Marsh" is mapped as Highest Ranked Habitat in Region. Other areas along the existing rail line are mapped as Supporting Areas.
Bow	Most of the project corridor in Bow is mapped as either Highest Ranked Habitat in NH or Supporting Area.
Hooksett	A few areas along the Merrimack River are mapped as Highest Ranked Habitat in NH, including the existing rail line crossing. Other locations are mapped as Highest Ranked Habitat in Region or Supporting Area, but these areas are scattered.
Manchester	Most of the Merrimack River in Manchester is mapped as Highest Ranked Habitat in NH and some areas adjacent to the river are mapped as either Highest Ranked in Region or Supporting Area. The existing rail line is located within these higher ranked habitat areas particularly in the southern part of Manchester. The rail line crossing of the Merrimack River at the Manchester-Bedford town line is located within an area that is mapped as Highest Ranked Habitat in NH.
Bedford	The majority of the project corridor in Bedford is mapped as Highest Ranked Habitat in NH. This habitat is associated with the Merrimack River.
Merrimack	The existing rail line crosses through an area mapped as Highest Ranked Habitat in NH between Horseshoe Pond and Pennichuck Brook. Other small segments of the project corridor are mapped as Highest Ranked Habitat in Region or Supporting Area.
Nashua	One isolated area mapped as Highest Ranked Habitat in NH is located adjacent to the existing rail line near the outlet of the Nashua River. Other locations are mapped as Highest Ranked Habitat in Region or Supporting Area, but these areas are scattered.

Note: Data obtained from NH Wildlife Action Plan Highest Ranking Condition Habitat Maps.

Table 7-2. Habitat Value at Potential Station and Layover Facilities

Potential Station/Layover Site	Habitat Value
Stickney Avenue Station Site Concord	The site is not mapped as Highest Ranking Habitat or as a Supporting Area. Most of the site is currently developed and includes buildings and parking lots. No wildlife was observed during a site visit.
Bridge Street Station Site Manchester	The site is not mapped as Highest Ranking Habitat or as a Supporting Area, although Highest Ranked Habitat is NH is located west of the site along the Merrimack River. The site is located in downtown Manchester and is surrounded by development. Wildlife observations during a site visit included American crow (*Corvus brachyrhynchos*)
Granite Street Station Site Manchester	The site is not mapped as Highest Ranking Habitat or as a Supporting Area, although Highest Ranked Habitat is NH is located west of the site along the Merrimack River. The site is located in downtown Manchester and is surrounded by development. No wildlife was observed during a site visit.
Riverwalk Way Layover Facility Site Manchester	The site is not mapped as Highest Ranking Habitat or as a Supporting Area, although Highest Ranked Habitat is NH is located west of the site along the Merrimack River. The site is located in downtown Manchester and is surrounded by development. No wildlife was observed during a site visit.
Queen City Bridge Layover Facility Site Manchester	The entire site is mapped as Highest Ranked Habitat in NH, due to its proximity to the Merrimack River. The majority of the site is currently developed, although a small forested area is located in the northern portion of the site.
Riverdale Avenue Layover Facillity Site Manchester	The entire site is mapped as either Highest Ranked Habitat in NH or Highest Ranked Habitat in Region. With the exception of the existing rail line, the site is currently undeveloped and includes forested upland and wetland areas. Wildlife observations during site visits included a variety of songbirds and white-tailed deer scat and tracks.
Brown Avenue Layover Facility Site Manchester	The site is located adjacent to Highest Ranked Habitat in NH that is mapped along the Merrimack River. The site itself is mapped as a Supporting Area, but it is currently developed and doesn't appear to provide much habitat. Wildlife noted during a site visit included ducks in the wastewater treatment facility pools.
Raymond Wieczorek Drive (MHT Airport) Park and Ride Station Site Bedford	The entire site and the adjacent area along the Merrimack River are mapped as Highest Ranked Habitat in NH. The undeveloped portions of the site generally consist of forested wetland and upland areas that provide quality habitat. Wildlife observed during site visits included a variety of songbirds and mallard ducks (*Anas platyrhynchos*).
Crown Street Park and Ride Station Site Nashua	The site is not mapped as Highest Ranking Habitat or as a Supporting Area. Most of the site is currently developed and includes buildings and pavement. No wildlife was observed during a site visit.

Table 7-2. Habitat Value at Potential Station and Layover Facilities (continued)

Potential Station/Layover Site	Habitat Value
Spit Brook Road Layover Facility Site Nashua	The site is not mapped as Highest Ranking Habitat or as a Supporting Area. The site is an open field that provides habitat although there are known contamination issues. Wildlife observed during field reviewed included red-tailed hawk (*Buteo jamaicensis*), white-tailed deer, and various songbirds.
Pheasant Lane Mall Park and Ride Station Site Nashua	The site is not mapped as Highest Ranking Habitat or as a Supporting Area. Although the site is located adjacent to the Merrimack River, most of the surrounding area is developed. No wildlife was observed during a site visit.

Note: Data obtained from NH Wildlife Action Plan Highest Ranking Condition Habitat Maps and from site visits conducted by The Smart Associates, Environmental Consultants, Inc. in 2013-2014.

7.2 Fisheries

The perennial streams crossed by the existing rail line likely provide habitat for fish and other aquatic organisms. A field survey of the existing culvert and bridge crossings was not conducted; however it is possible that the current structures could be hindering the movement of aquatic organisms.

Fish species that can be found in the Merrimack River and its perennial tributaries include yellow perch (*Perca flavescens*), chain pickerel (*Esox niger*), small mouth bass (*Pomoxis nigromaculatus*), large mouth bass (*Micropterus salmoides*), and American eel (*Anguilla rostrata*), among others (Nashua Regional Planning Commission, 2008)

The Merrimack River, as well as several of its tributaries, is designated as Essential Fish Habitat (EFH) for Atlantic salmon (*Salmo salar*). The Magnuson-Stevens Fishery Conservation and Management Act requires the federal government to identify EFH and make conservation recommendations to agencies whose actions could damage it. EFH is defined as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity."

Atlantic salmon were extirpated in the Merrimack River in the early 1800's by the construction of dams in Lawrence and Lowell, Massachusetts which blocked their upstream migration from the Atlantic Ocean. Salmon are currently stocked by the New Hampshire Fish and Game Department (NHF&G) and the U.S. Fish and Wildlife Service at several locations in the Merrimack River watershed as part of the Merrimack River Anadromous Fish Restoration Program (NH Fish and Game Department, 2014). Other anadromous fish species that are beginning to return to the Merrimack River include blueback herring (*Alosa aestivalis*), alewife (*Alosa pseudoharengus*), and American shad (*Alosa sapidissima*) (Nashua Regional Planning Commission, 2008).

In addition to the Merrimack River, the following perennial streams within the project corridor are identified as EFH for Atlantic salmon: Turkey River, Bow Bog Brook, Dalton Brook, Messer Brook, Rays Brook, Baker Brook, Sebbins Brook/Pointer Club Brook, Souhegan River, and Nashua River. Of these streams, the Merrimack River, the Souhegan River, and the Nashua River are considered of greater importance with regard to Atlantic salmon restoration efforts (US Army Corps of Engineers, 2012).

7.3 Threatened and Endangered Species

Endangered species are provided protection on both federal and state levels. The Federal Endangered Species Act of 1973 (16 USC 1531-1543, Sec. 2A) is the federal legislation that provides protection, while the State of New Hampshire protects species through the Native Plant Protection Act of 1987 and the New Hampshire Endangered Species Conservation Act of 1979.

The New Hampshire Natural Heritage Bureau (NHB) was contacted in February 2014 to obtain information on rare, threatened, and endangered plant and animal species within the vicinity of the project corridor. The response received from NHB is included in Appendix C. Table 7-3 provides a summary of the species that are present.

NHB also provided information on exemplary natural communities that occur within the project corridor (refer to Table 7-4 and Appendix C). Exemplary natural communities include rare natural communities as well as more common natural communities that are undisturbed or are of high quality. Natural communities are generally characterized by plant species composition, vegetation structure, and physical conditions (e.g. water, climate, nutrient levels) (Sperduto and Nichols, 2010).

A meeting was held with NHF&G and NHB on March 7, 2014 to present the project and discuss potential issues regarding listed species and exemplary natural communities (refer to Appendix D for meeting minutes). During this meeting, the following recommendations were provided by NHF&G and NHB:

- Existing perennial stream culverts should be updated to comply with the NHDES stream crossing rules to allow for fish & wildlife passage.
- Nesting and roosting sites for bald eagles are located along the Merrimack River. NHF&G mentioned that there could be mortality issues with bald eagles and faster train speeds. Other impacts could result from vegetation clearing along the Merrimack River.
- New Hampshire Audubon (Chris Martin) should be contacted to obtain more information on primary foraging areas used by the peregrine falcons that nest in the Brady-Sullivan building in downtown Manchester.
- Expansion of the rail corridor in Bow could have impacts on Eastern hognose snake. Field surveys would likely be required.
- Field surveys in key locations along the rail corridor would likely be needed for New England cottontail.
- A spring field survey at the Spit Brook Road Layover Facility Site in Nashua is recommended for grasshopper sparrow since the large open field may provide habitat for this species.
- Field surveys to determine the extent of the rare plant species and exemplary natural communities listed in Tables 7-3 and 7-4 are recommended by NHB.

More details on the existing rail line, the proposed improvements, and vegetation clearing will be needed for NHF&G and NHB to provide more detailed comments. It is recommended that continued coordination with these agencies occur during the design phases of the project to obtain feedback and to determine the need for any field surveys.

Table 7-3. Rare, Threatened, and Endangered Species

Protected Species	Legal Status		Last Reported	Town(s)
	State	Federal		
Invertebrate Species				
Brook Floater (*Alasmidonta varicosa*)	Listed Endangered	Not listed	2004	Manchester
Plant Species				
Clasping Milkweed (*Asclepias amplexicaulis*)	Listed Threatened	Not listed	2009	Hooksett
Golden Heather (*Hudsonia ericoides*)	Listed Endangered	Not listed	1985	Hooksett
Houghton's Umbrella Sedge (*Cyperus houghtonii*)	Listed Endangered	Not listed	1989	Concord
Licorice goldenrod (*Solidago odora*)	Listed Endangered	Not listed	2003	Hooksett
Northern blazing star (*Liatris novae-angliae*)	Listed Endangered	Not listed	2012	Hooksett
Wild lupine (*Lupinus perennis*)	Listed Threatened	Not listed	1995-2011 (depending on location)	Hooksett, Concord, Merrimack
Vertebrate Species				
Bald Eagle (*Haliaeetus leucocephalus*)	Listed Threatened	Not listed	2006-2013	Manchester, Concord, Bedford
Banded Sunfish (*Enneacanthus obesus*)	Special Concern	Not listed	2005 1938 (Merrimack location)	Manchester, Merrimack
Blanding's Turtle (*Emydoidea blandingii*)	Listed Endangered	Not listed	2010	Merrimack
Eastern Hognose Snake (*Heterodon platirhinos*)	Listed Endangered	Not listed	2003-2012 (depending on location)	Londonderry, Bow, Merrimack
New England Cottontail (*Sylvilagus transitionalis*)	Listed Endangered	Not listed	2002	Merrimack, Bedford, Bow
Northern Leopard Frog (*Rana pipiens*)	Special Concern	Not listed	2004-2006	Concord, Litchfield
Pied-billed Grebe (*Podilymbus podiceps*)	Listed Threatened	Not listed	1988	Concord
Spotted Turtle (*Clemmys guttata*)	Listed Threatened	Not listed	1988	Concord
Swamp Darter (*Etheostoma fusiforme*)	Special Concern	Not listed	2005	Hooksett
Vesper Sparrow (*Pooecetes gramineus*)	Special Concern	Not listed	2002	Merrimack
Wood Turtle (*Glyptemys insculpta*)	Special Concern	Not listed	2010-2012 (depending on location)	Bow

APPENDIX A

Massachusetts Maps and Data

APPENDIX A – MASSACHUSETTS MAPS AND DATA

Wetlands and Surface Waters

In Massachusetts, wetlands are federally regulated under the Clean Water Act and activities resulting in impacts to them require a permit from the U.S. Army Corps of Engineers (ACOE) under Section 404 of that same Act. Wetlands are also regulated at the state-level by the Wetlands Protection Act (WPA), which is administered by the municipal conservation commissions, with overview by the Massachusetts Department of Environmental Protection (MassDEP). The regulations (310 CMR 10.00) implementing the Wetlands Protection Act (*M.G.L. c. 131 s.40)* govern both inland and coastal wetlands, as well as floodplain and Riverfront Areas. The regulations identify "Areas Subject to Protection Under the Act" for which locally issued permits are required including any activity that involves filling, dredging, removing, or altering these areas. Areas subject to protection under the WPA within the project corridor include the following resource areas:

- Banks;
- Bordering Vegetated Wetlands;
- Land Under Water Bodies and Waterways;
- Land Subject to Flooding (Bordering and Isolated Areas); and
- Riverfront Area.

Banks include naturally occurring banks and beaches that are located between a waterbody and a Bordering Vegetated Wetland, floodplain, or upland. They can be vegetated or comprised of exposed soil or rock. Banks are generally significant for groundwater supply, flood control, storm damage prevention, pollution prevention, and for fish and wildlife habitat.

Bordering Vegetated Wetlands include wet meadows, marshes, swamps, bogs, and other freshwater wetlands that border on streams, rivers, ponds, and other surface waters. Boundaries are delineated based on vegetation, soils, and the presence of wetland hydrology. Bordering vegetated wetlands are important for groundwater supply, flood control, storm damage prevention, pollution prevention, wildlife habitat, and fisheries.

Land Under Waterbodies and Waterways is defined as "the bottom of, or the land under, the surface of the ocean or any estuary, creek, river, stream, pond, or lake." The boundary of Land Under Water Bodies and Waterways is the mean annual low water level. Land Under Waterbodies and Waterways is important for groundwater supply, public and private water supply, flood control, storm damage prevention, pollution prevention, wildlife habitat, and fisheries. Work within Land Under Water Bodies and Waterways should not impact the water carrying capacity within the defined channel, groundwater and surface water quality, fisheries, or wildlife habitat.

Bordering Land Subject to Flooding is defined as "an area with low, flat topography adjacent to and inundated by flood waters rising from creeks, rivers, streams, ponds, or lakes." It extends from the banks of the waterway or water body. If a bordering vegetated wetland occurs, then it extends from the edge of the wetland. Isolated land subject to flooding is defined as "an isolated depression or a closed basin without an inlet or an outlet." Land Subject to Flooding is important for flood control and storm damage prevention. Work that will impact Land Subject to Flooding may require mitigation that would compensate for a loss in flood storage. In addition, the work should not impact important wildlife habitat.

A Riverfront Area is defined as "the area of land between a river's mean annual high water line and a parallel line measured horizontally. The riverfront area may include or overlap other resource areas or their buffer zones. Riverfront areas are important for the protection of private and public water supplies, groundwater supply, flood control, storm damage prevention, pollution prevention, and the protection of wildlife habitat, fisheries, and shellfish. The regulated Riverfront Area is generally 200 feet wide except for the following locations, in which the Riverfront Area is 25 feet wide:

- Municipalities with a population of 90,000 people or more;
- Municipalities with a population density of greater than 9,000 people per square mile;
- Areas designated by the Secretary of the Executive Office of Environmental Affairs as a "densely developed area"; and
- Certain identified land within Waltham and Milton (see Section 18, "riverfront area", in the Rivers Protection Act).

The buffer zones adjacent to some resource areas are also protected under the Wetland Protection Act. Within the project corridor, buffer zones include areas within 100 feet from the boundary of any bordering vegetated wetland or bank.

The main surface water feature located along the project corridor is the Merrimack River. Protected resource areas that are associated with the Merrimack River include Land Under Water Bodies and Waterways, Bank, Bordering Land Subject to Flooding, and Riverfront Area. In Tyngsborough and Chelmsford, the Riverfront Area is 200 feet wide and in Lowell the Riverfront Area is 25 feet wide. The majority of the proposed new rail in Tyngsborough is located within the 200-foot Riverfront Area. In Chelmsford, approximately 1 mile of the proposed new rail is located within the 200-foot Riverfront Area. The proposed new rail in Lowell is located beyond the 25-foot Riverfront Area.

Other wetland and water resources crossed by the project corridor include:

- Unnamed tributary to the Merrimack River and adjacent wetlands – located north of Parlee Farms in Tyngsborough;
- Bridge Meadow Brook - located north of the Route 3A bridge over the Merrimack River in Tyngsborough;
- Unnamed tributary to the Merrimack River (flows from Uptons Pond) – located in Tyngsborough near intersection of Route 3A and Westford Road;
- Deep Brook and adjacent wetlands - located in Chelmsford near Wotton Street;
- Stony Brook and adjacent wetlands - located in Chelmsford near Church Street;
- Black Brook - located in Lowell near the intersection of Middlesex Street and Pawtucket Street and appears to be piped under the project corridor and the surrounding urban area;
- Pawtucket Canal – located in Lowell and is crossed twice by the project corridor; and
- River Meadow Brook – located in Lowell near the Lowell Connector and the southern end of the project corridor.

Figures A-1 and A-2 show the locations of wetlands and surface waters. These maps were prepared using the MassDEP Wetlands datalayer downloaded from the MassGIS website.

The project corridor is not located near any Outstanding Resource Waters, as designated by the Massachusetts Surface Water Quality Standards (314 CMR 4.00)

Floodplains

The Digital Flood Insurance Rate Maps (DFIRMs) available on the MassGIS website were reviewed to determine the locations of flood hazard areas within the project corridor (refer to Figures A-3 and A-4).

The project corridor crosses through the 100-year floodplain (Zones A and AE) in several locations. These floodplains are associated with the Merrimack River and its larger tributaries (Deep Brook, Stony Brook, Pawtucket Canal, and River Meadow Brook). The largest Zone A floodplain area is located in Chelmsford, where approximately 1 mile of proposed new rail is located within an area mapped as Zone A floodplain.

In addition to the Zone A and Zone AE floodplains described above, large portions of the project corridor are located within areas mapped as "0.2 percent annual chance of flood hazard", which corresponds to the 500-year floodplain.

Wildlife Habitat and Rare Species

Endangered species are protected at the federal level by the Endangered Species Act of 1973 (16 USC 1531-1543, Sec. 2A) and at a state level by the Massachusetts Endangered Species Act (M.G.L. c.131A). The Massachusetts Natural Heritage and Endangered Species Program (NHESP) is the state agency that is responsible for the protection of plant and animal species that are listed as threatened, endangered, and of special concern in Massachusetts.

Information on important wildlife habitat and recorded occurrences of rare, threatened, and endangered species was obtained from the MassGIS website. Data reviewed included:

- NHESP Priority Habitats of Rare Species – Under the Massachusetts Endangered Species Act (MESA) areas that are important for the protection of state-listed species are identified as Priority Habitat of Rare Species ("Priority Habitat"). Priority Habitat is defined as "the geographic extent of habitat for state-listed species". Projects or activities that occur within a Priority Habitat require review under MESA and consultation with the NHESP.
- NHESP Estimated Habitats of Rare Species – Estimated Habitat of Rare Species ("Estimated Habitat") is a sub-set of Priority Habitat and includes the geographical extent of habitat of state-listed rare wetlands wildlife. These areas are protected by both MESA and the Massachusetts WPA.
- NHESP Certified Vernal Pools – Vernal pools provide important breeding habitat for amphibian and invertebrate species. NHESP Certified Vernal Pools include vernal pools that have been reviewed and certified by NHESP according to the Massachusetts Division of Fisheries and Wildlife's *Guidelines for Certification of Vernal Pool Habitat*.
- NHESP Potential Vernal Pools – The Potential Vernal Pool data that was reviewed includes the locations of potential vernal pools that have been identified using aerial photography. These potential vernal pools have not been certified by NHESP and field review is necessary to verify if a vernal pool exists.

Within the project corridor, the Merrimack River is identified as both Priority Habitat and Estimated Habitat. The existing rail line crosses through or is located adjacent to these designated areas in several locations.

Seven potential vernal pools are mapped within the vicinity of the project corridor in Tyngsborough and Chelmsford. Field reviews would be necessary to confirm if these areas are indeed vernal pools. No certified vernal pools are located in the vicinity of the project corridor.

The project corridor is not located within any Areas of Critical Environmental Concern (ACECs). ACECs are areas in Massachusetts "where unique clusters of natural and human resource values exist, which are worthy of a high level of concern and protection" (301 CMR 12.3). ACEC are nominated at the community level and designated at the state level.

A meeting was held with NHESP on August 13, 2014 to present the project and discuss potential issues regarding listed species (refer to Appendix D for meeting minutes). NHESP identified three species of concern within the project corridor, including bald eagle (*Haliaeetus leucocephalus*), riverine clubtail (*Stylurus amnicola*), and cobra clubtail (*Gomphus vastus*).

Bald eagle is listed as threatened in Massachusetts but is not federally listed. Bald eagles forage along the Merrimack River in the project corridor. NHESP recommended retaining large trees within the project corridor if possible.

Riverine clubtail and cobra clubtail are two species of dragonfly. Riverine clubtail is listed as endangered and cobra clubtail is listed as special concern in Massachusetts. Neither species is federally listed. Potential impacts to these species could occur from the conversion of vegetation or loss of vegetation structure as well as from water quality degradation.

More details on the existing rail line, the proposed improvements, and vegetation clearing will need to be provided to NHESP as the project design progresses. The project will need to be reviewed under the Massachusetts Endangered Species Act (MESA) and an application will need to be filed with NHESP.

Date: Wednesday, February 26, 2014 10:17 AM
To: "'Jennifer Riordan'" <jriordan@smartenvironmental.com>
Subject: RE: NHB review: NHB14-0614

Hi Jenn,
We would recommend updated surveys for all the species and communities that you highlighted in the table. Plus, I would add the clasping milkweed, and pitch pine-scrub oak woodland (both in Hooksett, not highlighted on your list) to the list of elements to survey. Surveys would have to occur during the growing season (May-August).

Updated survey information will help us to better understand the existing population and the potential for impacts. Once this data is collected we would need to meet discuss the details of the project in the sensitive areas and figure out how best to avoid and minimize impacts to rare plants and exemplary natural communities.

Best,
Melissa

Subject: Fw: NHB review: NHB14-0614

Hi Melissa,

Thanks for sending the review memo. This email is to follow-up regarding the plants and natural communities located within the project corridor. The project is the NH Capitol Corridor Rail and Transit Study, which is a planning study of potential rail and bus transit improvements between Boston, MA and Concord, NH. The rail improvements would follow an existing rail corridor. Throughout most of the corridor, the existing rail embankment is wide enough to allow for the addition of a rail line, so impacts should be limited to the existing embankment. Stations and layover facilities would be located at several sites in Nashua, Manchester, Bedford, and Concord. The construction of the station and layover facilities would involve impacts beyond the existing rail embankment.

I reviewed your memo and made some notes on the locations of the species records relative to the rail corridor (see attached table). The species and communities highlighted in green appeared to be the ones with the greatest potential for impacts. The other species/communities are historical records or are located further from the rail corridor (on the opposite side of the Merrimack River, for example).

At this point, we are preparing a technical report that will summarize the natural resources present. A
~~~~~~

NEPA document will also eventually be prepared. Any information on potential impacts, required field surveys, etc. would be helpful to include in the technical report.

Please let me know if you need any further information on the project or would like to discuss on the phone or in person.

Thanks,

Jenn

New Hampshire Capitol Corridor Rail and Transit Study

Meeting with NH Fish and Game Department and NH Natural Heritage Bureau

3/7/14, 9:30 AM – 11:00 AM
Location: NH Fish and Game Headquarters, Concord

Attendees:

Kim Tuttle, NH Fish and Game Department (NH F&G)
Mike Marchand, NH F&G
Heidi Holman, NH F&G
Melissa Coppola, NH Natural Heritage Bureau (NHB)
Carl Chamberlin, URS Corporation (URS)
Jennifer Riordan, The Smart Associates

Minutes:

- Project Overview
  - Carl Chamberlin (URS) provided an overview of the project, which involves the analysis of various transit investments between Boston, MA and Concord, NH. The investments could include expanded bus service and/or new commuter rail service. Three alternatives for rail service are being considered:
    - Commuter Rail to Nashua only
    - Commuter Rail to Manchester, Manchester Airport, and Nashua
    - Intercity rail to Concord, Manchester, Manchester Airport, and Nashua
  - Although expanded bus service is also being considered under this project, most of the impacts to natural resources would result from the rail improvements, particularly the construction of new station and layover facilities.
  - URS was hired by the Federal Transit Administration (FTA) and the Federal Railroad Administration (FRA) to evaluate a full range of alternatives. URS' study will be completed in 2014.
  - 2020 is the earliest that the rail service would begin.
  - Additional information on the project is available at: http://www.nhcapitolcorridor.com/
  - Questions asked:
    - Mike Marchand (NH F&G) asked if there is existing rail along the entire corridor. C. Chamberlin replied that there is single-track rail to Concord. Some portions of the rail corridor will be upgraded to two tracks.
    - Melissa Coppola (NHB) asked if there is a standard width that the rail embankment will need to be widened. C. Chamberlin replied that there is no standard width. Some of the existing bridges may need minor rehab to accommodate a second track. Bridge replacement is not currently proposed.
    - M. Marchand mentioned that the I-93 Expansion Project widened I-93 away from the median to leave space for a potential rail corridor within the median. This resulted in some extensive wetland impacts. M. Marchand asked if a rail corridor in the I-93 median is being considered as an alternative. C. Chamberlin replied that although there is an existing rail ROW along I-93, the rail is no longer there and would require more significant investment than the rail corridor being proposed for this project. As a result, the I-93 rail corridor is not

included as alternative due to cost issues. M. Marchand recommended documenting these cost considerations in the NEPA Environmental Assessment
        - M. Marchand asked if the project has been presented at a DOT Natural Resource Agency Coordination Meeting. C. Chamberlin said that they are planning to attend the April meeting.
        - M. Marchand asked how fast the trains will go. The maximum speed would be 70 miles per hour, with slower speeds through cities. The freight trains that currently use the rail corridor go approximately 10 to 30 (40 max) miles per hour.
- <u>Proposed Station & Layover Facilities</u>
    - The proposed stations would be one of two types:
        - "Park and ride" style would consist of a platform and parking area.
        - "Transit-oriented development" (TOD) style would consist of a platform only.
    - Concord Station – Stickney Ave.
        - "Park and ride" style station
        - Would also function as a layover facility
        - New England cottontail could be a concern along the rail corridor in Concord.
    - Manchester – Bridge St.
        - TOD style station
        - Brady-Sullivan building is located a few blocks to the south.
    - Manchester – Granite St.
        - TOD style station
    - Manchester – Riverwalk Way (near Fisher Cats baseball stadium)
        - Layover facility
    - Manchester – near cemetery
        - Layover facility
        - Located near Carthagina Island, on east bank of Merrimack River
        - Potential exemplary natural community and threatened/endangered species issues
    - Manchester – near Wastewater Treatment Facility and I-293
        - Layover facility
    - Manchester Airport
        - "Park and ride" style station
        - Would be located on west bank of Merrimack River, near Ray Wieczorek Drive.
        - A bald eagle mitigation site (preserved as part of the Manchester Airport Access Road project) is located north of the site, along the Merrimack River.
    - Downtown Nashua – Crown St.
        - TOD style station
    - Nashua – Spit Brook Rd.
        - Located at former Hampshire Chemical Site
        - The less contaminated portion of the site would be used as a station (park and ride style), the other half would be used as a layover facility.
        - Most of the site is an open field and could provide grasshopper sparrow habitat.
    - Nashua – Pheasant Lane Mall
        - "Park and ride" style station.
        - Additional parking at the mall would need to be provided.
- Recommendations from NH F&G and NHB:

- Existing perennial stream culverts should be updated to comply with the NH Department of Environmental Services stream crossing rules to allow for fish & wildlife passage.
- More details on the existing rail line, proposed improvements, and vegetation clearing will be needed from NH F&G and NHB to provide comments. The following species may be of particular concern:
    - Bald eagle – Nesting and roosting sites are located along Merrimack River. NH F&G mentioned that there could be mortality issues with bald eagles and faster train speeds. Other impacts could result from vegetation clearing along the Merrimack River.
    - Peregrine falcon – Chris Martin at NH Audubon should be contacted to obtain more information on primary foraging areas used by the falcons that nest in the Brady-Sullivan building in downtown Manchester.
    - Eastern hognose snake – Expansion of the rail corridor in Bow could have impacts. Field surveys would likely be required.
    - New England cottontail – Field surveys in key locations along the rail corridor would likely be needed.
    - Grasshopper sparrow – A spring field survey at the former Hampshire Chemical site in Nashua is recommended.
    - Several rare plant species and exemplary natural communities are located along the rail corridor. Field surveys to determine the extent of these species/communities are recommended by NHB.

Capitol Corridor Rail and Transit Study

Meeting with Massachusetts Natural Heritage and Endangered Species Program
August 13, 2014, 3:00 pm – 4:00 pm

Attendees:
David Paulson, Massachusetts Natural Heritage and Endangered Species Program
Carl Chamberlin, URS
Jenn Riordan, The Smart Associates

Notes:

- Carl Chamberlin provided an overview of the project, which involves the analysis of various transit investments between Boston, MA and Concord, NH. The investments could include expanded bus service and/or new commuter rail service.
- Although expanded bus service is also being considered under this project, most of the impacts to natural resources would result from the rail improvements, particularly the construction of new station and layover facilities.
- David Paulson said that the project had been previously reviewed by the Massachusetts Natural Heritage and Endangered Species Program (NHESP). The file tracking number is 01-8857.
- David said that there are three species of concern within the project corridor in Massachusetts and all occur along the Merrimack River. These species are:
    - Bald eagle.
    - Riverine clubtail (dragonfly)
    - Cobra clubtail (dragonfly)
- Bald eagles forage along the Merrimack River in the project corridor. If possible, large trees in the project corridor should be retained.
- For both the riverine clubtail and the cobra clubtail, conversion of vegetation/loss of vegetation structure and water quality impacts would be the main concerns.
- Carl explained that the existing rail lines will be replaced in Lowell. A second track will be added for a portion of Lowell and Chelmsford. The existing rail line originally had double-track to Concord. One track now remains and the second track was left as an access road. In general, vegetation removal along the tracks will be limited since the corridor is already maintained.
- Some bridges will need to be replaced. David stated that if bank stabilization is proposed, NHESP would need to know how much is proposed and may require softer stabilization techniques or specific vegetation.
- Proposed stations in Massachusetts:
    - A station may be located in Chelmsford.
    - A station is proposed at the Pheasant Lane Mall on the MA/NH border. Two options are being evaluated:
        - Option 1 – includes structured parking in the existing mall parking lot.
        - Option 2 – includes parking south of the mall.
        - Option 1 would result in less impervious surface since it is within an existing paved area. This option would be preferred by NHESP.

- David suggested providing a draft version of the MESA application to NHESP prior to filing.
- Carl explained that a Tier 1 Environmental Assessment (EA) is currently being prepared for the project. It is anticipated that this EA will be available to the public in November. NHESP could review and provide comments on the project at that time.
- David suggested looking at the online factsheets if more information on the three listed species is needed for the EA.

APPENDIX E

New Hampshire Capitol Corridor Rail and Transit Alternatives Analysis – Sustainable Land Use Report

Appendix E
Sustainable Land Use Technical Report

Table 4.4: Evaluation of Economic Goals by Alternative and Station 12
Table 5.1: Summary of Goals by Alternative 13

1 Introduction

1.1 Purpose of Report

This Sustainable Land Use Technical Report was prepared in support of Task 7 of the New Hampshire Capitol Corridor Rail & Transit Alternative Analysis (AA) Study. The objective of this report is to evaluate the sustainability of the potential land use impacts of the project in the Study corridor.

1.2 Methodology

The approach for preparing this report included the following tasks:

- Defining the scope of analysis
- Reviewing station locations for the seven intermediate alternatives
- Reviewing station area land use and economic development characteristics
- Evaluating final alternatives against the defined goals

2 Sustainable Land Use Goals

As stated in the Purpose and Need document (Appendix 2 to the Capitol Corridor AA Final Report), a sustainable transportation system is one that meets and balances the existing environmental, social, and economic needs of a community without compromising resources for future generations. Each transit investment alternative was evaluated for its ability to meet land use goals in these three categories.

- Environmental Goals:
    - Catalyze more compact, infill transit-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power) to support new development, and supporting maintenance of existing open/rural space
    - Reduce reliance on cars for trips/errands
- Social Goals:
    - Expand mobility and transportation choice for all ages
    - Support low-income households through increased access to jobs
- Economic Goals:
    - Attract employers to New Hampshire
    - Attract and retain regional employers to New Hampshire and Boston
    - Provide improved residency location choice in New Hampshire for commuters to Boston or regional jobs

2.1 Environmental Goals

The following situations describe the degree to which the transit investment may meet the defined environmental goals.

Sub goal 1: Catalyze more compact, infill transit-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power) to support new development, and supporting maintenance of existing open/rural space.

Transit investments have shown ability to catalyze or influence a Transit-Supportive Development (TSD) or Transit-Oriented Development (TOD) around station areas. Four pre-conditions are necessary for this to occur:

- Favorable real estate market conditions
- Available land for development
- Transit-supportive land use policies and plans (comprehensive plans, neighborhood plans, zoning ordinances, parking policy, etc.)
- Urban design that supports efficient and pleasant station access

These four conditions are generally mode/service-neutral. Variations in the ability to support this sub goal come from the differing degrees to which various modes and service schedules influence TSD/TOD. Fixed guideway modes (heavy rail, light rail, commuter rail, and streetcar) historically have tended to have more significant impact on development than flexible modes (express bus, standard bus, vanpool, bikeshare, etc.). Service that is more frequent and faster also tends to have a more significant impact than service that is infrequent (e.g., peak hour only, or long head-ways) or offers slower trips (e.g., all-stops vs. express or skip-stop).

By concentrating more development in existing areas (infill) around stations, not in outlying greenfield areas, transit service can reduce the need for additional infrastructure investments at the urban edge.

Likewise, as increased choice in places to live, work, and visit become available through the development of TSD/TOD, demand for development at the urban fringe that can consume agricultural land and place pressure on previously undeveloped open spaces may be reduced. The conveniences of locating closer to transit stations may come to outweigh the benefits of edge/semi-rural living for some households or businesses, increasing demand for space in existing urban areas or new infill development.

Therefore, the following can be concluded:

- Rail alternatives will meet this goal better than bus alternatives
- Alternatives with more runs/trips will meet this goal better than alternatives with fewer trips

Sub goal 2: Reduce reliance on cars for trips/errands.

Increased transit service indicates increased choice in how people travel for work, shopping, entertainment/recreation, and other purposes. Some households may choose to use transit for their trips instead of cars, which may reduce Vehicle Miles Travelled (VMT) by single-occupancy vehicles. Overall reductions in VMT reduce roadway congestion and emissions produced by passenger automobiles. The degree to which overall mode share shifts between single-occupancy passenger automobile based trips and transit, and changes in the absolute numbers of vehicle-based trips is complex and depends upon a number of circumstances:

- Travel patterns for various types of trips: local vs. regional, single-destination vs. chained trips, work vs. non-work
- Service frequency
- Station location and proximity to desired destinations
- Population and employment growth in station areas and across the service area
- Other exogenous factors, such as fuel costs

Mode-shift and VMT changes and related emissions reductions were not modeled for this Study. However, the following can be concluded:

- Alternatives that offer additional runs or trips will support this goal, with alternatives offering more frequent service coverage meeting the goal comparatively better
- Alternatives that introduce new station locations or transit access points will also meet this goal comparatively better than alternatives that use the same alignment and station locations as existing conditions

2.2 Social Goals

The following situations describe the degree to which the transit investment may meet the defined social goals.

Sub goal 1: Expand mobility and transportation choice for all ages.

Compared to the existing transit service, alternatives that introduce more opportunities for people to move efficiently from place-to-place increase mobility. This can result from increased options for routes, increased windows for travel time, and new modes or means for travel (transportation choice). Therefore, the following can be concluded:

- Alternatives that offer additional runs or trips will support this goal, with alternatives offering more frequent service coverage meeting the goal comparatively better
- Alternatives that introduce new station locations or transit access points (as destinations and as intermediate stops) will also meet this goal comparatively better than alternatives that use the same alignment and station locations as the baseline

Sub goal 2: Support low-income households through increased access to jobs.

Alternatives that introduce new connections – origins and/or destinations – or make it easier to get from place-to-place increase access. Connections to employment centers will result in increased access to jobs. Therefore, the following can be concluded:

- Alternatives that introduce new station locations or transit access points (as destinations and as intermediate stops) will meet the "increased access to jobs" component of this goal comparatively better than alternatives that use the existing alignments/routes and station locations as the baseline (assuming that one or more of the station locations [new or existing] feature employment uses within walking or connecting distance of the station)
- New station/stop locations that are located within areas that have a presence of low-income households, or that have connections (via feeder bus, pedestrian or non-motorized paths, or roadways) to areas with a presence of low-income households will meet the "supports low-income households" component of this goal comparatively better than alternatives that feature station locations in areas where household incomes meet or exceed area median incomes

2.3 Economic Goals

The following situations describe the degree to which the transit investment may meet the defined economic goals. As discussed in the *Social Goals* section above, alternatives that create more opportunities for people to move efficiently from place-to-place and open up more connections to transportation serve to increase access and mobility. Access and mobility also affect the economies of the places served by transportation, at local and regional levels.

Sub goal 1: Attract employers locally to New Hampshire, and attract and retain regional employers from New Hampshire to Boston.

Employers in most industry sectors consider a variety of labor force characteristics when choosing locations for their business concerns. These may include typical levels of educational attainment and availability of specialized skills required by their business processes, but also consider to some degree how easy it will be for employees to get to work or to conduct any intra-workday travel that may be required. Good access and high degrees of resident mobility correspond to workforce stability, on-time performance, and lower levels of turnover related directly to employees' ability to get to work consistently and on time.

From the perspective of current or prospective employees, the transportation infrastructure that provides access to a job site also affects the decision to take a job with that company, whether the employer contributes financially to its construction and operation or not. Other factors being equal, employees may choose a job that is easier to get to, or for which they have multiple choices in how to get to, over another similar job that is less accessible. In this way, employers may also present transportation access as a job benefit and way to attract and retain quality employees.

Therefore, the following can be concluded:

- Alternatives that offer increased access and mobility will support this goal, with alternatives offering more frequent service and/or new station locations or transit access points meeting this goal comparatively better than alternatives that use the same alignment and station locations as the baseline
- Alternatives that provide more reliable service (i.e., rail-based or in dedicated right-of-way) will meet this goal comparatively better than alternatives that simply provide more service

Sub goal 2: Provide improved residency location choice in New Hampshire for commuters to Boston or regional jobs.

For many households, the decision on where to live may include preferences for a certain style or price-point of housing stock, neighborhood, or community, and proximity to shopping, healthcare, and open and space/recreation (among other types of destinations). Other factors may include proximity to extended family, or ties to an area where household members grew up or previously lived. For many, access to employment is also important: choice and convenience in ways to get to work, travel time length and consistency, and impacts of the commute on quality-of-life. Transportation investments that increase access across a region and increase the number of potential connections between residential centers and employment centers provide more choice to employees as to where they can live according to their preferences (e.g., a rural New Hampshire hamlet with a short drive to a transit station) and still work in the region (e.g., Boston's financial district).

Multiple choices will help retain skilled employees and productive citizens in the region, because they are not obligated to move away from their preferred residence location to access jobs. Communities may have an additional desire to maintain the balanced age distribution necessary for healthy communities, and retaining workers in all age groups accomplishes that policy goal. (For example, young professional workers from New Hampshire who work in Boston are less likely to move to Massachusetts to work in their industry of choice.)

Therefore, the following can be concluded:

- Alternatives that offer increased access will support this goal, with alternatives offering more new station locations or transit access points meeting this goal comparatively better than alternatives that use the same alignment and station locations as the baseline

3 Review of Station Characteristics

3.1 Summary of Final Alternatives

This section describes the baseline, three bus, two commuter rail, and one intercity rail investment options that advanced through preliminary screening leading towards the selection of recommended strategies (see Tables 3.1 and 3.2). Details concerning each final investment option are listed below with more detail available in the Task 7 Technical Report, Detailed Evaluation of Final Alternatives (Appendix 7 to the AA Final Report).

Table 3.1: Summary of Alternatives

Base	▪ No investment; existing bus and rail services are continued, but not expanded
Expanded Base	▪ New Hampshire's Boston Express (BX) bus service is increased from current 80 buses per day to 120 buses per day ▪ All peak buses run direct and non-stop between each NH park-and-ride lot and Boston South Station with service every 30 minutes ▪ Each park-and-ride lot sees hourly off-peak service making intermediate stops at each NH park-and-ride lot ▪ No changes to existing passenger rail services
Bus on Shoulder	▪ BX bus service of 80 daily trips is permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes ▪ Savings of eight to 12 minutes predicted during the morning peak period ▪ No significant travel time savings predicted during the afternoon peak period
Expanded Bus on Shoulder	▪ 120 daily trips permitted to operate within the I-93 shoulder south of I-495 to bypass congestion in general travel lanes ▪ Savings of eight to 12 minutes predicted during the morning peak period ▪ No significant travel time savings predicted during the afternoon peak period
Manchester Regional Commuter Rail	▪ Extends Massachusetts Bay Transportation Authority (MBTA) commuter rail service north from Lowell, MA to Manchester, NH with intermediate stops at South Nashua, Nashua Crown St., and Bedford/Manchester-Boston Regional Airport (Bedford/MHT) ▪ BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained ▪ BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained
Nashua Minimum Commuter Rail	▪ Extends MBTA commuter service north from Lowell, MA to South Nashua, NH ▪ BX I-93 service to Manchester, North Londonderry, Londonderry, and Salem is retained ▪ BX Route 3 service to Manchester, Nashua, and Tyngsborough is retained
Intercity 8	▪ Four daily intercity passenger rail round trips between Concord, NH and Boston, MA making intermediate stops at Manchester, Bedford/MHT, Nashua Crown St., and Lowell and Woburn, MA ▪ Base BX service is retained

Table 3.2: Stations Served by Alternatives

Location	Rail Station (Proposed)	Bus Station (Existing)	Stations Served by Alternative						
			Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8
Number of Stations (excluding existing MA + Boston terminal)			7 Bus	7 Bus	7 Bus	7 Bus	4 Rail 5 Bus	1 Rail 4 Bus	4 Rail 8 Bus
Concord, NH	X	X	B	B	B	B	B	-	R, B
Manchester, NH: Granite Street	X	X	B	B	B	B	R, B	B	R, B
Bedford/MHT	X		-	-	-	-	R	-	R
N. Londonderry, NH: Exit 5		X	B	B	B	B	B	B	B
Londonderry, NH: Exit 4		X	B	B	B	B	B	B	B
Nashua, NH: Exit 8		X	B	B	B	B	-	-	B

Tyngsborough, MA: Exit 36		X	B	B	B	B	-	-	B
Salem, NH: Exit 2		X	B	B	B	B	B	B	B

3.2 Summary of Land Use and Economic Development Conditions

A detailed analysis of the land use and economic development characteristics of proposed transit stations is contained in the technical memorandum *Land Use & Economic Development Analysis* dated January 2014 and in the draft supporting working memorandum *Land Use Evaluation of Alternatives for Preliminary Screening* dated September 2013. The findings from those memoranda are not repeated here, but are incorporated by reference.

4 Analysis Presented by Goal

This section of the report contains a qualitative assessment of each alternative's anticipated potential to meet the three sustainable land use goals. This qualitative assessment is based upon an understanding of service levels and route characteristics of the alternatives, as well as the varied land use and socio-economic characteristics of each of the station areas served by the alternative.

A station-level assessment is provided for each station area served by an alternative, with footnotes explaining the rationale for assessment. Assessments were absolute, not relative rankings among alternatives. Ratings are provided on the following scale:

- N/A: For the alternative, there is no service to this station
- No Change: This alternative is not anticipated to have any effect on this aspect of sustainable land use
- Negative: This alternative could potentially reduce sustainability
- Low: This alternative is anticipated to have some positive effect on this aspect of sustainable land use
- Medium: This alternative is anticipated to have a solidly positive effect on this aspect of sustainable land use
- High: This alternative is anticipated to have a very positive effect on this aspect of sustainable land use

These very localized assessments were then rolled-up as a composite assessment for the overall alternative. A summary of the composite goals is presented in Section 5.0.

4.1 Environmental Goals

Environmental Goals:

1. Catalyze more compact, infill transit-supportive land use and development patterns, thereby reducing the need for additional infrastructure (sewer, water, power) to support new development, and supporting maintenance of existing open/rural space
2. Reduce reliance on cars for trips/errands

Assessments for the Environmental Goals are presented in Tables 4.1 and 4.2. Each sub-goal was assessed separately due to different influencing factors.

Table 4.1: Evaluation of Environmental Goals by Alternative and Station

Location	Rail Station (Proposed)	Bus Station (Existing)	Alternative						
			Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8

[1] Traditional bus service was not correlated to changing or encouraging more transit-oriented land use and development patterns, particularly in systems with highway service and park-and-ride commuter stations

[2] Bus on shoulder was not correlated to changing or encouraging more transit-oriented land use and development patterns, particularly in systems with highway service and park-and-ride commuter stations

[3] Proposed station location, local real estate conditions, accessibility and urban design, and service schedule suggest some positive potential for transit-oriented development

[4] Proposed station location, local real estate conditions, accessibility and urban design, and service schedule suggest positive potential for TOD

[5] Elimination of bus service may reduce or eliminate the marginal correlations of bus service to TOD patterns

[6] Proposed station location, local real estate conditions, accessibility and urban design, function as a park-and-ride, and service schedule suggest little potential for TOD

Table 4.2: Evaluation of Environmental Goals by Alternative and Station

[7] *Increased service may provide more choice for use in some trips, but only between stations, as this is commuter service, not local service*
[8] *Increased travel speed may provide more choice for use in some trips, but only between stations, as this is commuter service, not local service*
[9] *Elimination of bus service may reduce or eliminate choice for some trips*

4.2 Social Goals

Social Goals:

- Expand mobility and transportation choice for all ages
- Support low-income households through increased access to jobs

Assessments for the Social Goals are presented in Tables 4.3. The two sub-goals have been assessed together due to the same influencing factors.

Table 4.3: Evaluation of Social Goals by Alternative and Station

Location	Rail Station (Proposed)	Bus Station (Existing)	Stations Served by Alternative						
			Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8

Tyngsborough, MA: Exit 36		X	no change	low [10]	low [10]	low [10]	n/a	n/a	n/a
Salem, NH: Exit 2		X	no change	low [10]	low [10]	low [10]	low/no change [10]	low/no change [10]	no change [10]

[10] *Increased service or new station will provide more choice for use in some trips, increasing access and mobility*
[11] *Elimination of bus service may reduce or eliminate choice for some trips, reducing access and mobility*

4.3 Economic Goals

Economic Goals:

- Attract employers locally to New Hampshire
- Attract and retains regional employers from New Hampshire to Boston
- Provide improved residency location choice in New Hampshire for commuters to Boston or regional jobs

Assessments for the Economic Goals are presented in Tables 4.4. The three sub-goals have been assessed together due to the same influencing factors.

Table 4.4: Evaluation of Economic Goals by Alternative and Station

Location	Rail Station (Proposed)	Bus Station (Existing)	Stations served by Alternative						
			Base	Expanded Base	Bus on Shoulder	Expanded Bus on Shoulder	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail	Intercity 8

Nashua, NH: Exit 8		X	no change	medium [13]	low [13]	medium [13]	no change/ negative [13,14]	no change/ negative [13,14]	low/no change [13]
Nashua, NH: Crown Street	X		n/a	n/a	n/a	n/a	medium [12]	n/a	medium [12]
South Nashua, NH: Spit Brook Road or Pheasant Lane Mall	X		n/a	n/a	n/a	n/a	medium [12]	medium [12]	n/a
Tyngsborough, MA: Exit 36		X	no change	medium [13]	low [13]	medium [13]	n/a	n/a	n/a
Salem, NH: Exit 2		X	no change	medium [13]	low [13]	medium [13]	low/no change [13]	low/no change [13]	low/no change [13]

[12] *New stations provide more options for local residents to commute within alignment or to Massachusetts/Boston destinations, expanding worker market*
[13] *Increased service or more reliable service can be perceived as employment market asset*
[14] *Elimination of some bus service may reduce or eliminate access for some workers to commuting options*

5 Summary of Analysis

5.1 Summary Assessment of Goals by Alternative

Table 5.1 presents the composite assessments for each of the three categories of sustainable land use goals by alternative. The summary assessment is a roll-up of the composite assessments.

Table 5.1: Summary of Goals by Alternative

	Alternative						
	Base	**Expanded Base**	**Bus on Shoulder**	**Expanded Bus on Shoulder**	**Manchester Regional Commuter Rail**	**Nashua Regional Commuter Rail**	**Intercity 8**
Environmental Goals	no change	low	low	low	medium	low	low/ medium
Social Goals	no change	low	low	low	low/mediu m	low	low/ medium
Economic Goals	no change	medium	low	medium	medium	low	medium
Summary Assessment	**no change**	**low**	**low**	**low/ medium**	**medium**	**low**	**medium**

In summary, the three rail alternatives have higher qualitative assessments of contributing to sustainable land use than the bus alternatives or base scenario. As described in Section 2.0, rail investments have typically been perceived by the public (riders and community stakeholders) as more permanent and as providing greater levels-of-service and benefit than bus enhancements.

1 Introduction

Equitable access to transit investments – and the mobility benefits that these investments confer on riders – is an important consideration when assessing the alternatives developed through the Capitol Corridor Alternative Analysis (AA). Public transit investment supports broad improvements in mobility, but is a particularly critical tool in increasing the mobility of transit-reliant or -dependent populations, including households below the poverty line, minorities, and households in affordable housing units.

U.S. Census data was used to calculate statistics related to income, race, and housing for households and individuals in Census tracts within a half-mile of the Capitol Corridor alternatives (Pan Am Railways [PAR] right-of-way between the state lines of New Hampshire and Massachusetts and the potential rail station location in Concord, New Hampshire; Boston Express (BX) bus route between the state lines of New Hampshire and Massachusetts and the existing Manchester, New Hampshire BX station; and the Concord Coach bus route between the state lines of New Hampshire and Massachusetts and the existing Concord, New Hampshire Concord Coach station).

This data was also collected for the States of New Hampshire and Massachusetts, and the U.S. comparison between the alternatives within the larger geographic context will support the analysis of which alternatives minimize potential adverse impacts on concentrations of households below the poverty line, minority populations, and households in affordable housing units, while supporting equitable transit access by these populations.

2 Income and Poverty

Income is an important element of the equity analysis because the costs associated with car ownership are relatively fixed, and can consume a comparatively larger percentage of lower-income household budgets. Access to transit allows households to maintain mobility and access while reducing the household expenditures on transportation, which then increases the amount of discretionary budget available to the household.

Table 2.1 shows the median income of households in Census tracts within a half-mile of the Capitol Corridor alternatives, the States of New Hampshire and Massachusetts, and the U.S., as well as the percent of the population within a half-mile of the Capitol Corridor alternatives whose household income falls below the federal poverty line.

Table 2.1: Median Households Income and Percent of Population below the Poverty Line

	Median Household Income				% Below Poverty Line		
	2000	2000$ Adjusted for 2011	2011	% Change Adjusted for 2011 $	2000	2011	% Change
Capitol Corridor	--	--	$64,754	--	--	9.0%	--
New Hampshire	$49,467	$64,617	$64,664	0%	6.5%	8.0%	23%
Massachusetts	$50,502	$65,969	$65,981	0%	9.3%	10.7%	15%
U.S.	$41,994	$54,855	$52,762	-4%	12.4%	14.3%	15%

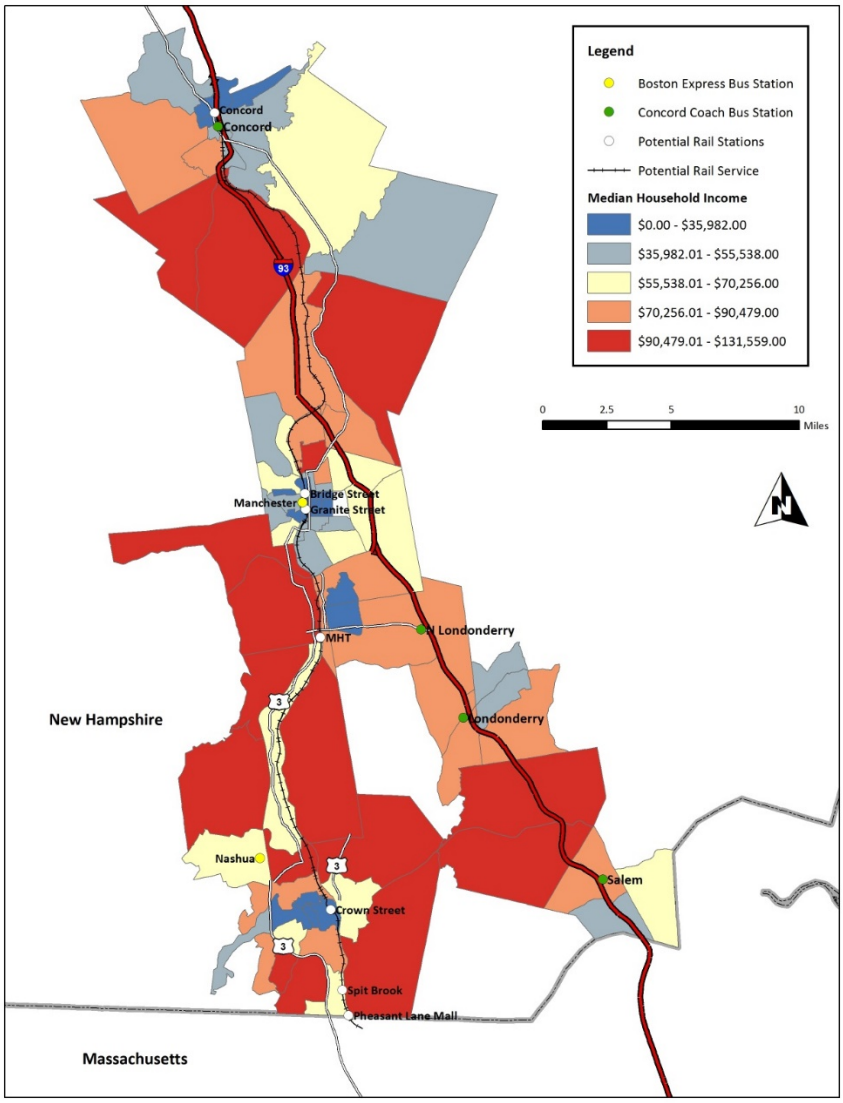
Source: U.S. Census 2000, ACS 2007-2011

The 2011 median household income of the Census tracts within a half-mile of the Capitol Corridor alternatives is approximately the same as the median household income for the State of New Hampshire. The 2011 percentage of the population below the poverty line is also lower in the Capitol Corridor than in Massachusetts or the U.S.

2.1 Median Household Income

While median household income within the Capitol Corridor is comparatively high, median household income declines in the urban areas, closer to where the potential rail stations would be located. Figure 2.1 shows Census tracts within a half-mile of all Capitol Corridor alternatives.

Figure 2.1: Median Income in Capitol Corridor by Census Tract



The median income in the cities of Concord, Manchester, and Nashua are all lower than the areas immediately surrounding each of these cities. Alternatives that have central-city station locations would expand the mobility options of the comparatively lower-income households that are concentrated in the urban areas. Service and operational improvements made to the BX service as part of the bus-based Capitol Corridor alternatives are unlikely to adversely impact comparatively lower-income households within the corridor; however, these alternatives are also unlikely to improve access to transit by this population because they will not result in the construction of new stations (and improved transit access) in areas with comparatively lower-income households.

2.2 Poverty

The percent of Capitol Corridor population living below the poverty line is consistent with or lower than state or national rates (Table 2.2).

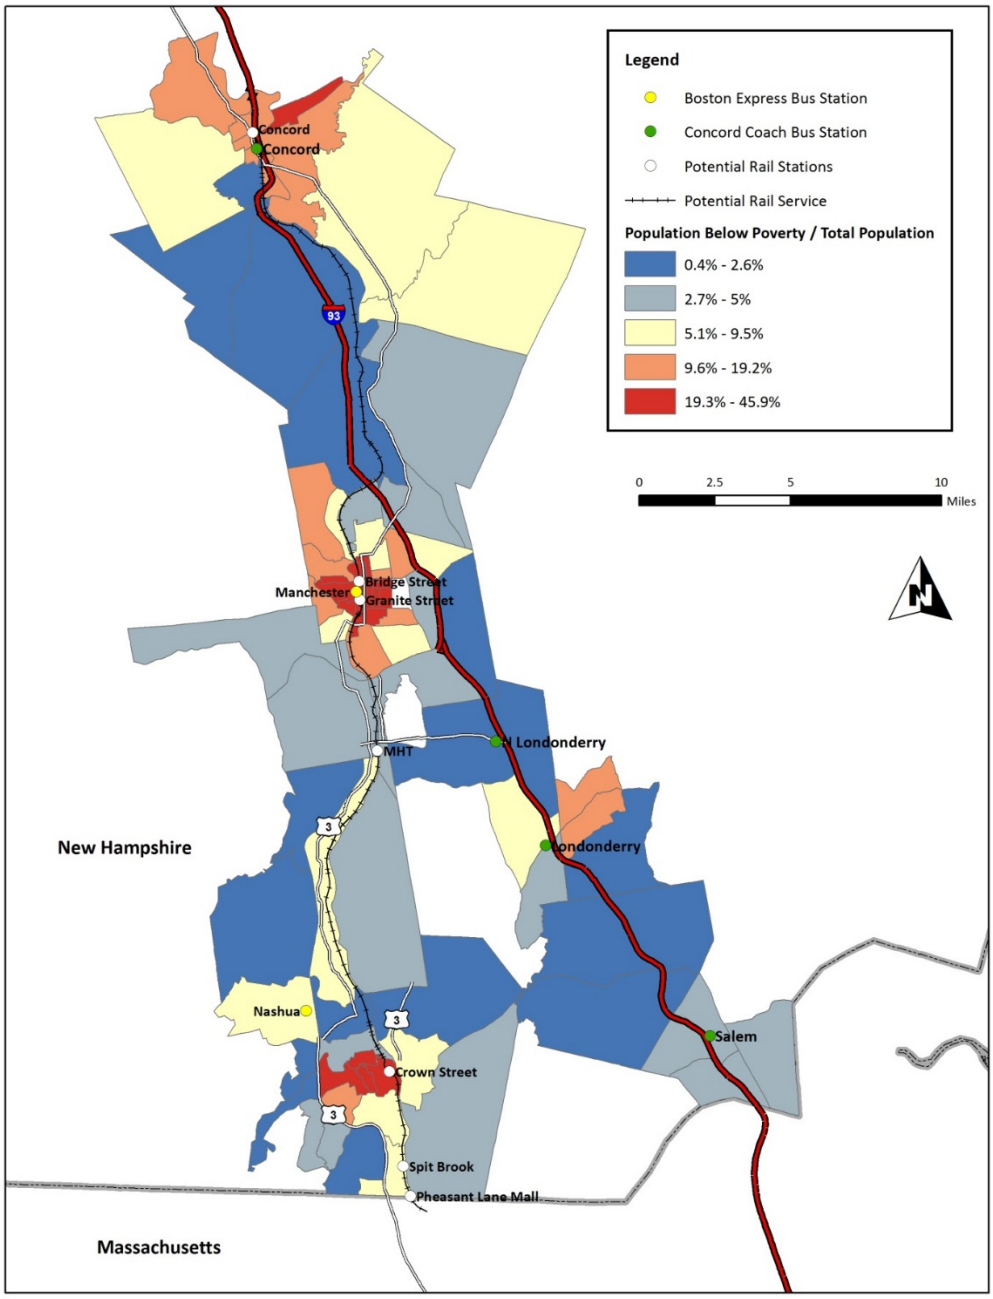
Table 2.2: Percent of Population Living below the Poverty Line

Geography	% Below Poverty Line
Capitol Corridor	9%
New Hampshire	8%
Massachusetts	11%
U.S.	14%

Source: U.S. Census, ACS 2008-2012

However, the poverty levels are comparatively higher in the central areas of Concord, Manchester, and Nashua. As Figure 2.2 shows, the poverty level in those downtowns ranges from 19 to 46 percent. Transit investments that directly serve these urban households living below the poverty line would promote equity through increased access to comparatively lower-cost transportation options. Service and operational improvements made to the BX service as part of the bus-based Capitol Corridor alternatives are unlikely to adversely impact people living below the poverty line within the corridor; however, these alternatives are also unlikely to improve access to transit by this population because they will not result in the construction of new stations (and improved transit access) in areas with comparatively large shares of the population living below the poverty line.

Figure 2.2: Percent of Population Living Below the Poverty Line



3 Minority Population

Approximately 10 percent of the population in Census tracts within a half-mile of the Capitol Corridor alternatives is non-white. Though this is higher than the minority population found within the State of New Hampshire (six percent), it is substantially lower than the percent of minority population found in the State of Massachusetts (19 percent) and the U.S. (26 percent), as shown in Table 3.1.

Table 3.1: Minority Population

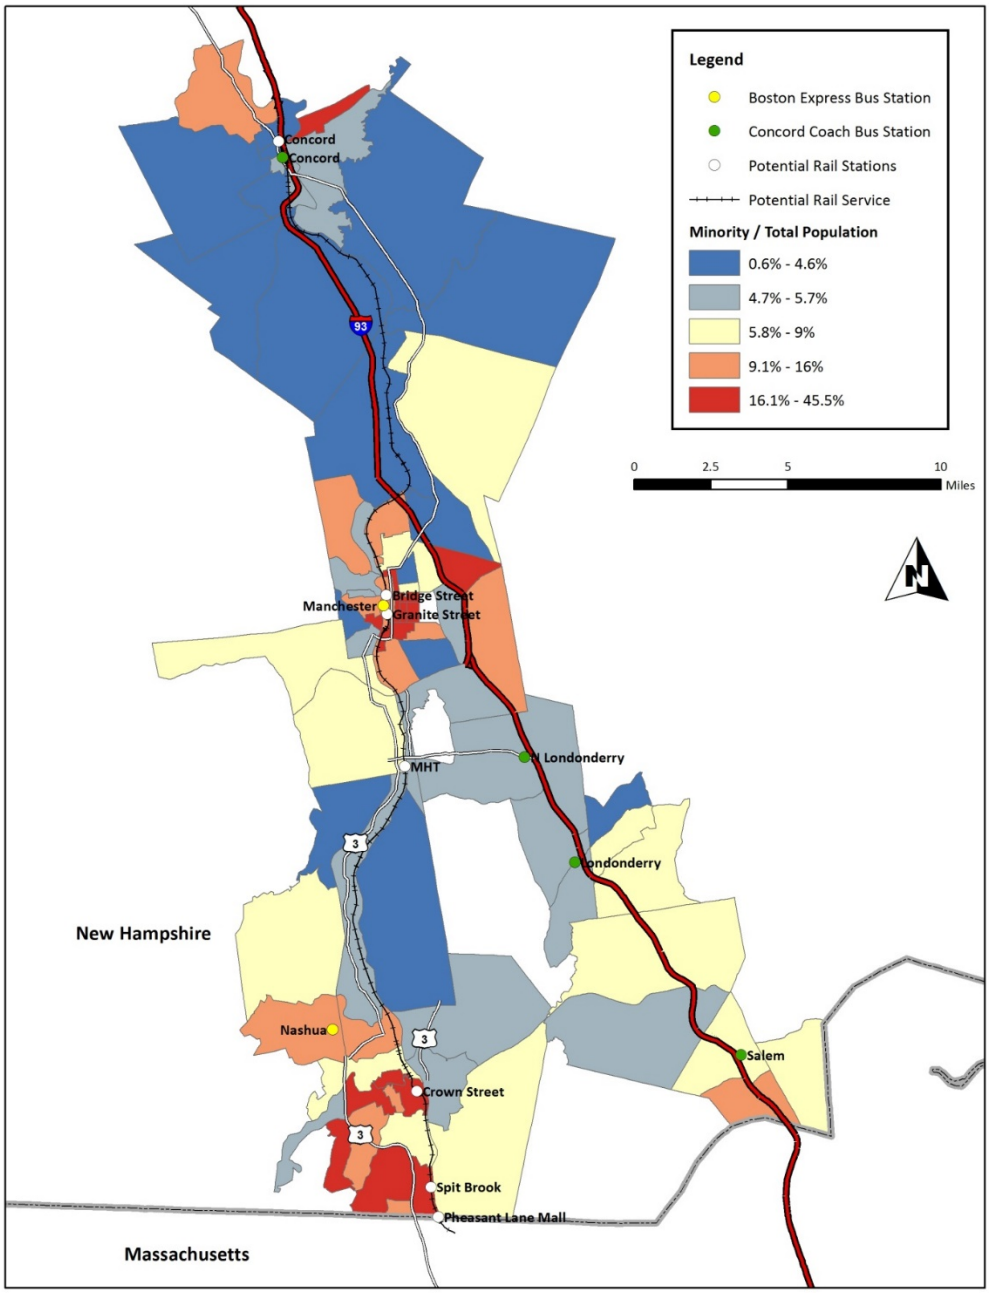
Geography	% Minority
Capitol Corridor	10%
New Hampshire	6%
Massachusetts	19%
U.S.	26%

Source: U.S. Census, ACS 2008-2012.

While the data shows that the share of minority population within the Capitol Corridor is comparatively lower than is found throughout Massachusetts and across the U.S., minority share of the population is comparatively higher in the central areas of Concord, Manchester, and Nashua. The minority population share in some parts of these cities reaches 45 percent. Figure 3.1 illustrates shares of minority population within the Capitol Corridor.

Alternatives that serve the downtown core of Concord, Manchester, and Nashua will serve the greatest shares of minority populations within the Capitol Corridor. Service and operational improvements made to the BX service as part of the bus-based Capitol Corridor alternatives are unlikely to adversely impact minority populations within the corridor; however, these alternatives are also unlikely to improve access to transit by this population because they will not result in the construction of new stations (and improved transit access) in areas with comparatively large shares of minority populations.

Figure 3.1: Minority Share of the Population



4 Affordable Housing

Many cities and states choose to develop voluntary or mandatory affordable housing statutes as a means to maintain an economically-diverse population and support diversity of housing choice.

New Hampshire has a Workforce Housing Law that went into effect on January 1, 2010. This law codifies and clarifies the 1991 New Hampshire Supreme Court decision in *Britton v. Town of Chester*, and requires all municipalities to provide reasonable and realistic opportunities for the development of workforce housing. It does not require that municipalities set aside a set percentage of its housing stock as affordable.

Here are some highlights of New Hampshire's Workforce Housing law:

- In every municipality that exercises the power to adopt land use ordinances and regulations, such ordinances and regulations must provide reasonable and realistic opportunities for the development of workforce housing, including rental multi-family housing. To provide such opportunities, lot size and overall density requirements for workforce housing must be reasonable. A municipality that adopts land use ordinances and regulations must allow workforce housing to be located in a majority, but not necessarily all, of the land area that is zoned to permit residential uses within the municipality.
- "Workforce housing" means housing that is intended for sale and that is affordable to a household with an income of no more than 100 percent of the median income for a four-person household for the metropolitan area or county in which the housing is located.
- "Workforce housing" also means rental housing that is affordable to a household with an income of no more than 60 percent of the median income for a three-person household for the metropolitan area or county in which the housing is located.
- Housing developments that exclude minor children from more than 20 percent of the units or in which more than 50 percent of the dwelling units have fewer than two bedrooms must not constitute workforce housing.

Concord, Manchester, and Nashua each have several affordable housing developments within a half-mile radius of the potential rail station locations. While the income of the households targeted for residence in these affordable housing units may not fall below the federal poverty line (as discussed in Section 2.0), additional comparatively lower-cost alternatives to car ownership (such as access to transit) can help to reduce the share of household income spent on transportation costs. Service and operational improvements made to the BX service as part of the bus-based Capitol Corridor alternatives are unlikely to adversely impact existing or planned affordable housing units; however, these alternatives are also unlikely to improve access to transit by this population because they will not result in the construction of new stations (and improved transit access) in areas with concentrations of affordable housing.

4.1 Concord

There are 11 affordable housing sites within a half-mile of the potential Concord rail station. Within the 11 sites, there are 398 affordable housing units (Figure 4.1 and Table 4.1).

Figure 4.1: Affordable Housing Sites in Concord

Table 4.1: Concord Affordable Housing Developments

John F Kennedy	86	1820 House	4
		Mennino Place	45
		Total Units	**398**

4.2 Manchester

There are 17 affordable housing sites within a half-mile radius of the proposed Granite Street Manchester rail stations. There are a total of 675 affordable housing units within these 17 sites (Figure 4.2 and Table 4.2).

Figure 4.2: Affordable Housing Sites in Manchester

5 Conclusion

The three populations considered as part of this equity analysis – population below the poverty line, minority populations, and households living in affordable housing units – tend to be concentrated in the central areas of Concord, Manchester, and Nashua. When compared to the base and bus alternatives, the rail alternatives offer comparatively higher levels of service and transit access to these populations with minimal adverse impacts anticipated. The equity of and access to the rail alternatives improves as transit service extends north from Nashua (to Manchester and/or Concord) because those alternatives (Manchester Regional Commuter Rail and Intercity 8), reach more individuals and households living below the poverty line, minority households, and households living in affordable housing units. The base and all bus alternatives would not adversely impact these populations either, but also would not offer expanded access to these populations through new station locations. Table 5.1 provides a summary of the equity metrics for each of the existing bus stations and proposed rail stations.

Table 5.1: Summary of Alternatives

Station Area (Half-Mile Buffer)	Proposed Rail Station	Existing Bus Station	Equity Metrics				Stations Served by Alternative(s)			
			Average Median Income	Population Below Poverty	Minority Population	Affordable Housing Units	Base and all Bus Alternatives	Intercity 8	Manchester Regional Commuter Rail	Nashua Minimum Commuter Rail
Concord, NH	X	X	$39,000	18.0%	9.7%	398	X	X		
Manchester, NH	X	X	$30,300	29.5%	26.1%	675	X	X	X

RE: Project Notification Form
New Hampshire Capitol Corridor Rail and Transit Study
Lowell, Tyngsborough, and Chelmsford, Middlesex County, MA

Dear Ms. Simon:

Enclosed, please find a Project Notification Form and support documentation for the proposed New Hampshire Capitol Corridor Rail and Transit Study (the Project). The New Hampshire Department of Transportation (NHDOT) is working with the Massachusetts Department of Transportation (MDOT) to evaluate a diverse set of rail and bus options for improving connectivity and passenger service between the major population centers of New Hampshire and metropolitan Boston. The project is evaluating opportunities to improve inter-city transit service in the 73-mile corridor by leveraging existing transportation infrastructure, including the Pan Am Railway, US Route 3, and I-93. The Project will evaluate approximately 10-miles of existing railroad in Massachusetts that passes through Lowell, Tyngsborough, and Chelmsford in Middlesex County, paralleling the Merrimack River the majority of the route.

It is anticipated that the Project will receive funds from the Federal Transportation Administration (FTA) and the Federal Railroad Administration (FRA). Federal licenses, permits, or approvals may also be required as part of this project. As a federally funded/licensed project, the Project is subject to review under Section 106 of the National Historic Preservation Act of 1966, as amended (36 CFR Part 800). To satisfy requirements under Section 106, URS has prepared and attached a Phase IA Cultural Resources Investigation for your review.

If you have questions, please do not hesitate to contact me at 609-386-5444 or via e-mail at joel.dworsky@urs.com .

Yours truly,

Joel G. Dworsky
Senior Archaeologist/Geospatial Analyst

PROJECT NOTIFICATION FORM

Project Name: New Hampshire Capitol Corridor Rail and Transit Study

Location / Address: (will follow the existing New Hampshire Main Line)

City / Town: Lowell, Tyngsborough, and Chelmsford - Middlesex County

Project Proponent

Name: New Hampshire Department of Transportation

Address: John O. Morton Building, 7 Hazen Drive, P.O. Box 483

City/Town/Zip/Telephone: Concord, New Hampshire 03302-0483 (603) 271-3734

Agency license or funding for the project (list all licenses, permits, approvals, grants or other entitlements being sought from state and federal agencies).

Agency Name	Type of License or funding (specify)
Federal Railroad Administration	Grant
Federal Transit administration	Grant

Project Description (narrative):

See Section 1.1 in the Phase IA Cultural Resources Investigation report

Does the project include demolition? If so, specify nature of demolition and describe the building(s) which are proposed for demolition.

No demolition is proposed.

Does the project include rehabilitation of any existing buildings? If so, specify nature of rehabilitation and describe the building(s) which are proposed for rehabilitation.

No rehabilitation is proposed.

Does the project include new construction? If so, describe (attach plans and elevations if necessary).

Proposed work will only consist of the addition of a second railroad track within the existing right-of-way. The locations are depicted in mapping included in Appendix A of the aforementioned report.

To the best of your knowledge, are any historic or archaeological properties known to exist within the project's area of potential impact? If so, specify.

See attachment

What is the total acreage of the project area?

Woodland		acres	Productive Resources:		
Wetland		acres	Agriculture		acres
Floodplain		acres	Forestry		acres
Open Space		acres	Mining/Extraction		acres
Developed	~120	acres	Total Project Acreage		acres

What is the acreage of the proposed new construction? ~120 acres

What is the present land use of the project area?

Railroad-related and industrial use.

Please attach a copy of the section of the USGS quadrangle map which clearly marks the project location.

This Project Notification Form has been submitted to the MHC in compliance with 950 CMR 71.00.

Abstract

URS Corporation (URS) conducted a Phase IA survey of the proposed construction area of potential effects (APE) for the New Hampshire Department of Transportation's Capitol Corridor Rail Transit Study. This report presents the results of a Phase IA reconnaissance of a project area spanning the existing rail corridor from Lowell, Massachusetts, to the Massachusetts-New Hampshire border. This report focuses on the section of the project area located in Massachusetts, contained within Middlesex County. The project APE for this survey effort is comprised of a 9-mile-long corridor of existing railroad bed connecting Lowell, Massachusetts, to Nashua, New Hampshire. The proposed APE was examined to establish the archaeological potential of the study corridor, as well as determine the impact of the proposed construction on extant historic structures. Vanessa Zeoli, architectural historian, examined the APE for evidence of historic structures and determined the potential effect the construction would have upon these resources. Joel Dworsky, archaeologist, conducted a Phase IA archaeological reconnaissance of a 1-kilometer buffer surrounding the APE to establish the archaeological sensitivity of the area. This effort included a review of the known prehistoric and historic sites, as well as a survey of historic maps of the region, a determination of archaeological potential was synthesized.

URS compiled determinations of archaeological sensitivity for the Lowell Study Area, the aforementioned 1-kilometer buffer surrounding the APE. Overall, the prehistoric potential for the study areas remained consistently high, owing in large part to the proximity of the construction APE to the Merrimack River. The historical archaeological sensitivity was also determined to be high, given the density of historic settlement within the study area. The archaeological sensitivity for historic archaeological resources was subdivided into site types. Analysis of these site types revealed that sites of an industrial or transportation-related association were the most likely form of historic archaeological material to be encountered. Both of these site types were frequently situated along the river and its tributaries, from which they derived operational power and transportation. As the extant rail bed follows the course of the Merrimack River, the likelihood of encountering industry/transportation-related resources is therefore high.

The historic architecture survey of the proposed construction APE consisted of an inventory of previously identified historic properties recorded within or adjacent to the proposed APE, as well as a windshield survey of the project APE. Several historic resources were identified during the survey effort.

Despite the high potential of encountering historic structures and archaeological sites in the area near the proposed APE, URS has determined that no further cultural resource survey is necessary in Massachusetts. Given that the project calls for the reestablishment of a secondary set of rails upon an existing rail bed that was historically utilized for the same purpose, as well as the knowledge that limited ground disturbance will occur during this effort, it has been determined that the proposed construction poses no adverse effects to cultural resources. However, the determination that no further archaeological work is required is contingent upon the construction effort causing no subsurface disturbance. Should construction move forward, any action that would disturb subsurface soils would either need to be monitored or archaeologically investigated via Phase IB survey, due to the high archaeological sensitivity of the area.

1.0 Introduction

The Federal Railroad Administration (FRA), acting as the lead federal agency; the Federal Transit Administration (FTA), as a cooperating agency; and the New Hampshire Department of Transportation (NHDOT), as the project sponsors, are proposing to evaluate the feasibility of developing new rail and transit services in the 73-mile corridor between Boston, Massachusetts, and Concord, New Hampshire (Figure 1). To satisfy requirements under the National Environmental Policy Act (NEPA) of 1969, as amended, NHDOT is preparing an environmental assessment (EA). The New Hampshire Capitol Corridor Rail and Transit Study (the project) is a federal undertaking and, as such, is also subject to review under Section 106 of the National Historic Preservation Act of 1966 (NHPA), as amended, and the implementing regulations, 36 CFR Part 800. To initiate consultation under Section 106 among the FRA, FTA, NHDOT, and the Massachusetts Historical Commission (MHC), URS has prepared a project notification form (PNF) and a Phase IA cultural resource reconnaissance. This investigation also serves to supplement and inform the EA, being completed as part of the NEPA process. The purpose of this Phase IA investigation is to record the presence or absence of archaeological and historic architectural resources within the area of potential effects (APE). This study is part of the initial stage of the project to evaluated existing conditions of the project area. The PNF and Phase IA investigation were all prepared in accordance with the guidelines set forth by the NHPA and the MHC.

1.1 *Project Description*

As noted above, the New Hampshire Capitol Corridor Rail and Transit Study is defining and evaluating opportunities to address transportation needs and preferences that involve transit and rail options in the 73-mile corridor between Boston, Massachusetts, and Concord, New Hampshire. While Massachusetts Bay Transportation Authority (MBTA) commuter rail service currently operates between Boston and Lowell, there has not been commuter rail passenger service north of Lowell since it was discontinued in 1967. A public-private partnership, supported by the state of New Hampshire, operates roughly 50 daily bus roundtrips within the corridor between New Hampshire and Boston; this service typically carries 1,800 passengers per day.

Increasing transportation demand and growing concerns about mobility, economic development, and quality of life have led the citizens and officials in New Hampshire and Massachusetts to explore options to improve transit service along the northern end of the Capitol Corridor. The New Hampshire Capitol Corridor Study is evaluating a diverse set of rail and bus options for improving connectivity in the Capitol Corridor by leveraging existing transportation infrastructure, including Pan Am Railway, Route 3, and I-93. The study, which will be completed in late 2014, will result in the recommendation of a preferred investment strategy that is responsive to local transportation need and the region's economic, social, financial, and environmental context—and that will be competitive for federal construction funding.

1.2 *Proposed Station and Layover Facilities*

Proposed station and layover facilities are only proposed for construction in New Hampshire; *no stations or layover facilities will be constructed in Massachusetts*. There are 10 potential station and layover alternatives being explored between Concord and Nashua, New Hampshire, during this preliminary phase. Station facilities will generally consist of 800-foot open platforms that will be constructed within the existing railroad right-of-way (ROW); 100-foot access platforms with ramps and stairs; a maintenance building; parking lots to accommodate commuters; street striping for new drop-off/pick-up traffic; grade crossings; and new tracks for platform access and turnouts. Layover facilities will generally consist of

Figure 1- Project location map (Source: United States Geological Survey 2009).

maintenance and substation buildings; additional tracks for the layover area; retaining walls; and access roads. The following is a list of station and layover facility alternatives proposed in New Hampshire.

Station Facilities (seven alternatives proposed for station facilities)

- Stickney Avenue Station in Concord
- Spring Street Station in Manchester
- Granite Street Station in Manchester
- Ray Wieczorek Drive Station in Bedford
- Crown Street Station in Nashua
- Spit Brook Station in Nashua
- Pheasant Lane Mall Station in Nashua

Layover Facilities (five alternatives proposed for layover facilities)

- Stickney Avenue Layover Facility in Concord
- Granite Street Layover Facility in Manchester
- Cemetery Layover Facility in Manchester
- Water Treatment Plant Layover Facility in Manchester
- Spit Brook Layover Facility in Nashua

In addition to the station and layover facilities, a second track will be added to certain portions of the existing ROW along the 73-mile stretch. *The addition of a second track is the only improvement proposed in Massachusetts.* See Appendix B for a map showing the locations of the new track.

1.3 *Scope of Work and Project Personnel*

The Phase IA investigation involved background research, development of archaeological sensitivity models, and a field visit/reconnaissance of the project area. The background research was initiated in order to locate previously identified archaeological or historic architectural resources within or in close proximity to the project area and review the results of previous cultural resources work within the project area and its vicinity. The archaeological sensitivity models were developed to assess the potential (i.e., high, medium, or low) for archaeological resources within the project area. URS initiated the field visit/reconnaissance in order to ground-truth the initial research and identify any unrecorded archaeological or historic architectural resources.

The purpose of this study is not to definitively identify and document every cultural resource in the APE; rather, it only inventories any previously documented historic properties listed in or eligible for listing in the State Register of Historic Places (SRHP) and/or the National Register of Historic Places (NRHP), and indicates the likelihood that previously undocumented cultural resources exist.

Matthew Harris (Senior Archaeologist) and Vanessa Zeoli (Architectural Historian) served as Principal Investigators for this project. Historian and Graduate Archaeologist Joel Dworsky conducted the background research for the study and built the prehistoric/historic archaeological sensitivity model. Mr. Harris, Mr. Dworsky, and Ms. Zeoli were the principal authors of this report, but contributions were made by Senior Archaeologists Daniel Cassidey and Andrew Wyatt. Mr. Dworsky produced the graphics for the report.

2.0 Methodology

The purpose of this study is to gather information about previously documented archaeological and historic architectural resources and to assess the likelihood for the APE to contain cultural resources not previously documented.

2.1 *Background Research*

Background research was conducted online via MHC's Massachusetts Cultural Resource Information System (MACRIS) to determine if there were any cultural resources in the project area listed in or eligible for listing in the NRHP or SRHP. Information was also gathered on resources that were inventoried and documented in MHC's files, but may not have been evaluated for NRHP eligibility. To ensure URS had the most up-to-date information, the online research was followed by a visit to MHC to gather any additional information not contained in MACRIS. Information gathered during the visit to MHC included NRHP nominations, inventory forms, site forms, and any reports for cultural resource investigations that were previously conducted in the project area.

Additional online research was conducted to gather historical maps, atlases, aerial photographs, and city property records—as well as secondary source materials, like local and regional histories—in order to establish prehistoric and historic contexts. The NRHP website was also consulted to ensure the most up-to-date information was collected on resources listed in the NRHP, as well as on those that had been issued a determination of eligibility (DOE) from the Keeper of the National Register. Information gathered during background research was used to guide the development of the APE.

As part of the background research for this project, an archaeological literature review was conducted. During the literature review process, information about known archaeological sites in the region surrounding the project APE was collected at the MHC archives. Archaeological site forms were collected for any sites found to be located within a 1-kilometer radius of the proposed rail modifications. Relevant sites were determined through an examination of the spatial locations of the known sites, as recorded on maps at the aforementioned facility. Additionally, pertinent archaeological survey reports were consulted to provide information about the history of archaeological research conducted in the vicinity, as well as to provide additional information about the extent, integrity, and significance of the known archaeological sites identified during the early phase of the literature review. The archaeological data collected from the MHC was combined with relevant historic maps, documents, environmental surveys, journal articles, and regional histories. This information was synthesized and distilled into a series of determinations about the archaeological potential of the study area surrounding the project APE.

2.2 *Field Visit*

2.2.1 *Archaeology*

No archaeological field reconnaissance was undertaken within the APE in Massachusetts. The entirety of the proposed project APE is confined to the extant railroad bed. The proposed track modification that defines the project APE for the Capitol Corridor Rail Transit Study calls for the reintroduction of a secondary line of track paralleling the extant tract between Nashua, New Hampshire, and Lowell, Massachusetts. This secondary track existed until the 1960s, when commuter rail service was discontinued and the secondary track removed (Wallace 2001). As the entirety of the project APE consists of a thick bed of crushed bluestone gravel, which prevents visual access to the soil, there was no need from a visual inspection to be undertaken.

2.2.2 *Historic Architecture*

After reviewing the background research, a field visit was conducted of the project area March 25-29, 2014. The field visit consisted of a windshield survey to assess the general conditions of historic architectural resources in the APE. Historic architectural resources are defined as aboveground buildings, structures, objects, districts, or landscapes. The purpose of this study is not intended to definitively identify and document every historic aboveground resource in the APE; rather, it only inventories any previously documented historic properties that are listed in or eligible for listing in the SRHP and NRHP and indicates the likelihood that previously undocumented aboveground resources exist. Section 5 presents the results of the historic architectural investigation.

2.3 *Definition of the Area of Potential Effects*

The area of potential effects (APE) encompasses all areas where construction activities could directly or indirectly impact significant historic properties (Figure 2). In general terms, an APE is defined as "the geographic area or areas within which an undertaking may directly or indirectly cause changes in the character or use of historic properties, if any such properties exist" (36 CFR §800.16[d], amended 2004).

The APE includes all areas affected during the construction of the project and by the end result of the improvements. Development of the APE took into consideration potential visual effects, auditory effects, direct and indirect effects, beneficial as well as adverse effects, physical effects, and changes in the way the land or historic properties are used. A project may have a single APE that includes all these effects, or may generate multiple APEs—one each for visual effects, direct effects, etc.—which may or may not overlap.

The Lowell Study Area is comprised of an area 1 kilometer on either side of the extant railroad corridor that runs along the banks of the Merrimack River (see Figure 2). This 9-mile corridor runs south from the state border with New Hampshire through the municipalities of Tyngsborough, Chelmsford, and Lowell. The study area terminates at the existing rail line's intersection with the extant commuter rail station in western Lowell. From this junction, the existing line continues southeast toward the center of Lowell, where there is an existing commuter rail station running service between Lowell and Boston. Even though the APE is confined to the extant rail corridor, it was decided that the Lowell Study Area should be comprised of a 1-kilometer buffer on either side of the extant railroad bed to ensure that a sufficient number of known archaeological sites were included within the study area dataset and afford a reasonable sample from which to draw conclusions about the archaeological sensitivity of the APE.

The APE for historic architectural resources is the area within which the proposed undertaking could reasonably be expected to have a physical or visual effect on historic properties of this type, if any exist. The portion of the project in Massachusetts only includes the railroad ROW, where a second track will be added. This area is the direct APE. Since new track will only be added to areas that already contain a track, there is no potential for visual impact. As a result, the APE was confined to the limits-of-disturbance (LOD) in the areas where the new track would be laid. See 60Appendix B for a map showing the areas proposed for a new track.

The APE was developed based upon the preliminary project plans and renderings. If project plans are modified from those included in this study, the APE will have to be adjusted accordingly and additional research and survey will be necessary to evaluate previously unsurveyed areas and the effects of the project on potentially significant archaeological or historic architectural resources.

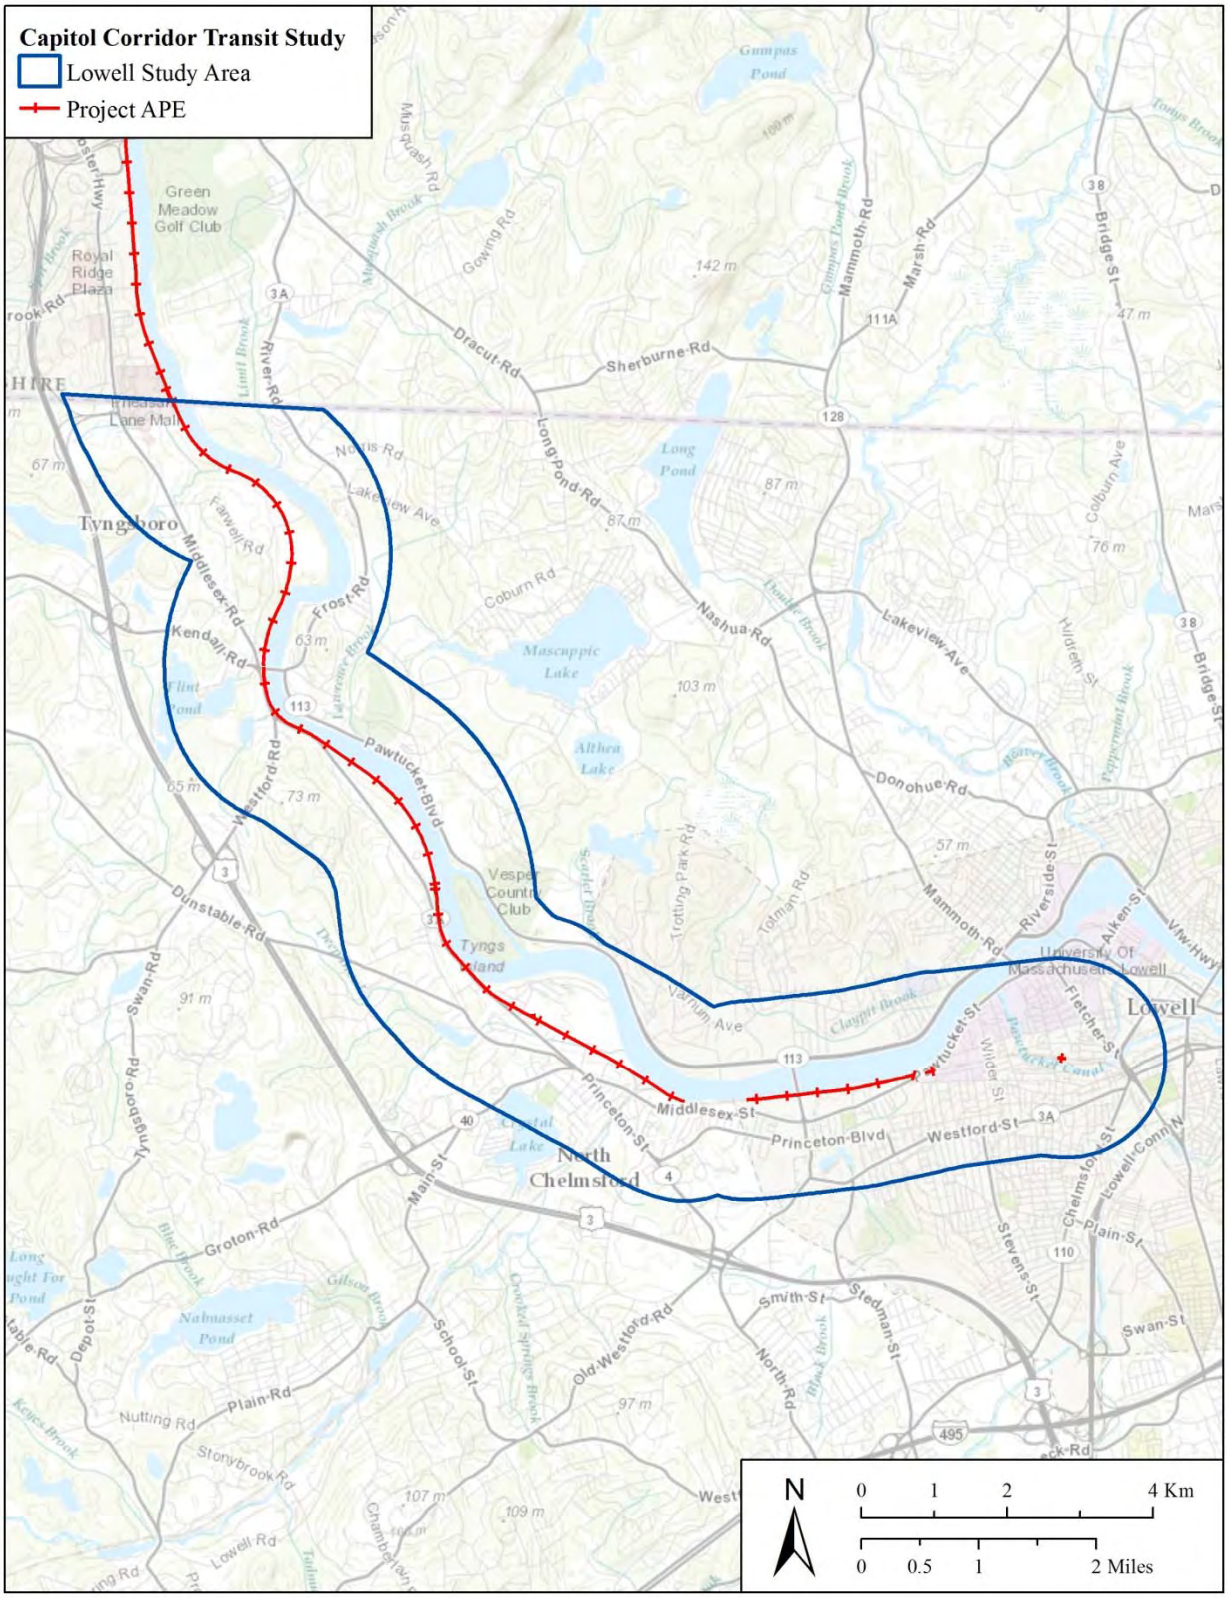

Figure 2 - A map showing the location of the project APE and the Lowell Study Area.

3.0 Environmental Background

3.1 *Physiography and Drainage*

The study area is located in the Seaboard Lowland portion of the New England physiographic province and are drained by the Merrimack River (Fenneman 1938) (Figure 3). The principal tributary of the Merrimack River near the study area is the Concord River, which joins the Merrimack to the east of the project area downstream from Pawtucket Falls. All project components are located within the Merrimack River Valley. Glacial outwash terraces and plains, stream terraces, and floodplains of the Merrimack River are the principal landforms.

3.2 *Geology and Soils*

The Lowell Study Area sits atop five principal types of bedrock (Zen et. al 1983). Figure 4 shows that the most dominant bedrock within the Lowell Study Area is part of the Berwick Formation, which formed during the Silurian period (Nicholson et al. 2006). The rock within the Berwick Formation was created through the metamorphic process (heat and pressure), which changed the chemical composition of the rock. The underlying bedrock in the areas contained within this formation is made of metamorphosed calcareous sandstone or siltstone, with occasional inclusions of muscovite schist. The next most common type of bedrock within the Lowell Study Area is granite. There are three principal granite formations occurring within the study area, and they tend to alternate with deposits of the aforementioned Berwick Formation. These three granite formations include: Chelmsford granite (Lower Devonian), Ayer granite (Lower Silurian), and Andover granite (Silurian or Ordovician) (Nicholson et al. 2006). Of these three, the most recent is Chelmsford granite, which is intrusive into the surrounding Berwick Formation, having emerged between 417 and 354 million years ago, during the Devonian period (Lambert 2006:196). The majority of the rock formations within the study area, with the notable exception of the aforementioned Chelmsford granite formation, were created during the Silurian period, dating to between roughly 443 and 417 million years ago (Lambert 2006:194). Sandwiched between the Ayers granite formation in the south of the Lowell Study Area and the southernmost band of the Berwick Formation is situated a band of Tadmuck Brook schist that may be contemporaneous with the Berwick Formation, having similarly formed in the Silurian period (Nicholson et al. 2006).

Soil data for the project area was derived from the United States Department of Agriculture's Web Soils online repository and is summarized in Table 1 (USDA 2010). Downstream from Tyng Island, all the way to the termination of the proposed rail modifications, is an area that is dominated by soils classified as undorthents (fill soil) and/or urban land (Figure 5). Ascertaining a dominant soil component for the Lowell Study Area—apart from the fill and urban land—is difficult, given the linear nature of the project area. Furthermore, many soil types that occur within the study buffer never actually encounter the APE for the proposed rail modifications and would therefore skew the data. Therefore, to get a more accurate idea of the dominant soil types, a 15-mile buffer of the proposed rail modifications was established and only soil types that fell within its confines were analyzed. Table 1 shows the breakdown of soil types in this buffer.

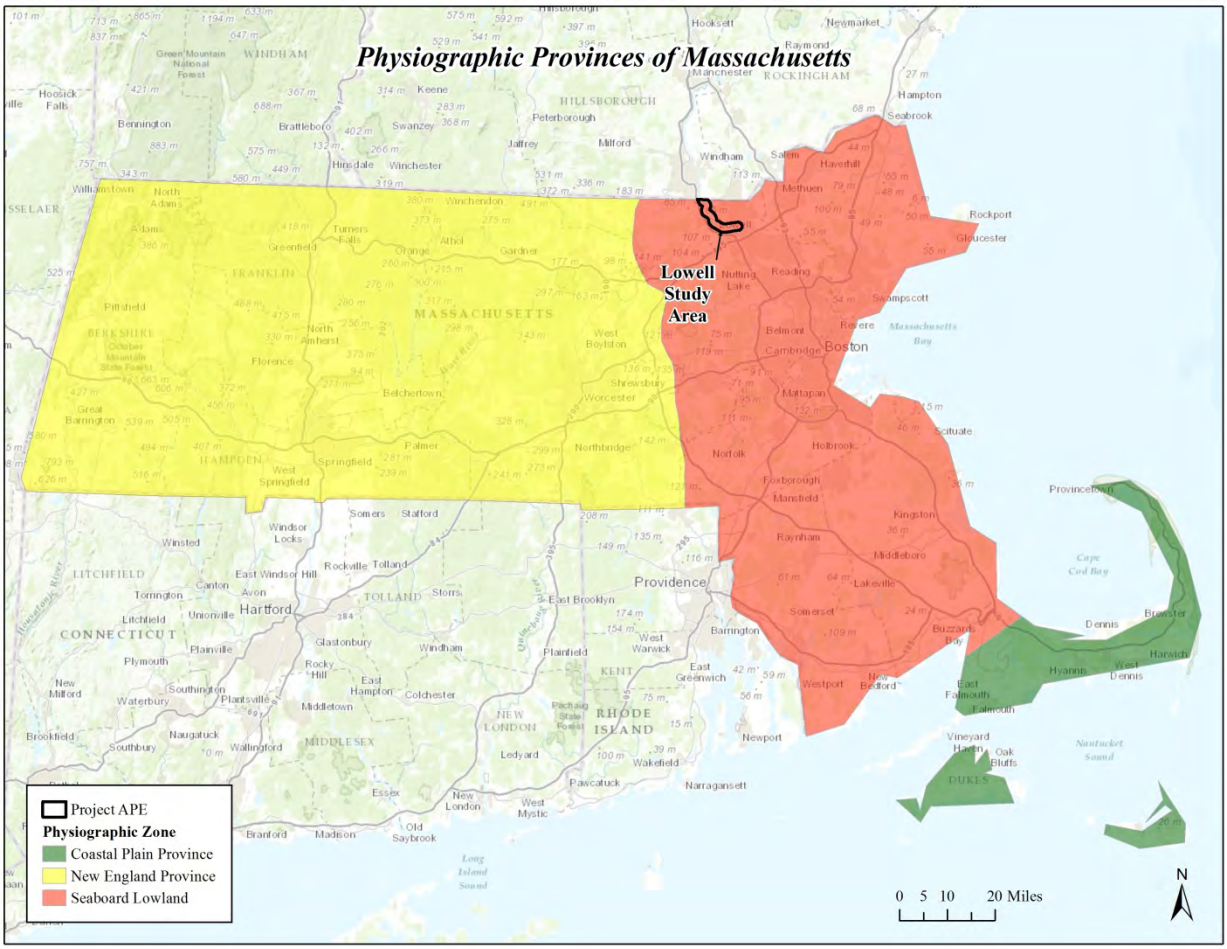

Figure 3 - Massachusetts physiographic zones (Source: U.S. Geological Survey 1983:317).

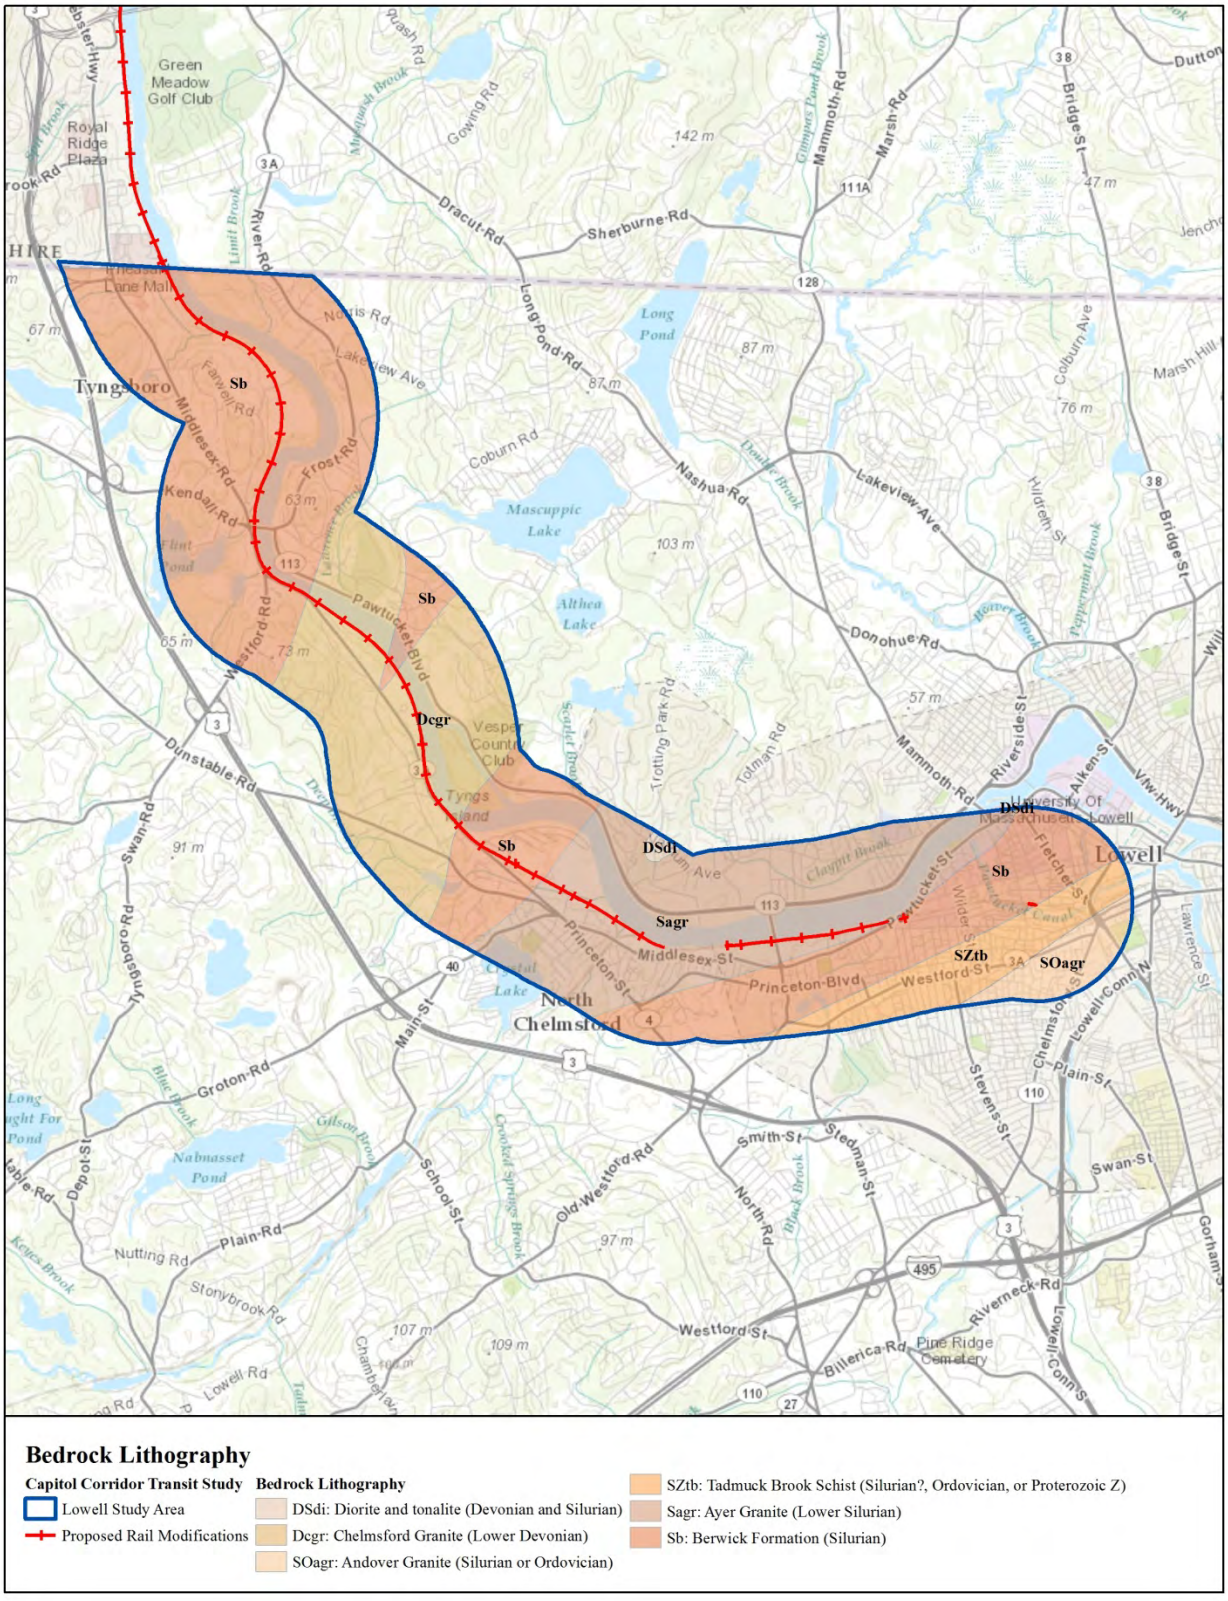

Figure 4 - Bedrock lithography of the Lowell Study Area (Source: Nicholson et al. 2006).

3.3 *Paleoenvironment*

As glacial ice ablated in New Hampshire and northern Massachusetts between circa 14,600 and 12,600 B.P. (Ridge 2003), thick till was emplaced on uplands, and three successively higher proglacial lakes occupied what would become the Merrimack River Valley (Lakes Tyngsboro, Merrimack, and Hooksett, from south to north). Koteff et al. (1984) suggests that these lakes drained sometime after 13,000 B.P., and the southern margin of the Laurentide ice sheet retreated from the upper Merrimack drainage by circa 12,000 B.P. (Ridge 2003). During this interval, the ancestral Merrimack River began eroding and reworking the glaciolacustrine sediments and constructing a series of lower stream terraces. Aeolian deposition capped stream terrace and proglacial lake deposits in places (Koteff et al. 1984:391–392), a process that continued into the late Holocene based on Dincauze's (1976:10–11) interpretation of soil parent material at the Neville Site.

Low-growing tundra vegetation, consisting of mosses, ferns, sedges, and grasses—along with dwarf birch and alder—colonized newly deglaciated landscapes. Pollen-based vegetation reconstructions for northern New England vary regarding the earliest trees to colonize tundra. Davis (1981) suggests that spruce dominated the first patchy, open woodlands in northern Massachusetts, as well as southeastern and central New Hampshire, between circa 12,700 and 11,800 B.P. This open woodland bordered tundra to the west and north. At the same time, a mixed woodland composed of poplar, spruce, and jack pine/red pine existed in the vicinity of Nashua, New Hampshire. After 12,000 B.P., the mixed woodland had moved north and west, replacing open woodland in the vicinity of Concord, New Hampshire, while more closed forests dominated by spruce (together with fir, birches, and poplar) had developed in southeastern New Hampshire and northern Massachusetts (Davis and Jacobson 1985). Newby et al. (2005) have linked a retraction of spruce/fir forests to southern Maine and southeastern New Hampshire and expansion of tundra between circa 11,000 and 10,000 B.P. to the Younger Dryas climate episode, coinciding with the arrival of Paleoindians in northern New England.

As in the case of flora, faunal communities of the Late Glacial had no modern analogs. These communities were characterized by the association of a number of Late Pleistocene species that are either extinct (e.g., mammoth, mastodon) or regionally extirpated (e.g., caribou), with other species (e.g., deer, moose, black bear) that have persisted in the area into the modern period (Lundelius et al. 1983).

Although there is no archaeological evidence in New England for Paleoindian exploitation of mammoth or mastodon, radiocarbon dates for these and other extinct species indicate that they were available to at least the earliest Paleoindian groups. Small fragments of calcined caribou bone have been recovered from the Whipple and Bull Brook Paleoindian sites (Spiess et al. 1998:226).

Rapid warming after the Younger Dryas fostered the arrival of oak, white pine, and maple into northern New England between 10,000 and 9000 B.P. These species quickly replaced spruce and fir, resulting in a new composition of the closed forests of southeastern New Hampshire/northern Massachusetts and southern Maine that came to be dominated by pine. Hemlock, beech, and birch followed between 9000 and 8000 B.P. The growing numbers and density of mast-producing species in early Holocene forests would have increased the carrying capacity of the environment, resulting in higher terrestrial game populations and diversified subsistence opportunities for Native American groups. Between 9000 and 6000 B.P., the center of pine abundance moved northwest, and forests composed of pine, birch, maple, beech, and hemlock became dominant. Other mast-bearing trees, hickory and chestnut, arrived in northern New England at 5000 and 2000 B.P., respectively (Davis 1981; Gaudreau 1988).

Early historic period vegetation patterns in the Northeast include a conifer-hardwood forest region in the northern sections and deciduous forests in the southern portions. This modern ecotone extended from southern Maine west along the Massachusetts-New Hampshire border. Pollen records indicate that the ecotone between the two major zones was established in the early Holocene and became more pronounced between 8000 and 6000 B.P. While the ecotone was stable from the early Holocene, the species composition of the two forest zones continued to change throughout the late Holocene (Gaudreau 1988).

4.0 General Cultural and Historic Background

4.1 *Prehistoric Background*

4.1.1 *The Paleoindian Period (Circa 11,500–9400 B.P.)*

Although several sites south of New England (i.e., Meadowcroft, Cactus Hill, Miles Point) may represent pre-Paleoindian habitation sites, the earliest documented occupation of New England and the Maritimes dates to the Paleoindian period, from approximately 11,500 to 9600 B.P. Paleoindian sites are most commonly identified by the presence of distinctive fluted and unfluted laceolate projectile points. Other parts of the toolkit included formal flake tool types and large, bifacial cores. In the greater Northeast, Paleoindian toolkits are marked by a conspicuous use of high-quality cryptocrystalline lithic materials that often originate at considerable distances from their point of discard. The former characteristic is inferred to result from a need for durability over numerous episodes of intensive use at locations distant from sources (Goodyear 1989; Spiess et al. 1998:239–242), while the distances from sites to sources have been used to estimate maximum travel distances.

In a recent synthesis of Paleoindian data for New England and the Maritimes, Spiess et al. (1998: 235–239) proposed a series of five chronological phases for the period based on stylistic changes in projectile forms. The earliest two phases, Bull Brook and Vail-Debert, are roughly coeval. Bull Brook phase fluted points are relatively straight-sided with moderately deep basal concavities and flutes that exceed half the length of the point. Vail-Debert fluted points are generally larger and exhibit the same outline as Bull Brook points, but have deep basal concavities and shorter flutes. Dates for these phases range from circa 11,500 to 10,500 B.P. Fluted points of the following Michaud-Neponset phase are generally narrower and thinner than earlier fluted point styles, display flaring basal ears, and are often fluted to within 10 millimeters of the tip. Crowfield phase fluted points expand markedly from the base, reach maximum width near midpoint, and display long, often multiple flutes. Michaud-Neponset and Crowfield points both display shallow basal concavities compared to Bull Brook and Vail Debert points. Spiess et al. suggested that the Michaud-Neponset phase ranged from 10,310 to 10,070 B.P. The Nicholas phase is the final proposed Paleoindian phase. The Nicholas point is unfluted, small, thin, and expands at the base, similar to Crowfield points. Dates for this phase are few and range from circa 10,120 to 9400 B.P.

In terms of general settlement patterns for the region, Spiess et al. (1998:229–230) have noted that the majority of larger Paleoindian sites contain at least one discrete locus of stone tools and debitage measuring 4 to 8 meters in diameter that are separated by sterile space. The Bull Brook site exhibited 42 such loci, followed by Debert (11 loci), Vail and Michaud (eight loci each), and Bull Brook II (six loci). The non-overlapping character of loci suggests that each represents short-term single occupations at each site. Subsistence data is sparse; however, faunal remains from several sites are limited to calcined medium to large mammal bone. Calcined caribou bone has been identified at the Whipple Site, calcined caribou and beaver bone was present at Bull Brook, and calcined caribou, Arctic fox, and hare have been identified at the Udora Site in Ontario. Extremely small numbers of carbonized fruit and berry seeds have been recovered from the Michaud and Hedden Sites in Maine. Spiess et al. (1998:223–227) suggested that these data support a model of Paleoindian subsistence that is similar in its broad outlines to ethnographic examples from the subarctic region, featuring specialized caribou hunting in some seasons combined with general foraging at other times.

The Whipple Site, located on an outwash terrace above the Ashuelot River in the southwestern corner of the state, is the most extensively excavated Paleoindian site in New Hampshire (Curran 1984, 1994). The site was comprised of three small, spatially separated loci, all of which produced a wide variety of stone

tools types, and two of which contained datable features. Curran assigned the site to the Bull Brook phase of Grimes et al. (1984) based on formal similarities between the Whipple fluted points and those from the Bull Brook Site. Conventional radiocarbon dates from Locus C ranged from 9820 ± 420 B.P. to 11, 430 ± 395 B.P. (Curran 1984:13); however, a weighted mean of three assays yields a date of 10,680±400 B.P. The site contained a large number of calcined cervid bones, three of which were identified as caribou. Speiss et al. (1998:241–242) suggested that the Whipple assemblage is dominated by Champlain Valley chert and appreciable amounts of Munsungun chert from northern Maine, with much lower utilization of more locally available Cheshire quartzite. Curran interpreted the loci as short-term occupations by small family or task groups, and suggests that the loci may not have been coeval based on differing patterns of raw material discard (1984:14–15).

Isolated fluted points and small Paleoindian components have been identified in the Merrimack River Valley. Dincauze (1976:118) reported a fluted point tip from a later context at the Neville Site, and Curran (1994:41–45) described a complete fluted point from potentially intact subsurface contexts at the nearby Smyth Site. Curran (1994:41–43) also discussed the Thornton's Ferry Sites (27-HB-1 and 27-HB-2), both of which are located on sandy glaciofulvial landforms within the former bed of glacial Lake Merrimack. Site 27-HB-2 yielded a single felsite fluted point base, jasper flake tools, and rhyolite debitage in subsoil deposits. At the time of Curran's reporting, no clearly diagnostic Paleoindian artifacts had been recovered from 27-HB-1; however, chert flake tools and debitage of non-local material were recovered at a depth in the subsoil below Middle Archaic types, which were deemed to be possibly Paleoindian. Additional excavation and analysis in 2001 allowed Boisvert and Bennett (2004) to make a convincing case based on stratigraphy, raw material types, and debitage attributes that the site's lower component is Late Paleoindian in age.

4.1.2 *The Archaic Period (Circa 9400–2500 B.P.)*

The Archaic period exhibits an increase in the density and horizontal dispersal of archaeological remains. It is characterized by a reliance on both animals and wild plant resources, which became increasingly stabilized and broad based over time. Group organization was presumed to still be fairly mobile, making use of seasonally available resources. Caldwell (1958) has termed the maximizing adaptation (scheduled hunter-forager) to the environment in the Eastern woodlands during the Archaic period "primary forest efficiency." Group size gradually increased during this period, culminating in a fairly complex society in the Late Archaic.

The Early Archaic period (circa 9400–7000 B.P.) is marked by the end of the Pleistocene glacial climate and extinction of megafauna. To date, evidence of Early Archaic occupations is much more common in southeastern North America than in the Northeast. In addition, the southeastern sequence suggests a transition from Paleoindian to Early Archaic assemblages, which has not yet been demonstrated for the Northeast. Prior to 1970, there was virtually no evidence of any northeastern sites dating to the Early or Middle Archaic periods. In the last three decades, considerable information has been obtained to fill in that gap, but the picture is still incomplete. The period is characterized by greater diversity in projectile point forms and increasing reliance on diverse species of Holocene fauna, including white-tailed deer, anadromous fish, birds, and turtle (Petersen et al. 1986:9).

George Nicholas has been a frequent and vocal proponent of the idea that early Holocene occupations in the Northeast were much more abundant than was previously thought, and that they operated within an environment that was much more productive than originally described. He has identified former glacial lake basins as locations that are likely to have been established as resource-rich mosaics within a changing and somewhat unpredictable early Holocene landscape (Nicholas 1983, 1988).

Early Archaic projectile points have been found in relatively isolated contexts from the Lakes Region of New Hampshire to the lower coastal tributaries of northeastern Massachusetts (Bunker 1988:6). At least three Early Archaic components referable to Robinson's (1992) Gulf of Maine Archaic tradition are known for the Merrimack River Valley. The first to be excavated was the Weirs Beach Site, located at the outlet of Lake Winnipesauke (Bolian 1980; Maymon and Bolian 1992). The stratified Early Archaic component featured large amounts of quartz debitage, cores, steep-bite quartz endscrapers, and groundstone rods. Radiocarbon dates of 9155 ± 395 B.P. and 8985 ± 120 B.P. on wood charcoal from features placed the site in the Early Archaic subperiod. The Eddy Site (27-HB-0078), located on a stream terrace of the Merrimack River, was subjected to test excavations in 1985 in advance of topsoil mining (Bunker 1992). The site yielded a stratified sequence of Middle Archaic through Woodland occupations in the upper meter of alluvial deposits. Between approximately 1 meter and 1.77 meters below surface, four strata were encountered, each of which produced small quartz-dominated assemblages at the upper contacts of each stratum. Tools included unifaces, other flake tools, hammerstones, and one adze fragment. Quartz was the primary lithic material for cores and debitage. Radiocarbon dates on charcoal from 1.29 to 1.62 meters below surface range from 7830 ± 100 B.P. to 7595 ± 120 B.P. In 1993, excavations in the town of Merrimack by Louis Berger and Associates recovered an Early Archaic campsite at Site 27-HB-160 radiocarbon-dated at 8690 +80 B.P. (Carini 1994:IX-1). The site produced an assemblage of early-stage quartz debitage, chert bifacial reduction debris, unifacial tools, nuts, berries, and mammal bones. Neither site yielded projectile points; a minor role for bifaces and stone projectile points appears to be characteristic of pre-Neville complex Middle and Early Archaic occupations of the Gulf of Maine Archaic tradition (Robinson 1992:69).

The Middle Archaic, circa 7000–5000 B.P., is associated with warmer and drier climatic conditions. By this period, modern floral communities were established, characterized by mast-producing hardwoods. Rivers stabilized during this time and wetland and lake areas were reduced in size. Hunting continued to be important, and fish may have become a more predictable resource. There is evidence for shellfish exploitation during this period. Excavations at the Neville Site in Manchester documented the Neville stemmed point type, dating between 7800 and 7000 B.P., and the Stark stemmed point type, dating between about 7600 and 6400 B.P. (Dincauze 1976). In addition, the Merrimack point type was identified as dating to the end of the Middle Archaic period, close to 6000 B.P. The Neville and Stark point types are similar in style and age to the Stanly and Morrow Mountain types that Coe (1964) defined earlier in the Southeast, but the Merrimack type appears to be more spatially restricted.

After publication of the Neville Site research, sites and isolated finds associated with these Middle Archaic complexes were increasingly recognized and reported throughout the Northeast. The Neville and Stark types have proved to be relatively common throughout New England. In the lower Merrimack River Valley, excavations at the Eddy Site revealed another substantial Middle Archaic occupation focused on riverine exploitation, and evidence for upland mast forest exploitation is documented at the Smolt Site (Kenyon 1983). Abundant evidence for lithic reduction activities comes from assemblages recovered from several Middle Archaic sites in the Lakes Region of central New Hampshire (Cassedy 1984; Starbuck 1983).

The accumulated data for the Middle Archaic period in the Northeast suggest that, during this period, the prehistoric inhabitants were forming themselves into distinct bands and settling into defined territories. These bands were establishing base camps and occupying a greater variety of special-purpose sites in a carefully planned seasonal round (Snow 1980:183). Evidence for the first use of coastal resources, such as shellfish beds, appeared during this period. Several new tool types were developed during this period, including woodworking tools, such as gouges and axes, and large groundstone semi-lunar knives, commonly known by the Eskimo name, "ulu."

The Late Archaic period is generally dated circa 5000–2500 B.P. Prior to the 1960s, Late Archaic sites were virtually the only Archaic period sites recognized in the Northeast. William Ritchie's work at sites like Lamoka Lake in New York had produced his seminal definition of an "Archaic" stage of culture in North American prehistory (Ritchie 1932, 1936), but no earlier complexes were known.

Throughout the Northeast, archaeologists now recognize the Late Archaic period as one in which the numbers and types of sites increased dramatically—what Snow (1980:187) described as the Late Archaic "florescence." Unlike earlier time periods, anyone interpreting Late Archaic assemblages must contend with a sometimes confusing and complex array of data. Based on his work in New York, Ritchie (1994) recognized two major Late Archaic trajectories, the Lamoka and the Laurentian, which overlap in both time and space. Both trajectories are also represented in New England.

Although Ritchie believed Lamoka to be the oldest Late Archaic tradition, more recent research has documented that Laurentian manifestations appeared as early as the last centuries of the sixth millennium B.P. Initially, the Laurentian was subdivided into three phases—Vergennes, Brewerton, and Vosburg—based on projectile point morphology and, to some degree, chronology. These phases extend from about 5500 to 4300 B.P. (Funk 1988:36). Subsequently, the discovery of Otter Creek and Brewerton Side Notched projectile points dating to the fifth and early sixth millennia B.P. led Funk to posit a "Proto-Laurentian" assemblage composed of "broad side notched points with ground bases and notches generally resembling Otter Creek and Brewerton side notched points" (Funk 1988:29), along with "biface knives, a variety of unifacial end and side scrapers, and common forms of 'rough stone' tools such as hammerstones and pitted stones" (Funk 1991:9). Funk and others (Tuck 1977:37) suggested that the Proto-Laurentian assemblages are "closely allied with Middle Archaic complexes of the Southeast and Midwest, chiefly identified by Raddatz, Modoc Side Notched, Big Sandy, and other large, notched points similar to the Otter Creek type" (Funk 1991:9).

What Ritchie first defined as the Lamoka culture in the Finger Lakes region has been shown to be associated with a horizon of small, narrow-stemmed projectile points that extends across southern New England, and includes such types as the Sylvan and Wading River forms from the Hudson Valley and southeastern New York, as well as the Squibnocket complex from southern New England.

Following Tuck's (1978) definition of the Lamoka/Sylvan/Squibnocket complexes of central and southern New York and New England as the "Mast Forest Archaic," Snow (1980:226) proposed that we designate the Laurentian complex and related assemblages in northern New England and the St. Lawrence drainage as the "Lake Forest Archaic." As Snow described them, these two complexes coexisted, but each was more common within a particular geographic region. This scheme supposes that there was a "marginal belt of tension between the two coeval zones that persisted throughout the Late Archaic" (Snow 1980:227).

Site density increased relative to the preceding Middle Archaic, although there is no substantial shift in site location (Bunker 1988:11). The subsistence base of the Mast Forest tradition probably consisted of a generalized or diffuse adaptation (Dincauze 1974, 1975). Although white-tailed deer were a major source of food during the Mast Forest Archaic, these were supplemented by a broad range of vegetal foods, particularly nuts, and a broad range of finfish and shellfish resources. Evidence of technological innovations, such as weirs and nets, first appeared in the Late Archaic. Extensive salt marshes developed along the coast and at river mouths, providing a stable environment for increased exploitation of shellfish. Population of coastal areas appears to have increased dramatically at this time, particularly near the end of the Late Archaic period. Sites dating to the Late Archaic have been found throughout the Lakes Region and the Merrimack River drainage, as well as in the lower Androscoggin Valley. Carini (1994:IX-9)

categorized these into "large base camps, small seasonal camps, and both large and small specialized resource procurement stations."

The end of the Archaic has also been commonly called the "Transitional," in reference to its presumed transitional status between the Archaic and Woodland periods. Since research continues to indicate that there is actually a great deal of cultural and biological continuity between the Archaic and the Woodland periods, Snow (1980:235) has suggested that the label "Terminal Archaic" is more appropriate.

As Snow defined it, the hallmark of the early part of the Terminal Archaic is the Susquehanna tradition of broad-stemmed projectile points and their associated assemblages. These points include several regional varieties, including the Genesee, Perkiomen, Snook Kill, and Susquehanna Broad types in New York. This Susquehanna tradition of broad-stemmed projectile points is analogous to Coe's (1964) Savannah River type from the southeastern United States. Characteristics of the Susquehanna tradition include a marked preference for a riverine adaptation and a predilection for the fine-grained lithic resources of the Piedmont province, including rhyolite, felsite, argillite, and slate (Dincauze 1975:27; Turnbaugh 1975:54).

The latter portion of the Terminal Archaic period is marked by the appearance of narrow, tapered Orient Fishtail projectile points. Named for the type locations at Orient Point on eastern Long Island, Orient Fishtail points tend to be found on Long Island, in the Hudson Valley, and in southern New England (Ritchie 1971).

A marked increase in ritualistic behavior is also a feature of the Terminal Archaic cultures. Red ochre cremation burials with an assortment of grave goods are common from sites of this period in northern Massachusetts, and a cremation burial containing a broad-bladed point was excavated from the Litchfield Site, southeast of the current project (Bunker 1988).

Another hallmark of the Terminal Archaic is the appearance of steatite (soapstone) cooking vessels toward the end of the Susquehanna tradition (which continued throughout the Orient tradition). The presence of these large steatite vessels suggests that "the people who made, traded, and used [them] had reached a point in the evolution of their settlement and subsistence systems where the use of heavy cooking vessels was advantageous" (Snow 1980:240). This implies that these people lived in more sedentary settlements, utilizing foodstuffs that required long processing with heat.

4.1.3 *The Woodland Period (Circa 2500–300 B.P.)*

The Early Woodland period in much of the Northeast is represented by the Meadowood phase, with its distinctive thin, side-notched projectile points and the first widespread appearance of ceramic vessels. This pottery, which has been given the type name Vinette I, appears on some Terminal Archaic sites, but did not become common until the Meadowood phase. The presence of pottery has long been one of the key defining attributes to separate sites of the Woodland period from those of the Archaic, in the absence of radiocarbon dates or chronologically distinctive stone artifacts. In addition to Meadowood projectile points, Adena, Rossville, and Lagoon points are also associated with this time period. Rossville and Lagoon points are particularly common on Early Woodland sites in the coastal areas of southern New England and Long Island Sound.

Early Woodland cultures in New England show considerable variation from the patterns seen in central and western New York. Sites in the latter regions show much greater participation in widespread trade networks that extended from the Gulf of Mexico to the Great Lakes. Exotic seashells, distinctive types of stone, and native metals like copper and lead moved between the far-flung reaches of the network. This

trade network was also associated with an elaborate mortuary ceremonialism that included burying many of the exotic traded items in graves with the dead. The presumed core of this system was the Adena tradition of the Ohio River drainage, to which numerous elaborate sites with well-stocked graves have been attributed.

Adena/Middlesex-related burial sites have been found as far east as New England and the Maritime provinces, where they appear to be most common in the St. Lawrence and Connecticut River drainages. Cemetery sites near Lake Champlain and in New Brunswick have yielded a wide variety of objects associated with this complex, such as blocked-end smoking pipes, copper and shell ornaments, as well as stone tools from distant sources, such as Indiana, Ohio, Ontario, and Quebec.

Throughout the Northeast, Early Woodland habitation sites are generally less common than the cemetery sites, which has skewed the picture of the prehistoric lifestyles for this period. Many Northeastern Early Woodland burial sites actually predate classic Adena in Ohio, and it is likely that the Early Woodland manifestations in this region represent a complex interplay of traditions. Early ceramic vessels tend to be thin and grit tempered. Settlement patterns, at least in the earliest portion of the Woodland period, exhibit little variation from preceding Archaic patterns (Kenyon and McDowell 1983:21).

By the time of the Middle Woodland period, significant changes in subsistence practices began to appear in much of eastern North America. The use of plant foods started to intensify, and the cultivation of domesticated plants spread into the region between 1500 and 1000 B.P. This was often accompanied by increased sedentism in the settlement pattern, as people began to live in larger congregations for longer periods of time. Northern New England appears to have been situated on the climatic and cultural margins of plant cultivation, and it is still not clear how extensive a role domesticated plants played in the late prehistoric subsistence strategy. Seasonal shifts in settlement and subsistence may have characterized much of eastern New England. Inhabitants may have alternated between coastal resources in the fall, winter, and spring, and interior resources during the summer months (Bourque 1973; Snow 1980:301). Settlements from the later Woodland appear to have been localized, and there is no evidence for long-distance trade until the arrival of Europeans (Snow 1980:319), with the possible exception of lithic raw material. A slow trend toward population nucleation and increased sedentism characterizes the Woodland period, especially near the coast and along estuary heads (Lavin 1988:110, 114).

Local quartz was commonly utilized for stone tools throughout the Woodland period, but non-local materials, such as jasper and chalcedony, were also used. The earliest Middle Woodland point types include Fox Creek and Jack's Reef, and triangular Levanna points began to be used circa A.D. 800–1000. Near the end of the Late Woodland period, smaller Madison triangular points became common. At approximately the same time, the ceramic technology shifted from elongated, thick-walled vessels to globular, thin-walled vessels. The shoulders and collars of these vessels were often incised and appliquéd with elaborate decorations.

The late prehistoric and Contact period native inhabitants of northern Massachusetts along the Merrimack River were members of the Penacook, a part of the larger Algonkian culture, which encompassed much of the Northeast beyond the Iroquoian tribes of New York and the St. Lawrence River. The Penacook had substantial settlements along the Merrimack at the time of contact and would yearly gather in large numbers to harvest anadromous fish. These gatherings would generally take place at the numerous falls along the Merrimack, including the Amoskeag Falls (location of the Neville Site) and Pawtucket Falls in the area that is now Lowell. By the time European explorers made contact with the natives in this region, they had already been decimated by the spread of disease which started when Europeans first encountered native groups along the coastal regions in the early seventeenth century. By the time of King Philip's War, the population of the Penacook at the village of Wamesit near the Pawtucket Falls had been further

reduced due to intertribal warfare with the Mohawk, who had extracted a terrible toll upon the Penacook, reducing their number to just a fraction of what it had been (Cogley 1999:151–154; Pendergast 1996:7). The bloody Indian wars of the latter part of the seventeenth century prompted many members of the Penacook, especially those under the leadership of the sachem Wannalancet, to remove to Canada and wait out the conflict, returning in 1685 (Piotrowski 2002:18). In response to the threat of further conflict with the Mohawk and of additional conflict with the English, Wannalancet sold the remaining Penacook lands near Wamesit to Johnathan Tyng in 1686 (Piotrowski 2002:18). By this point, most of the Penacook had removed to the area around Quebec in Canada. Other members of the Penacook who remained in the region joined in the Indian wars, which led to further loss both of lives and territory (Piotrowski 2002:19).

4.2 *Historic Background*

The region that comprises the Lowell Study area is made of three modern municipalities—namely, the city of Lowell, the town of Chelmsford, and the town of Tyngsborough. Of these three modern areas, only Chelmsford has maintained any consistency of name since its inception. The city of Lowell was once known as East Chelmsford, prior to the great industrial boom that took place there. Tyngsborough was once part of the town of Dunstable, a large portion of which is now part of New Hampshire—specifically, the area around the present-day city of Nashua. While the early histories of these communities are largely similar, Lowell headed off on a radically different course in the first quarter of the nineteenth century. This departure was an industrial boom that radically transformed the agrarian community of East Chelmsford into the industrial powerhouse of the city of Lowell, Massachusetts. Due to the intensity of settlement in the part of the study area occurring within Lowell, the likelihood of encountering historic resources there is increased. Therefore, additional time will be spent describing the history of the town of Lowell to ensure that proper context is provided for the examination of potentially surviving cultural resources within the study area.

4.2.1 *Early Settlement*

The story of Tyngsborough begins with the establishment of the settlement of Dunstable, Massachusetts. Early forays into the region were largely limited to ventures designed to carry on trade with the native populations of the Merrimack Valley. One such venture occurred in 1665 and was executed by John Cromwell, a fur trader who established a trading post along the Merrimac near a small falls. This experiment did not endure and was subsequently abandoned (Fox 1846:21). In 1673, the land where Tyngsborough now lies was part of a 200-square-mile land grant made to Edward Tyng (Fox 1846:16–17). Tyng established the town of Dunstable—named after his native town of Dunstable, England—near the confluence of the Merrimack and Nashua Rivers (the site of modern-day Nashua City). This early settlement encompassed the whole of the Lowell Study Area, and a great deal more territory besides. The initial settlement was successful in establishing small communities, but little else, as the events of the final quarter of the seventeenth century shifted focus away from community growth and toward community protection, stagnating the European settlement of the region well into the eighteenth century (Fox 1846:68).

In 1675, the region became the scene of a bloody conflict between the native peoples of New England and European settlers that would become known as King Philip's War (Fox 1846:28). King Philip was the European name given to Metacomet, the grand sachem of the Wampanoag, who had been baptized as and given the Christian name Philip as a child (Waters 1917:84). This war raged for three years, although fighting slowed after the death of Metacomet on August 12, 1676 (Waters 1917:85; Allen 1820:161). A native raid on Chelmsford on March 18, 1676 resulted in the burning of up to 15 homes and the deaths of several citizens who were ambushed while crossing the river to tend their cattle (Waters 1917:113; Cowley 1868:20). Additional citizens died as a result of participating in the fighting on behalf of the

Massachusetts militia (Waters 1917:125). Not all of the native peoples in the area were hostile to the people of Chelmsford; in fact, the town was befriended by Wannalancet of the Wamesits, who occupied the area now known as Lowell (Allen 1820:157). Wannalancet aided the English settlers by using his influence to prevent attacks on their settlements and warning the communities of impending attacks from hostile native groups, like the Mohawk (Waters 1917:125; Old Residents' Historical Association of Lowell Mass 1874:393–394; Allen 1820:157; Cowley 1862:16). While Wannalancet and his people abstained from the conflict, the war seeded deep mistrust of all Indians across the region, and they were frequently harassed or attacked by groups of English settlers (Waters 1917:125; Cowley 1862:16). So in 1677, Wannalancet and his people departed the region and settled for a time in Canada (Fox 1846:21; Contributions of the Old Residents' Historical Association of Lowell Mass 1874:394; Cowley 1862:17). He returned in 1678 and resumed occupation in the region until 1686, when he sold his land to John Tyng and once more removed to Canada to live with the St. Francis Indians (Contributions of the Old Residents' Historical Association of Lowell Mass 1874: 395; Allen 1820: 27, 45; Cowley 1868:21). Wannalancet and his people had sustained losses of both territory and population at the hands of the English, who had stolen land, sold natives into slavery, and frequently broke treaties (Waters 1917:126). However, when King William's War erupted in the 1690s, the English sought out their old friend in Canada and persuaded him to return to his homeland to help mediate the conflict. Wannalancet obliged, but never again made it back to his people, dying in 1696, and was subsequently buried by his friend John Tyng (Contributions of the Old Residents' Historical Association of Lowell Mass 1874:398).

While King Philip's War had caused many of the occupants of the nascent towns of Chelmsford and Dunstable to flee, the cessation of the conflict in 1678 prompted many to return and the town grew once more under the umbrella of a tenuous peace (Fox 1846:37; Water 1917:127). When William and Mary took over the throne of England, the king of France, who had hoped that England would once more have become a Catholic country under James II, took up the cause of the Stuarts and declared war on the Protestant couple (Old Residents' Historical Association of Lowell Mass 1874: 396; Waters 1917:127). The resulting conflict came to be known as King William's War, noted above, which in 1690 began in the New World when French troops marched south from Canada with their native allies and attacked Schenectady, New York (Waters 1917:127). Once again, the region fell into conflict and the colonists of Dunstable and Chelmsford lived in constant and often justified fear of attack (Waters 1917:132–133). During this time, the towns were frequently garrisoned (Fox 1846:65–68, 82, 103). After years of bitter fighting in Europe and the colonies, Britain and France came once more to peace, signing the treaty of Ryswick in 1697. The conflict resolved nothing and much of the territory that had been won or lost during the conflict was restored to its previous owners (Waters 1917:138). Just five short years later, in 1702, Britain once more found itself at war with both France and Spain. The North American side of this conflict came to be known as Queen Anne's War, but this was only really a theater of the larger War of Spanish Succession, a Europe-wide contest to preserve the military balance of power in Europe, as well as the balance of power between European Protestants and Catholics, which had been established during the preceding Thirty Years War (Waters 1917:138). This war raged for 11 years, until the signing of the Treaty of Utrecht in 1713, which saw Britain acquire new North American territories like Arcadia (Waters 1917:138). Despite the positive outcome of these conflicts, the constant fighting and fear of Indian attacks that permeated every aspect of a European settler's life caused the efforts at establishing and expanding settlements to stagnate until well into the early eighteenth century (Fox 1846:68).

4.2.2 *Colonial Period*

During the latter portion of the seventeenth century and into the early part of the eighteenth century, many land disputes between competing charters and land grants occurred between the established colony of Massachusetts and the newly formed colony of New Hampshire. For much of this time, both colonies laid claim to the town of Dunstable and its surrounding territory, part of the original Tyng grant. This debate continued for well over 50 years, until the boundary between the two rival colonies was settled in

1741 (Stearns 1986:v; Fox 1846:147; Peters 2006:8). This decision split the original Tyng grant in half, with the northern portion and town of Dunstable going to New Hampshire and the southern portion of Dunstable going to Massachusetts (Fox 1846:147; Peters 2006:8). It was during this time that Massachusetts created the municipality of Tyngsborough out of part of the southern portion of their new territory. Thus, this boundary settlement led to the creation of Dunstable and Tyngsborough in Massachusetts and the town of Dunstable in New Hampshire (Fox 1846:150).

The first half of the eighteenth century was punctuated by two further wars—the War of Jenkins' Ear and King George's War, which saw men from Massachusetts involved in the conflicts, but did not have the same harrowing effect on the region as earlier wars, as the action was more distant (Waters 1917:157). The second half of the eighteenth century saw two additional wars, the French and Indian War and the American Revolution. Men from the region participated in both of these conflicts, but the fighting occurred elsewhere (Fox 1846:159–168). The result of the French and Indian War, which concluded in 1763, saw the French presence in Canada eliminated (Waters 1917:162). Many men from Chelmsford and Tyngsborough fought in this conflict for the British crown, some losing their lives in the process, but still the town survived and prospered as an agrarian community (Water 1917: 163–189). The French and Indian War had a devastating effect on the surviving native populations in the region, who were largely exterminated during this period; this was to be the last of the Indian wars.

In the wake of the French and Indian War, Britain—although a territorial victor in the conflict—found itself saddled with debt from the defense of its colonies and the prospect of further debt to defend them (Makin 1994:54; Rabushka 2009:715; Nestor 2004:25). Prior to this point, the colonies had been largely exempted from taxation, but the Crown decided to implement several new taxes as a way of replenishing the royal coffers and offsetting the cost for the defense of the North American colonies (Makin 1994:54–58; Nester 2004:24, 28–29). The colonists had reaped the benefits of the military presence during the war, so the people back in Britain thought it only fair that they be asked to contribute to paying off the debt amassed in their defense (Makin 1994:54). The new taxes were poorly received by colonists in North America, who had never paid much tax and who had long enjoyed more or less free trade due to the demonstrated inability of the Crown to enforce previous tax laws and customs duties, which had led to a culture of pervasive smuggling (Makin 1994:57; Nester 2004:24, 29). The new taxes were seen as oppression, especially as no colonist had a voice in parliament, and the result was the American Revolution, yet another conflict during which many individuals from the region were active participants (Cowley 1868:23). Once again, times got tough, men were away at war, and farms and families languished. It was not until the cessation of the conflict in 1789 and the birth of the United States that the region would finally know a sustained peace.

4.2.3 *Post Revolution to Pre-Industrial*

The towns of Tyngsborough and Chelmsford were still largely agrarian by the dawn of the nineteenth century (Figure 6). While water resources had been developed in the eighteenth century and small saw and gristmills flourished, large-scale manufacturing was as yet only a dream (Lowell Historical Society 2006:7; Cowley 1868:24). Communities like Chelmsford and Tyngsborough were still largely isolated due to limited roads and rivers that were made unnavigable by the presence of waterfalls.

The first attempt to improve transportation in the area was achieved in 1796 with the opening of the Pawtucket Canal, which bypassed the Pawtucket Falls and opened up river access to New Hampshire to the north (Lowell Historical Society 2006:7; Cowley 1868:25). The Pawtucket Canal only bypassed one falls and was of limited value as far as transportation, as it only connected the region to nearby Concord, Massachusetts, so it was soon overshadowed (Cowley 1868:25, 27). In 1792, with the formation of the Middlesex Canal Company, a much larger canal project was conceived that would open up the Merrimack River to trade (Mower 1991). When construction was completed in 1804, the canal, which was readily

Figure 6 - A map East Chelmsford by J. G. Hales, c. 1821.

accessible via the nearby town of Middlesex, provided a direct water route north to New Hampshire towns like Concord and south to the populous city of Boston (Mower 1991; Lowell Historical Society 2006:3). The Middlesex Canal came through the area near Tyngsboro, where a lock was established to bypass Wicasee Falls (Mower 1991). This newfound connectivity between towns along the Merrimack prompted new investment in the region and led to the first industrial boom town in the United States.

4.2.4 *Industrial Revolution*

By the first quarter of the nineteenth century, the Merrimack River Valley became the focus of industrial speculation. Due in part to the transportation opportunities made possible by the Middlesex Canal, investors were attracted to the area, which offered substantial waterpower to run large complexes of mills. Early attempts at establishing cotton mills in the region were undertaken in 1813 and 1815, but were small in scale and ultimately failed (Cowley 1868:32). Additional saw and gristmills were established during the second decade of the nineteenth century, as well as a powder mill, all of which met with some success (Cowley 1868:33).

The region might have remained home to only modest industry were it not for one group, now known as the Boston Associates, who—having recently developed a successful mill system in Waltham Massachusetts—went in search of another location to implement their business model (Lowell Historical Society 2006:8; Rosenberg 2011:299; Cowley 1868:42). In 1821, the Boston Associates opened the Merrimack Manufacturing Company in East Chelmsford (Lowell Historical Society 2006:8; Rosenberg 2011:299). This corporation expanded and repurposed the old Pawtucket Canal, using it to direct a controlled volume of water to power their mills, developing and controlling waterpower that they were able to lease to other mills (Rosenberg 2011:299; Cowley 1868:44–45). The Merrimack Manufacturing Company was a huge success, and East Chelmsford was quickly transformed from an agrarian community to a nascent industrial town. The Lock and Canal Company, originally formed in 1792 with the creation of the Pawtucket Canal and subsequently purchased by the Merrimack Manufacturing Company, was reorganized in 1825 as an independent corporation that managed and leased waterpower to other corporations to run their mills (Cowley 1868:49). The Merrimack Manufacturing Company, among others, set about building a community for their workers, which initially was principally comprised of boarding houses for their mill girls (Rosenberg 2011:299). In just five years, the community of East Chelmsford had grown enough to become a town of its own; in 1826, the town of Lowell was incorporated, named in honor of Francis Cabot Lowell of the Boston Associates (Lowell Historical Society 2006:8; Rosenberg 2011:299).

Throughout the first half of the nineteenth century, new mills sprang up all over Lowell. The Hamilton Manufacturing Company was established in 1825 and grew to include five mill buildings and a print shop by 1868 (Cowley 1868:50–51). In 1828, the Appleton Company was established (named for one of the Boston Associates, Nathan Appleton) and had grown to include three mill buildings by 1868 (Cowley 1868:51–52). The Lowell Manufacturing Company was founded the same year as the Appleton Company and had the same number of mill buildings by 1868, although they had a more diversified production than just cotton, as they also produced carpet and wool (worsted mill) (Cowley 1868:52–53). Other mill companies soon followed, including the Middlesex Company (1830), Suffolk Manufacturing Company (1831), Tremont Mills (1831), Lawrence Manufacturing Company (1831), Massachusetts Cotton Mills (1839), and Boott Cotton Mills (named for Kirk Boott of the Boston Associates), which was founded in 1835 (Cowley 1868:53–58). This boom in construction and population created a demand for countless other support industries that built and maintained the city. Thus, substantial groups of carpenters, blacksmiths, machinists, and all manner of other tradesmen were drawn to Lowell to supply its needs (Cowley 1868:61–62). The western part of Lowell had by 1846 found itself the center of the area's lumber industry, where saw and planning mills produced the building materials the ever-growing town required (Cowley 1868:62). By the middle of the nineteenth century, just prior to the outbreak of the

Civil War, the town of Lowell's population had grown to nearly 40,000—nearly 20 times what it had been when the town was incorporated three decades earlier in 1826, and double what it had been when it received its charter as a city in 1836 (Cowley 1868:154, 116; Schouler 1868:420). The explosion of industry at Lowell had transformed the region from a sleepy agrarian backwater to a thriving industrial center.

Though the growth of Lowell is inexorably linked to the growth of the canals, their role of great importance after 1835 was tied to their ability to produce waterpower, not transportation. From the 1830s through the end of the century, the major driver of transportation became the railroad. The first railroad established in the region was the Boston-Lowell Railroad, opened in 1835 (Cowley 1868:78). The following year, a new charter was granted to extend the Boston-Lowell Railroad to Nashua, New Hampshire, accomplished in 1838 with the opening of the Nashua-Lowell Railroad (Gerstner & Gamst 1997:312–313). The Boston-Lowell Railroad received increasingly more connections, like the Boston-Portland (1839) and the Boston-Maine (1840) lines (Gerstner & Gamst 1997:315–316). Additional lines, like the Salem and Lowell Railroad, was established in 1848 (Cowley 1868:137). By the late 1830s, the railroads had become an important means of transportation in Lowell, as well as an economic opportunity. Lowell soon found itself involved in the production of steam locomotives. These locomotives became the workhorses of the Boston-Providence Railroad, among others (Gerstner & Gamst 1997:333–334). The coming of the railroads to Lowell increased the speed and reliability of trade and made the cost of shipping substantially cheaper than it had been via canal or road (Gerstner & Gamst 1997:312–304). Additionally, these rail lines enabled passengers to travel more quickly around New England. This transportation innovation spurred further economic growth and made distant markets more profitable by reducing the cost of freight (Gerstner & Gamst 1997:304). However, for the Middlesex Canal, the coming of the railroad spelled disaster. Unable to compete with the faster and cheaper trains, the canal was closed in 1860 (Mower 1991; Gerstner & Gamst 1997:294).

4.2.5 *Civil War to Twentieth Century*

The Civil War saw great upheaval in the United States, and the city of Lowell was no exception. Faced with a dwindling supply of cotton from the southern states, many mills in Lowell were forced to close down, displacing much of the work force (Lowell Historical Society 2005:8). Nevertheless, the citizens of Lowell rose to the occasion, supplying 5,266 men for service in the Union Army—more than had been asked of them (Schouler 1868:424). While the fighting men of New England were victorious in battle, the South would ultimately get its revenge. After the Civil War, the South began to invest in textile infrastructure, having realized during the conflict that their lack of manufacturing infrastructure had made them vulnerable (Minchin 2013:21–22). The South had a large pool of unskilled labor and ready access to cotton, and thus was able to cheaply produce textiles (Minchin 2013:21–22).

The late nineteenth century boom of textile manufacture in the American South started to undercut the northern textile industry, but the full effect of this industrial shift would not be felt until after the Great Depression (Minchin 2013:21–22). In the 1840–1850s, prior to the Civil War, Lowell saw a large wave of Irish immigrants arrive in search of work and join the small established Irish community within the city, which had existed since Kirk Boott had brought them over to dig the canals in the 1820–1830s (Dublin 1992:65–67). While there was already an established population of Irish workers at Lowell, this new wave of immigration greatly expanded their numbers. This expansion was followed by a wave of immigration from French Canada in the 1860s–1870s (Dublin 1992:67; Lowell Historical Society 2005:8). These new immigrants replaced the mill girls of the earlier part of the century, who had mostly returned home when the mills had been closed during the war (Dublin 1992:67). The heads of the mills believed that the only way they could compete with the emerging industry in the South was to employ cheap, unskilled immigrant labor. Cheap immigrant labor helped to keep down costs and enabled mill owners to remain profitable despite fluctuations in raw cotton supply (Dublin 1992:67). This shift in

mindset meant that immigrant labor would dominate Lowell's industrial workforce through the end of the century.

In the latter part of the nineteenth century and early twentieth century, additional waves of immigration from Eastern Europe and the Mediterranean brought additional workers to the mills in Lowell that had regained prosperity and continued to grow (Dublin 1992:68). These new immigrants created their own ethnic communities within the city, much as the Irish and French Canadians had previously done. By the dawn of the twentieth century, Lowell was an extremely multi-ethnic city, with Irish, French-Canadian, Polish, Greek, Portuguese, Hungarian, Jewish, and Lithuanian neighborhoods (Dublin 1992:68, 70–74; Lowell Historical Society 2005:8).

4.2.6 *Decline of the Textile Industry*

For most of the late nineteenth century, the northern mills continued to hold their own with their southern counterparts. However, in 1895, the strain began to show and the cotton industry in Lowell began to decline (Dublin 1992:82). The process was slow and did not come to a tipping point until the depression that followed World War I. After World War I, the textile industry collapsed, which was bad for all cotton manufactures—but in the South, access to cheaper material, more modern machinery, and non-union labor enabled them to persevere (Minchin 2013:22, 33; Dublin 1992:82). Mills all over New England could no longer compete and folded (Minchin 2013:21–22, 249–250). While some mills shuttered their doors as early as 1914, the worst came during the year of 1926, when Lowell's economy saw the closing of the Hamilton Company, the Suffolk Mill, the Tremont Mill, the Massachusetts Mill, and the relocation of the Appleton Mill and Saco-Lowell Shop (Dublin 1992:82). The impacts for Lowell were dire. Immigration came to a standstill and population declined. Mills all across the city closed as the cotton industry shriveled, so that by the mid-1930s, the cotton industry in Lowell had regressed to the size it had been just after the first mills in Lowell were established back in the 1830s (Dublin 1992:85). Those mills that remained—namely the Boott, Lawrence, and Merrimack Mills—were the last vestiges of the cotton industry in Lowell through the 1940s (Minchin 2013:249). Unemployment ran rampant and the city entered a long period of post-industrial decline (Dublin 1992:85). This was briefly curtailed by the outbreak of World War II and the demand for textiles and munitions that came with it, but the resurgence was short-lived; when the war ended, so too did the economic upturn (Dublin 1992:89). In the 1950s, the remaining Boott and Merrimack Mills finally closed, signaling the end of the textile industry in Lowell and contributing to further economic hardship (Dublin 1992:90).

4.2.7 *Late Twentieth Century*

Lowell struggled throughout the 1960s to find its economic footing, but it was not until the 1970s that the city began to recover. In 1974, the Lowell Heritage State Park was established, followed by the Lowell National Historic Park in 1978 (Dublin 1992:90; Lowell Historical Society 2005:8). The establishment of the University of Lowell in 1975 created new economic opportunities for the city, as did the arrival of Wang Laboratories, involved in the new computer industry (Dublin 1992:90). These events started Lowell on a path to recovery. Higher education and the technology industry proved the path to Lowell's salvation, as the city saw new investment in these industries continue through the 1980s and into the 1990s. The derelict buildings left by the abandonment of the milling industry were put to new use and occupied once more. As these new industries have grown, Lowell has once more begun to attract immigration. Lowell's modern immigrants come from Southeast Asia and Latin America, and like their predecessors at the dawn of the twentieth century, they have established ethnic neighborhoods of their own, enriching the cultural tapestry of the city (Dublin 1992:91; Lowell Historical Society 2005:8).

5.2 *Historic Architectural Resources*

5.2.1 *NRHP Properties in the APE*

Background research gathered from MACRIS, a MHC visit, and other online sources determined that there are four NRHP-listed resources in the APE. One of those resources, the Lowell Locks and Canals Historic District, is also a National Historic Landmark (NHL). An NHL is a nationally significant historic place designated by the Secretary of the Interior because it possesses exceptional value or quality in illustrating or interpreting the heritage of the United States (NPS 2014). See Table 3 below for more detailed information. For resource locations, see Appendix B.

Table 3 - NRHP-Listed Properties in the APE

NRHP Inventory #	MHC Inventory #	Name	Address	Built Date	Listing Date
76001972	LOW.C	Lowell Locks and Canals Historic District	Between Middlesex St and the Merrimack River	18th and 19th centuries	NRHP: 8/13/1976 NHL: 12/27/1977
78003149	LOW.BC	Lowell National Historic Park	Around Merrimack Street	18th and 19th centuries	6/5/1978
03000170	---	Lowell Historic Preservation District	Around Merrimack River	18th and 19th centuries	1/19/2001
72000117 09000939	LOW.CJ	Middlesex Canal and Archaeological District	Merrimack River (Lowell, MA) to Charles River (Boston, MA)	1803	8/21/1972 11/19/2009

The **Lowell Locks and Canals Historic District** is a 125-acre district that consists of 10 canals and their accompanying gates, locks, and dams; seven mill yards and ruins of another; the Locks and Canals yard; the Lowell Machine Shop; and several company boarding houses, plus the residence of a company agent. The district is significant for its association with the industrial history of the United States (Criterion A) and for its engineering merit (Criterion C). Its period of significance is 1821–1930 (Adams 1977). The APE passes through the district at two railroad bridge crossings: near the intersection of Dutton Avenue and Western Avenue, and a Warren truss bridge just east of Walker Street. Only the Warren truss bridge is over 50 years in age; the Boston Bridge Works constructed it in 1928. The nomination form does not mention the bridge or give any indication that it is a contributing or noncontributing resource to the district.

The **Lowell National Historic Park** was the first urban park established in the United States in 1978. The park, comprising many sites in Lowell, is dedicated to the rich textile history of Lowell and its larger role in the Industrial Revolution in America. The historic park was named an NHL in 1978, but wasn't documented until 1985. Subsequently, the North Atlantic Regional Office of the National Park Service (NPS) prepared a List of Classified Structures (LCS) indicating the contributing and noncontributing resources in the district. The APE passes through the historic park and crosses the Pawtucket Canal, which is a contributing resource to the district. The 1928 Warren truss bridge (in the APE) also falls in the historic park, but there is no indication that it is a contributing or noncontributing resource to the district.

The **Lowell Historic Preservation District** was created by the legislation establishing Lowell National Historic Park and includes more than 500 acres in the central historic and industrial center of the city. No

documentation was found during the research phase that indicates contributing and noncontributing resources have been identified. The district was not listed at all in the MACRIS database.

The **Middlesex Canal Historic and Archaeological District** begins in Lowell at the Merrimack River, just west of where it is intersected by Baldwin Street. From there, the district runs southeast to the Charles River in Boston. The district contains 225 individual contributing resources, 220 sites, and five buildings along its 27.25-mile route. The portion of the canal that falls within the APE is located in the northernmost portion (referred to as Segment 1 or L-1 in the nomination) of the district, but in this location, commercial and industrial development has covered over the canal. The 2009 NRHP nomination form indicates that a segment of canal and a basin may be located beneath the modern development, and that they are both significant contributing features of the district. No aboveground architectural resources associated with the canal exist within the project APE.

5.2.2 *Previously Surveyed Resources Not Evaluated for NRHP Eligibility*

Background research conducted via MACRIS and MHC also determined that there are seven historic architectural resources within the APE that have been previously surveyed and evaluated, but have not been determined eligible or ineligible by MHC or the NRHP. See Table 4 and the following paragraphs for more detailed information on those resources.

Table 4 Previously Surveyed Properties

MHC Inventory #	Name	Location	City	Built Date	Resource Type	Eligibility Recom.
CLM.917	Stony Brook Railroad Bridge	East of Middlesex St	Chelmsford	1850	Structure: Bridge	Eligible
CLM.920	Wotton Road - Deep Brook Railroad Bridge	Wotton Road	Chelmsford	1937	Structure: Bridge	Not Eligible
TYN.900	Tyngsborough Bridge	Middlesex Rd	Tyngsborough	1930	Structure: Bridge	Eligible
TYN.903	Mill Brook Railroad Bridge	Mill Brook	Tyngsborough	1928	Structure: Bridge	Not Eligible
TYN.904	Ferry Road Railroad Bridge	Ferry Road	Tyngsborough		Structure: Bridge	Unknown
TYN.912	Kendall Road Bridge over B & M Railroad	Kendall Rd	Tyngsborough	1930	Structure: Bridge	Potentially Eligible
TYN.922	Nashua & Lowell Railroad Cattle Tunnel	Farwell Rd	Tyngsborough	ca. 1838	Structure: Tunnel	Eligible

The **Stony Brook Railroad Bridge** (CLM.917) is an 84-foot-long stone double-arch bridge that carries the Nashua and Lowell Railroad/Boston and Maine Railroad over the mouth of Stony Brook at the Merrimack River in Chelmsford. According to the historic structure inventory form completed for a Phase II MBTA historical property survey in 1988, the bridge is the only intact stone-arch bridge on the line (Stott 1988). In the inventory form, the bridge was recommended eligible for listing in the NRHP.

The **Wotton Road - Deep Brook Railroad Bridge** (CLM.920) is a 16-foot-long steel I-beam stringer bridge with ashlar stone abutments that carries the Nashua and Lowell Railroad/Boston and Maine Railroad over Deep Brook in Chelmsford. It was built in 1937. According to the historic structure inventory form completed for a Phase II MBTA historical property survey in 1987, “the bridge is an example of a common type of twentieth century bridge construction and does not possess enough historic or engineering significance to merit further research or documentation” (Scott 1987a). As a result, it was recommended not eligible.

The **Tyngsborough Bridge** (TYN.900) is a 656-foot-long steel rib arch bridge that carries Sherburne Avenue over the railroad line and the Merrimack River. It was constructed in 1930. According to the historic bridge inventory form completed in 1991, it is a landmark bridge and a well-preserved example of a very uncommon type. It is the second oldest of five identified steel rib through arch bridges recorded in a historic bridge database created by the Massachusetts Department of Public Works (Roper 1991). As a result, it was recommended potentially eligible.

The **Mill Brook Railroad Bridge** (TYN.903) is a 17-foot-long reinforced concrete slab bridge with stone abutments and ballasted deck that carries the Nashua and Lowell Railroad/Boston and Maine Railroad over Mill Brook in Tyngsborough. The bridge was constructed in 1928. According to the historic bridge inventory form completed in 1987, "the bridge is an example of a common type of twentieth century bridge construction and does not possess enough historic or engineering significance to merit further research or documentation" (Scott 1987b). As a result, it was recommended not eligible.

The **Ferry Road Railroad Bridge** (TYN.904) is located approximately 225 feet north of the Tyngsborough Bridge. The inventory form for this resource was not found during the records search at MHC; therefore, construction date and details are unknown.
The **Kendall Road Bridge** (TYN.912) is a 67-foot-long single-span steel I-beam stringer with a concrete deck. The bridge was constructed in 1930. The Masshighway historic bridge inventory form completed in 1997 indicates that the Kendall Road Bridge is essentially an approach to the Tyngsborough Bridge, and is an integral part of the landmark steel rib through arch bridge (Roper 1997). As a result, it was recommended potentially eligible.

The **Nashua and Lowell Railroad Cattle Tunnel** (TYN.912) is a granite stone constructed tunnel that passes under the railroad to enable cattle to have access to pasture on both sides of the ROW. An MHC Form F (for structures) was completed in June 2002 and indicates that the tunnel was constructed by the railroad in or around the time the line was built in 1838 (Johnson 2002). It was recommended eligible for listing in the NRHP.

5.2.3 *Resources Not Previously Surveyed in the APE*

Prior to and following the site visit, additional online research was conducted to identify any architectural resources over 50 years in age within the APE that were not previously surveyed or documented. The most informative sources were historic and current aerial images available on Historic Aerials (www.historicaerials.com), Google Earth, and Bing Maps. The Historic Aerials website maintains images of Lowell from 1938, 1963, 1965, 1971, 1978, 1995, and 2005; Chelmsford from 1963, 1965, 1971, 1978, 1995, and 2005; and Tyngsborough from 1938, 1963, 1965, 1971, 1978, 1995, 2001, 2003, and 2005. Google Earth maintains aerial images from the 1990s, 2000s, and 2010s. By reviewing aerial images from the 1950s–60s and comparing them with current images, it was possible to locate buildings that may be over 50 years in age within the APE. Photographs available via Google Earth Street View and Bing's Bird's-Eye-View provided an initial view of the buildings in the project area that aided with identification in the field.

Background research and the field visit determined that there are two previously unidentified properties that may be over 50 years in age or older within the direct APE. By virtue of their age, properties that are over 50 years old are considered potentially eligible for listing in the NRHP and have the potential to be effected during the undertaking. The two resources include a railroad line and a railroad bridge. The railroad line itself, part of the Nashua and Lowell Railroad/Boston and Maine Railroad, passes through the entire APE. See Table 5 below for a list of properties over 50 years in age that have not been previously surveyed.

Table 5 - Resources Not Previously Surveyed in the APE

Name/Address	Block/Lot	City	Resource Type	Built Date
Nashua and Lowell Railroad/Boston & Maine Railroad	----	ALL	Railroad line	c. 1838
Warren Truss Railroad Bridge over Pawtucket Canal	Between Walker St and Dulton Ave	Lowell	Warren Truss Bridge	1928

The **Nashua and Lowell Railroad** opened in 1838 as a continuation north of the Boston and Lowell Railroad. The initial track was laid on granite and, later, a second track was added with a wood base. In 1887, the **Boston and Maine Railroad** took over the entire line. The line and associated features have been altered over the years; currently the line has been reduced to one track (serving freight), and most of the stations and associated buildings (train sheds, water towers, flag houses, etc.) have been demolished. Within the APE, the only structures that appear to be part of the railroad line are tracks and bridges; no additional buildings or facilities appear to be within the ROW.

The **Warren Truss Railroad Bridge** is a steel Warren truss bridge constructed in 1928 by the Boston Bridge Works. It is a double-track railroad bridge that extends approximately 180 feet across the Pawtucket Canal. The bridge falls within the direct APE for the project.

6.0 Conclusions and Recommendations

6.1 *Archaeological Resources*

The literature review for the Capitol Corridor Rail Transit Study project revealed that the Massachusetts portion of the project, termed the Lowell Study Area, had a high probability for encountering both historic and prehistoric cultural resources. This determination was based upon the analysis of previously recorded archaeological sites, historical documentary research, and historic maps. The assessment of sensitivity largely concentrates on the potential of the soil to contain cultural resources. The designation of archaeological potential or sensitivity only takes into account the presence, or likely presence, of archaeological resources within the study area; it does not include other factors, like the impact of disturbance or the archaeological integrity of the sites used in the analysis. Therefore, an area classified as high probability might contain no resources due to past ground-disturbing activities, stripping, or grading. Additionally, the nature of the proposed project may negate the need for archaeological investigation if no ground disturbance is to occur. Bearing all this in mind, URS recommends that no further archaeological reconnaissance is necessary prior to the construction of the proposed track modifications, as no ground disturbance will occur. The Capitol Corridor Rail Transit Project proposes the construction of a secondary rail line paralleling the existing main rail line running between Lowell, Massachusetts, and Nashua, New Hampshire. This secondary rail line existed up until the mid-1960s, when decreasing demand for commuter rail service (due in large part to the postwar boom of the auto industry) led to the decommissioning of the secondary track, which was subsequently removed. However, the rail bed upon which that secondary track ran remains to this day, and can easily accommodate new track without requiring ground-disturbing activities. New track can be laid upon the existing bed, which has already been graded, compacted, and leveled, and is at present capping any soils left intact after these activities were completed in the first half of the nineteenth century (Wallace 2001). The presence of fill soils or redeposited strata does not necessarily negate the possibility of intact cultural deposits existing beneath. Filling episodes often act as caps, protecting underlying natural strata, even in urban areas (Marlatt et al. 2006:13). While it is possible that there are surviving cultural resources beneath the extant railroad bed, in the case of the proposed project, the extant rail bed is not being impacted, and thus, any potential resources lying beneath it will similarly remain free of disturbance. Therefore, since no soil is being disturbed, there is no potential adverse effect and no need for additional survey.

While the archaeological sensitivity of the Lowell Study Area may seem irrelevant given the scope of the proposed work, this is not the case. In the event that any additional rail bed needs to be constructed, moved, or altered during the course of the project, the archaeological potential of the study corridor would immediately become relevant. Any activity associated with the construction effort—including, but not limited to, the establishment of access roads, removal of existing railroad bed or other soil caps, or the establishment of new sections of rail bed—will need to be monitored by qualified archaeologists or subjected to an intensive Phase IB field survey prior to commencement of the work to ensure that there are no cultural resources present that might be adversely affected. Additionally, the placement of any support/maintenance facilities or construction staging areas will require Phase IB testing prior to their construction or usage to ensure that no cultural resources are negatively impacted.

6.2 *Historic Architectural Resources*

The NHDOT proposes to build station and layover facilities and make track improvements to the existing railroad corridor between Lowell, Massachusetts, and Concord, New Hampshire, as part of an effort to establish new commuter service. In Massachusetts, improvements would only consist of an additional

second track in the existing ROW in certain areas along the alignment. Historically, as noted above, this line contained a double track, but sometime in the twentieth century, the second track was abandoned.

Since the project would be limited to the existing ROW and would only consist of replacing a second track that existed historically, there is very little possibility for physical impacts and no possibility for visual impacts. As a result, no additional work is recommended.

APPENDIX A

8.0 Project Notification Form

APPENDIX A
MASSACHUSETTS HISTORICAL COMMISSION
220 MORRISSEY BOULEVARD
BOSTON, MASS. 02125
617-727-8470, FAX: 617-727-5128

PROJECT NOTIFICATION FORM

Project Name: New Hampshire Capitol Corridor Rail and Transit Study

Location / Address: (will follow the existing New Hampshire Main Line)

City / Town: Lowell, Tyngsborough, and Chelmsford - Middlesex County

Project Proponent

Name: New Hampshire Department of Transportation

Address: John O. Morton Building, 7 Hazen Drive, P.O. Box 483

City/Town/Zip/Telephone: Concord, New Hampshire 03302-0483 (603) 271-3734

Agency license or funding for the project (list all licenses, permits, approvals, grants or other entitlements being sought from state and federal agencies).

Agency Name	Type of License or funding (specify)
Federal Railroad Administration	
Federal Transit Administration	

Project Description (narrative):

See Section 1.1 in the Phase IA Cultural Resources Investigation report

Does the project include demolition? If so, specify nature of demolition and describe the building(s) which are proposed for demolition.

No demolition is proposed.

Does the project include rehabilitation of any existing buildings? If so, specify nature of rehabilitation and describe the building(s) which are proposed for rehabilitation.

No rehabilitation is proposed.

Does the project include new construction? If so, describe (attach plans and elevations if necessary).

Proposed work will only consist of the addition of a second railroad track within the existing right-of-way. The locations are depicted in mapping included in Appendix A of the aforementioned report.

To the best of your knowledge, are any historic or archaeological properties known to exist within the project's area of potential impact? If so, specify.

See attachment

What is the total acreage of the project area?

Woodland	acres	Productive Resources:	
Wetland	acres	Agriculture	acres
Floodplain	acres	Forestry	acres
Open space	acres	Mining/Extraction	acres
Developed	acres	Total Project Acreage	acres

What is the acreage of the proposed new construction? _____ acres

What is the present land use of the project area?

Railroad-related and industrial use.

Please attach a copy of the section of the USGS quadrangle map which clearly marks the project location.

This Project Notification Form has been submitted to the MHC in compliance with 950 CMR 71.00.

Signature of the person completing this form

Date

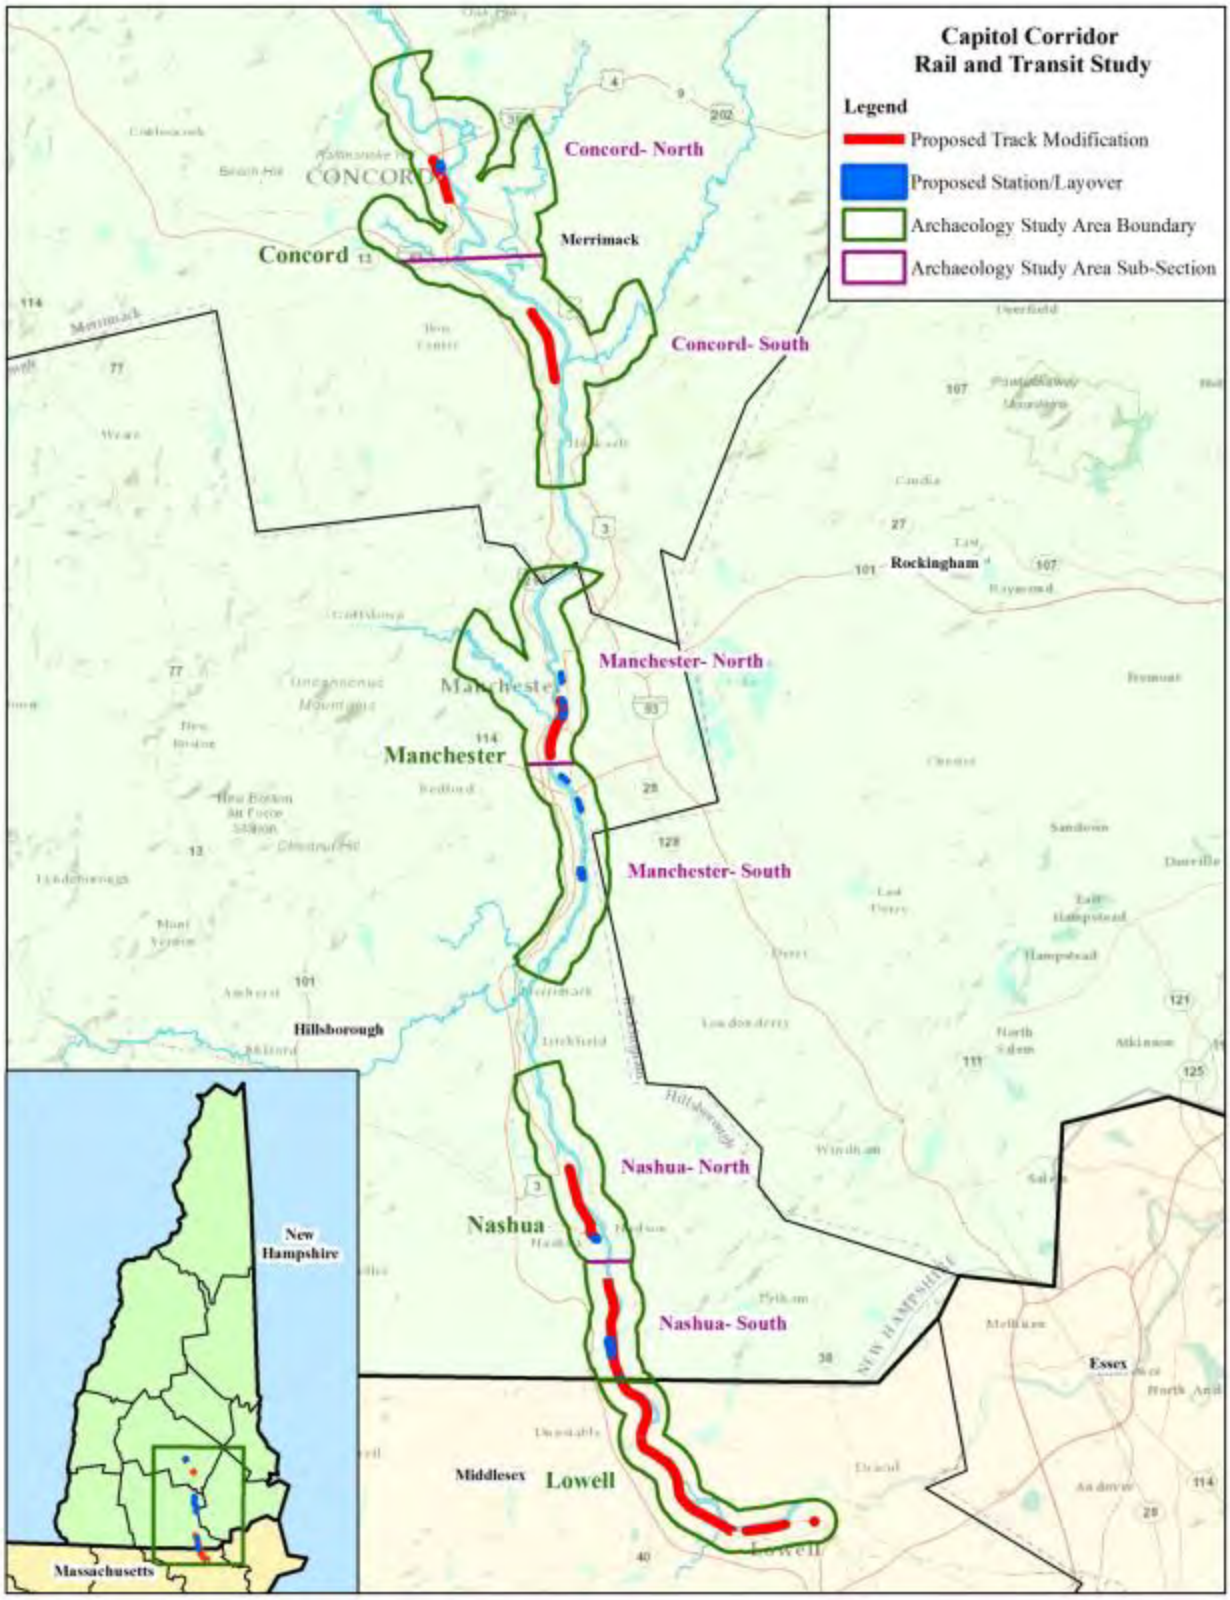
Name: Vanessa Zeoli

Address: 437 High Street

City/Town/Zip: Burlington, NH 08016-4514 Phone: 609-386-5444

For supplemental information required as part of the Project Notification Form (including the Project Boundaries and Description, USGS map, architectural background information, and archaeological background information), please see the attached Phase IA Cultural Resources Investigation

9.0 Resource Location Map



Project overview map showing station locations, track modifications and archaeological study areas.

APPENDIX E

10.0 Professional Qualifications

URS

Andrew Wyatt

Senior Archaeologist

Area of Expertise

- Archaeology of Historic
- And Prehistoric Native Americans
- Section 106 of the National Historic Preservation Act
- Archaeological Surveys and Excavations
- Lithic and Ceramic Analysis
- Geomorphology
- Technical Report Production
- Historic Contexts
- Public Involvement

Years of Experience

With URS: 2
With Other Firms: 24

Education

M.A./2007/Temple University/Anthropology

B.A./1988/State University of New York at Albany/Anthropology & Mediterranean Archaeology

Continuing Education

- SRI Foundation- Section 106 Principles and Practice, February 2003

Overview

Mr. Wyatt has 26 years of experience in archaeological investigations and Section 106 of the National Historic Preservation Act in the Middle Atlantic and northeastern United States. Andrew possesses a strong background in archaeological field and laboratory methods along with extensive training and experience in lithic and ceramic analysis and geomorphology. His primary specialization is the study of Native American groups through archaeology and ethnohistory. Although the majority of his work has been focused in Pennsylvania, he been has directed field surveys, artifact analysis, and written technical reports for projects in Delaware, New York, Maryland, Ohio, and Virginia. His current responsibilities include project management, project scoping, proposal, workplan, and technical report preparation. Mr. Wyatt worked at the Pennsylvania State Historic Preservation Office as an archaeological reviewer, gaining a comprehensive understanding of agency coordination under Section 106 as well as the cultural resource management needs and responsibilities of federal and state agencies, private entities, and the public. He is the author or co-author of more than 70 technical reports, 25 professional papers, several peer-reviewed publications, as well as numerous presentations and materials for the general public.

Select Project Experience

Phase IB Archaeological Investigation, Northeast Pocono Reliability Project, PPL Electric Utilities, Northeastern PA: Co-Principal Investigator for a 64-mile electric transmission line right of way and two 100+ acre substations. Tasks include logistical coordination of staff, supervision of fieldwork, report preparation, and SHPO consultation. Identified nine historic Euro-American sites and one Native American archaeological site. Worked with client to avoid those which were potentially eligible for listing on the National Register of Historic Places (NRHP).

Phase I Archaeological Investigation, Clarion Area Wastewater System Upgrade, Pennsylvania-American Water Company, Clarion and Strattanville Boroughs, Clarion and Monroe Townships, Clarion County, PA: Principal Investigator, report author for identification-level survey of eight miles of collection line and wastewater treatment plant upgrade.

Phase IB Archaeological Archaeological Investigation, Rochester Area Reliability Project, Rochester Gas & Electric, Monroe County, NY. Principal Investigator for a 24-mile electric transmission line right of way. Tasks include SHPO consultation, logistical coordination of staff, supervision of fieldwork, and report preparation. Identified two historic Euro-American sites and three

Native American archaeological sites. Worked with client to avoid those which were potentially eligible for listing on the National Register of Historic Places (NRHP).

Phase I Archaeological Archaeological Investigation, MF-42 Gas Line Replacement Project, Rochester Gas & Electric, Monroe County, NY: Principal Investigator for a 1.5 mile natural gas line replacement. Tasks included SHPO consultation, development of costs and scope, logistical coordination of staff, supervision of fieldwork, report preparation. Assisted client by performing investigation within an expedited construction schedule.

Phase I Archaeological Investigations, Cabot Oil and Gas Company, Meshoppen Creek Impoundment, Lemon Township, Wyoming County, PA: Principal Investigator for identification-level survey of a proposed 30-acre freshwater impoundment. Tasks include development of costs and scope, logistical coordination of staff, supervision of fieldwork, report preparation, and SHPO consultation.

Phase I and Limited Phase II Archaeological Investigations, Angelina Gathering Company, N Gathering Line Modifications, Stevens Township, Bradford County, PA: Prinicipal Investigator for identification-level survey and archaeological site boundary definition within natural gas pipeline corridor. Assisted client in avoiding a potentially NRHP-eligible archaeological site within an expedited construction schedule through close coordination with SHPO.

Phase I Archaeological Surveys, Marcellus Shale Gas Development Projects, Williams Field Services Company, Angelina Gathering Company, CONE Gathering, LLC, SWEPI, Northeastern and Western, PA: Served as Principal Investigator for multiple Phase I identification-level surveys in northcentral Pennsylvania. Tasks include development of costs and scope, logistical coordination of staff, supervision of fieldwork, report preparation and SHPO coordination. Projects are ongoing and accomplished under fast-paced timelines for fieldwork and reporting.

Phase I Archaeological Surveys, Marcellus Shale Gas Development Projects, Talisman Energy USA, Bradford, Tioga, and Susquehanna Counties, PA: Served as Principal Investigator, author or co-author of technical reports for Phase I identification-level surveys in north central Pennsylvania.

Phase I/II/III Archaeological Studies at the Lemoyne Site, Norfolk Southern Railway Company, Borough of Lemoyne, and the National Park Service, Cumberland County, PA: Principal Investigator and Field Director for identification, excavation and analysis of an early 17th century A.D. Susquehannock village. Primary technical report author for all phases of investigation and coordinator of an interdisciplinary team of faunal and paleobotanical specialists for Phase III mitigation studies. This project was conducted in advance of new rail line construction by Norfolk Southern on park property owned by the Borough of Lemoyne, with Section 106 oversight by the National Park Service. The investigation resulted in a new perspective on Susquehannock village relocation, chronology, and agricultural practices. Mr. Wyatt also directed public involvement efforts which included site tours, presentations geared toward all ages, and a published booklet explaining the site's importance.

Phase I/II/III Archaeological Studies, S.R. 0056 Transportation Improvement Project, PennDOT and FHWA, Bedford County, PA
Report co-author, primary artifact analyst for three prehistoric Native American quarry-related sites. Developed research strategy and coordinated the work of geologists to chemically characterize local cherts.

Phase II/III Archaeological Studies, PennDOT and FHWA, Schantz Road Realignment, Lehigh County, PA: Principal Investigator and Field Director of Phase III fieldwork on an early Federal period Pennsylvania German farmstead that also contained significant prehistoric Native American occupations.

Managed in-house artifact analysis as well as multidisciplinary team of paleobotanical and lithic use-wear specialists.

Phase III Archaeological Studies, PennDOT and FHWA, Route 309 Connector Project, Bucks & Montgomery Counties, PA: . Primary report author and artifact analyst for Phase III mitigation of a prehistoric Native American site with a strong Late Woodland component. Managed an interdisciplinary team of paleobotanical, lithic use-wear, and protein residue specialists to interpret a short-term ancestral Lenape campsite. Co-produced a booklet for the public detailing archaeological investigations done for the transportation project and its importance for understanding Lenape prehistory.

Phase III Archaeological Studies, PennDOT and FHWA, SR 147 Climbing Lane, Northumberland County, PA: Co-Principal Investigator, primary artifact analyst and technical report author for Phase III mitigation of stratified, multicomponent Native American site on the Susquehanna River floodplain. Managed an interdisciplinary team of pedological, paleobotanical, lithic use-wear, and protein residue analysts. This investigation uncovered rarely-seen evidence for hunter-gatherer storage behavior circa 3500 B.C., and prompted a re-evaluation of Late Archaic settlement patterns in the central Susquehanna River drainage. Project results were widely disseminated through professional papers and presentations for local residents.

Selected Professional Papers and Presentations

Wyatt, Andrew

2012 "Reconsidering Susquehannock Settlement Patterns, Excavations at the Lemoyne Site, Cumberland County, Pennsylvania." Paper presented at the Pennsylvania Archaeological Council Symposium "Recent Research on the Susquehannocks" as part of the 83rd Annual Meeting of the Society for Pennsylvania Archaeology, Clarion, Pennsylvania.

Andrew Wyatt and Barbara J. Shaffer

2010 "Small is Beautiful: Data Recovery Excavations at a Multi-Component Native American Campsite in Montgomery County, Pennsylvania." Poster presented at the 90th Annual Meeting of the Transportation Research Board, Washington, D.C.

Wyatt, Andrew

2009 "Early Seventeenth Century Susquehannock Settlement Patterns Reconsidered: Results from the Lemoyne Borough Memorial Park Site, Cumberland County, Pennsylvania." Paper presented at the 76th Annual Meeting of the Eastern States Archaeological Federation, Johnstown, Pennsylvania.

Wyatt, Andrew

2009 "Final Excavation Results from the Lemoyne Borough Memorial Park Site (36Cu194): A Washington Boro Stage Susquehannock Site in Cumberland County, Pennsylvania." Paper presented at the 80th Annual Meeting of the Society for Pennsylvania Archaeology, Harrisburg, Pennsylvania.

Wyatt, Andrew

2008 "Preliminary Excavation Results from the Lemoyne Borough Memorial Park Site (36Cu194): A Washington Boro Stage Susquehannock Site in Cumberland County, Pennsylvania." Paper presented at the Statewide Conference on Heritage, Harrisburg, Pennsylvania.

Andrew Wyatt, Barbara J. Shaffer, and Joseph S. Hollinger

2008 "Norfolk Southern Rail Connector Project, Lemoyne Borough, Cumberland County, Pennsylvania." Poster presented at the 87th Annual Meeting of the Transportation Research Board, Washington, D.C.

Burns, Jonathan A. and Andrew Wyatt
2007 "Rockshelters as Persistent Places: The View from Camelback." Paper presented at the 78th Annual Meeting of the Society for Pennsylvania Archaeology, Allentown, Pennsylvania.

Andrew Wyatt and Robert Eiswert
2006 "Late Archaic Occupation at the Raker I Site, Northumberland County, Pennsylvania: Implications for Settlement Models in the Central Susquehanna Drainage." Paper presented at the 77th Annual Meeting of the Society for Pennsylvania Archaeology, Washington, Pennsylvania.

Andrew Wyatt and Barbara J. Shaffer
2006 "Archaeological Investigations at the Raker I Site: A Stratified Late Archaic and Late Woodland Site Along the Susquehanna River, Northumberland County, Pennsylvania." Poster presented at the 85th Annual Meeting of the Transportation Research Board, Washington, D.C.

Wyatt, Andrew
2005 "Late Archaic Occupation at the Raker I Site, Northumberland County, Pennsylvania." Paper presented to the Northumberland County Historical Society, Sunbury,Pennsylvania.

Wyatt, Andrew
2004 "Water From A Deeper Well: An Analysis of Final Cordage Twist Direction on Woodland Pottery from the Central and Northern Susquehanna Drainage." Paper presented at the75th Annual Meeting of the Society for Pennsylvania, Clarion, Pennsylvania

Wyatt, Andrew, Francine Arnold, and Barbara Shaffer
2003 "Prehistoric Lithic Reduction Sequencing and Historic Farm Life at the Snook Farm Site (36BD217) and other Sites in Bedford County." Paper presented at the74th Annual Meeting of the Society for Pennsylvania, State College, Pennsylvania

Wyatt, Andrew
2002 "Prehistoric Lithic Workshop Sites on Chestnut Ridge in Bedford County, Pennsylvania." Paper presented at the73rd Annual Meeting of the Society for Pennsylvania, Greensburg, Pennsylvania

Wyatt, Andrew

Mr. Dworsky joined URS Corporation in 2012 and has 9 years of experience in archaeology and cultural resources management. He has participated in the excavation of sites throughout the Mid-Atlantic Region, and Bermuda. He has previously served as the field and laboratory foreman/manager for Millersville University and oversaw the numerous Phase I, Phase II, and Phase III surveys. At Millersville University he constructed artifact databases, websites, oversaw artifact preservation and cleaning, and instructed student in field techniques and the fine points of field excavation. He also headed up the background research effort for that university conducting research throughout the tri-state area, Bermuda, the UK and Caribbean. As an archaeologist at URS, his responsibilities include fieldwork, in addition to his duties as a GIS specialist wherein he prepares maps, collects GPS data, manages the GIS databases of several projects and insures the accurate integration of field and laboratory data into a cohesive and comprehensive GIS database. Mr. Dworsky is the co-author of several technical reports and professional papers, and his experience encompasses historic and industrial archaeological investigations as well as human osteology.

Project Specific Experience

URS Corporation

Pennsylvania Turnpike Commission - Phase Ib Archaeological Survey for the PTC Turnpike Total Milepost 312 To 31. Co-authored and prepared the addendum report to the initial Phase Ib archaeological assessment which included the identification analysis of two sites in Chester County, PA, one prehistoric and the other a 19th century historic site.

Sunbury Transmission Line Project, Sunbury, Pennsylvania. GIS Analyst. Designed and help to implement a hovel testing strategy for the 33 miles of pipeline ROW that comprise the project APE. Managed and updated the GIS with data coming in from the field and generated new route recommendations based on that data. FERC compelled the section 106 survey of this area in advance of the construction of a gas pipeline proposed by UGI Company. The survey uncovered many prehistoric and historic sites many of which are awaiting Phase II investigation.

Bartram's Garden Monitoring Project. Graduate Archaeologist, Field Archaeologist, GIS analyst. Oversaw the mechanical stripping of areas adjacent to a known prehistoric site along the Schuylkill River in Philadelphia, PA. Discovered new components to the known site. Excavated, mapped and reported new findings in a report addendum.

Constitution Pipeline Project, New York and Pennsylvania. Field archaeologist and GIS specialist for the Phase I survey of a more than 200 mile stretch of northern PA and central NY. FERC conducted the Section 106 survey of this area in advance of the construction of a gas pipeline proposed by Williams Gas Company. The survey uncovered many prehistoric and historic sites many of which are awaiting Phase II investigation.

General Electric Hudson River Project, Fort Edward, New York. Field archaeologist and GIS specialist for the Phase I survey of the Hudson River in the advance of dredging by General Electric. This shore survey was conducted to insure no sites were adversely affected by potential slumping of the riverbank if undermined by dredging activity in the river channel. In addition to the Phase I work, a Phase II study was conducted at Fort Miller, a French and Indian War era fort, located near Lock 5 on the Hudson River. This site was first investigated during the Phase I survey and received further testing because of a proposed processing plant for the decontamination of dredged soils. This Phase II investigation revealed the remains of the builder's trench and posts that comprised two palisade walls, as well as several pit features that contained military artifacts, burnt timbers, and period ceramics. This site is of importance because it was a small provisioning fort for the larger forts upstream and no fort of its kind from this period has been studied. At the present it is unknown if the client will push for a Phase III data collection.

Archaeological Investigations of the I-95/Girard Ave. Improvements Project, Philadelphia, Pennsylvania. GIS Specialist. Study conducted for the Pennsylvania Department of Transportation, Engineering District 6-0. Created GIS generated maps of the ongoing Phase IB, II, and III archaeological investigations along a three-mile long portion of the Interstate 95 highway corridor. Responsibilities include creating maps for a variety of discovered sites, including portions of the former Aramingo Canal prism, the Dyottville Glass Works, multiple 18th and 19th century domestic historic sites, as well as a prehistoric Native American encampment.

Richard Grubb and Associates

Archaeological Investigations at French Town, New Jersey. Field Technician. The work was done for the ACOE and preceded the expansion of an existing sewage treatment plant adjacent to the Delaware River. This Phase II investigation consisted of two deep 2x2 meter test units in deep flood plain soil terminating nearly 2 meter below ground surface. One test unit revealed evidence of Early Archaic occupations in one of the deepest buried "A" horizons.

College of William and Mary

Archaeological Investigations at Whitehall/The John Trimmingham Site, St. Georges, Bermuda. Field Foreman/Teaching Assistant. Performed for the Bermuda National Trust, National Museum of Bermuda, and the St. George Foundation. The work was done as a Phase II investigation of some foundation deposits discovered during the resurfacing of a road in the historic downtown district of St. Georges. The subsequent Phase II testing project undertaken by the College of William and Mary revealed a partial foundation dating to the 17th century. Documentary research revealed the owner of the parcel as one John Trimmingham, a prominent member of colonial St. Georges. One of the most interesting discoveries was two fully articulated bovine carcasses that had been buried beneath a collapsed wall of the house. It turns out that these bovine had suffered from hoof and mouth and were unceremoniously slaughtered and the walls of a ruin push on top of them. This is the only know instance of a livestock burial ever found on the island.

Millersville University

Millersville University Atlantic World Project, Southampton Parish, Bermuda. Field foreman, research director, lab director. This work was done for the National Museum of Bermuda and the Bermuda National Trust as well as the DuPont Foundation. The project consisted of the Phase I & II survey of Dickinson Store site (c. 1730-1800), SN Bermuda, the Phase I survey of the Rectory site (c. 1760-present), SN, Bermuda and the Phase I survey of the Perot Site, Bermuda. The purpose of this project was to examine the homes and store houses of Bermudian merchants known to have ties with Philadelphia merchants. The goal was to seek out evidence of smuggled non-English materials at these sites and/or material links back to Philadelphia. This was part of a larger effort to examine colonial Atlantic trade both legal and illicit from all its aspects including: the nodes of production, distribution and terminal markets. These studies focused on the those nodes of distribution, namely merchant warehouses or slave quarters (enslaved mariners often carried on their own trade in illegal port, and their trade goods like plates, buttons, and bottles, tend to survive better archaeologically than the more perishable goods of their masters, i.e. sugar, flour, rum.) Archaeological evidence was provided for illicit trade with French and Spanish Caribbean possessions that previously was merely a matter of historical footnotes and not wholly quantifiable, these took the form of several types of French faience and Dutch wares, and glass that had no legal avenue into a British possession, save thorough privateering. These findings corroborated the documentary accounts of Bermudian recorded by various government officials both Bermudian and foreign. This research filled a glaring gap in the archaeology of 18th century transatlantic trade, and laid the groundwork for a subsequent Phase II research project.

Millersville University Lancaster Colonial Settlement Project, Lancaster PA. Field Foreman, Instructor, Lab Director. This was done on behalf of Millersville University and the DuPont Foundation. The purpose of this project was to demonstrate the importance of Lancaster County, PA as a culture hearth for the western settlement of the nation. To that end a variety of sites were investigated to illuminate the settlement history of Lancaster County. A series of three locations underwent Phase I survey.

The Mylin Gun shop, the alleged birth place of the Pennsylvania Long Rifle and the homestead of one of Lancaster original settlers, was the initial focus of the project. This survey tested the area surrounding a small building currently hailed as the Mylin gun shop. The survey demonstrated that despite the popular perception, the building was in reality an 18th century blacksmith shop and was not used for gunsmithing. The original homestead of Martin Mylin, the long rifles alleged creator and one of the first settlers in Lancaster, was not discovered during survey.

The second Phase I survey area covered a series of private farms and a Boy Scout camp located upstream of the confluence of the Big and Little Conestoga Rivers. This was the supposed location of James Logan trading post (Logan was William Penn's principal Indian agent). The survey revealed several areas of historic activity but nothing dating to that early 17th century period. The search zone was narrowed to just a few small acres, but due to lack of landowner permission the project proceeded no further.

The final location for Phase I survey, Elizabeth Furnace Iron Plantation, proved to be the most rewarding of the three Phase I surveys. The survey revealed the presence of more than 13 standing early and mid-18th century structures as well as a variety of subsurface features including a furnace race. This furnace race adjacent to the Huber House, c. 1742, became the focus of a Phase II and Phase III investigation which yielded a variety of sealed 18th century strata. The artifacts recovered during the Phase III data collection enabled the discussion of enculturation in the mid-18th century display a shift in immigrant identity from a mostly Germanic identity to a more Anglicized outlook, which was accompanied by a corresponding shift in the preference of material goods.

Subsequent Phase II & Phase III testing of a barracks and adjoining summer kitchen revealed a massive bone midden which housed the remains of the meals from the 75 Hessian prisoners of war that were housed and

worked at the furnace after the battle of Trenton. This bone midden revealed the use of primarily communal/yeoman food ways (i.e. Stews, soups) and a mixed diet including all kind of meat from pig, cow, horse, and deer to poultry.

A Phase III investigation and GPR survey or the core grounds of Elizabeth Furnace Plantation revealed the existence of the remains of the 18th century blast furnace, its casting house floor and a subsurface stone arched furnace tail race. The Phase III investigation of the industrial core of Elizabeth Furnace provided insight into the production capacity and scale of industry of this particular iron furnace, and prompted the documentary investigation of its markets and investors. Both the documentary research and archaeological findings suggested that the furnace was producing for a foreign as well as domestic market. The search to understand the scope of this trade network led to Bermuda and the founding of the Millersville Atlantic World Project (See Above)

Overview

Ms. Zeoli joined URS in July 2013 and has 13 years of experience in historic preservation and cultural resources management throughout the United States. In her position as architectural historian, she has acted as cultural resource liaison between various clients and local, state, and federal review agencies. Ms. Zeoli has completed numerous documentation and regulatory compliance projects including Section 106 studies (including eligibility evaluations, effects assessments, MOAs), NEPA studies (EAs and EISs), historic architectural surveys, HABS/HAER documentation projects, National Register nominations, historic preservation design consultation, and Historic Tax Credit Applications. She has surveyed and evaluated historic properties, evaluated eligibility in accordance with National Register criteria, evaluated project effects, and developed agreement documents to resolve adverse effects. Ms. Zeoli has worked with a wide range of resources in varying settings that include: transportation resources (historic roads, bridges, railroads, and airports); industrial properties (mills, breweries, manufacturing plants); institutional buildings (museums, churches, auditoriums); agricultural properties (farmsteads, tenant houses, cemeteries, rural landscapes); and urban buildings (residential and commercial historic districts). She meets the Secretary of the Interior's Professional Qualification Standards for Architectural Historians [36 CFR 61].

Project Specific Experience

Natural Gas Pipeline Projects in Pennsylvania and New York: Architectural Historian. Prepared eight Section 106 studies for proposed pipeline projects throughout northern Pennsylvania and south and central New York in 2013 and 2014. Work included background research, architectural surveys, inventory forms, eligibility assessments, effects determinations, and coordination with the PA and NY SHPO.

Rochester Gas & Electric Corporation: Russell Station Demolition Project, Greece, New York: Architectural Historian and Principal Investigator. A Historic Resource Inventory Form documenting the history and construction chronology, as well as assessing the significance, integrity and eligibility of the resource. Work included primary and secondary research and intensive-level survey. The station was recommended "Not Eligible" and the NYSHPO concurred in November 2013.

Scotch Plains Baptist Church, Parsonage, and Cemetery National Register Nomination, Scotch Plains, New Jersey: Senior Architectural Historian and Principal Investigator. The NRHP nomination was completed as part of a mitigation effort for alterations to the Route 22 bridge in Scotch Plains Township. The work included

primary and secondary research, field investigations, and completion of the NRHP nomination form. The property was listed in the National Register of Historic Places on June 14, 2013.

Chicago Transit Authority (CTA), Wilson Transfer Station Rehabilitation Project, City of Chicago, Illinois: Senior Architectural Historian. Project involved Section 106 compliance for rehabilitation of the historic Wilson Station and reconstruction of 1,200 feet of elevated rail line within the National Register-listed Uptown Square Historic District. The work included an architectural survey, eligibility evaluations, effects assessments, consulting party coordination, and preparation of a Memorandum of Agreement.

Historic Architectural Effects Assessment Report, Potomac Yard Metrorail Station, City of Alexandria, Virginia: Senior Architectural Historian. Project consists of construction of a new Metrorail station adjacent to the National Register-listed George Washington Memorial Parkway. The work consisted of Section 106 and NEPA studies in support of an Environmental Impact Statement. The project also involved extensive consultation efforts with the Virginia Department of Historic Resources, the National Park Service, and other consulting parties.

California High-Speed Train Project, California High-Speed Rail Authority (CAHSRA), Merced to Fresno, California: Architectural History Task Leader. Project involved the preparation of an Environmental Impact Report/Environmental Impact Statement for the design and construction of a high-speed passenger train system for a 60 mile section between Merced and Fresno. Compliance efforts under Section 106 and NEPA involved conducting background research, conducting field survey, compiling data, eligibility evaluations, effects assessments, developing treatment measures, and coordinating with local, state, and federal agencies. Ms. Zeoli was task leader, managing teams in New York and California and was the primary author of numerous technical reports in support of the EIR/EIS including Historic Properties Survey Report (HPSR), Historic Architectural Survey Report (HASR), Finding of Effects Report (FOE), and Built Environment Treatment Plan (BETP).

Chicago Transit Authority (CTA), North Red Line Station Improvements, City of Chicago, Illinois: Architectural Historian. Project involved a Section 106 assessment for the rehabilitation of 8 stations along the North Red Line elevated railroad in the City of Chicago. The work included background research, field survey, National Register of Historic Places eligibility evaluations, effects assessments, and submission of Historic Architectural Screening reports for submission to the Illinois Historic Preservation Agency (IHPA) for review and concurrence.

New Jersey Turnpike Interchange, 6-9 Widening, New Jersey Turnpike Authority (NJTA), Cranbury Township, New Jersey: Architectural Historian. Project involved producing historic signage marking the spot where the newly widened turnpike crosses the National Register-eligible Camden & Amboy Railroad Historic District. The work was completed in compliance with a NJDEP Freshwater Wetlands permit. Work included background research, drafting text for the sign and coordination with the NJSHPO and sign fabricator.

St. Joseph North Pier Inner Light (St. Joseph, MI), Green Bay Harbor Entrance Light (Green Bay, WI), and Grand Marais Light (Grand Marais, MN): Architectural Historian and Photographer. Project was undertaken as mitigation for the replacement of three historic Fresnel lenses with LED lights. Effort consisted of photographic documentation of the lighthouses and lanterns and archival preparation of prints in accordance with each State Historic Preservation Office requirements.

Columbia Pike Transit Initiative, Washington Metropolitan Transit Authority (WMATA), Fairfax County, Virginia: Architectural Historian. Project involved the completion of Section 106 studies to evaluated alternatives that included enhanced bus or streetcar service along a heavily developed commercial and residential corridor, with numerous historic resources. The work included background research, historic architectural survey, and the preparation of approximately 60 reconnaissance-level survey forms for the Virginia Department of Historic Resources.

Cultural Resources Survey: Proposed Shot Tower Metro Station Hardening, City of Baltimore, Maryland: Architectural Historian and Principal Investigator. Project consisted of a Cultural Resources Survey in accordance with Section 106 for the Maryland Transit Authority. Conducted background research, field survey, and prepared a report to documenting and evaluating historic architectural resources in the project area including the Jones Falls Conduit and a portion of the Union Railroad Historic District.

Millhurst Mill HABS Level III Recordation, Manalapan Township, Monmouth County, New Jersey: Senior Architectural Historian. Project involved HABS Level III Recordation of the National Register-eligible, late-nineteenth century flour and feed mill. The project was undertaken to mitigate the adverse effect of the proposed reconstruction of Bridge MN-10 and the rehabilitation of the Millhurst dam. Ms. Zeoli conducted primary and secondary historical research to prepare a detailed history of the site and photographic documentation designed to capture character-defining features of the mill, dam, millpond, and raceway.

St. Peter the Apostle Church Convent, City of New Brunswick, Middlesex County, New Jersey: Historic Preservation consultant for the adaptive reuse of the church convent as a student ministry center. The church and convent were listed on the National Register of Historic Places in 2005 and the subject of an historic preservation easement held by the New Jersey Historic Preservation Trust. Ms. Zeoli coordinated with the Trust and the project team (church, architects, construction manager, and contractors) to ensure compliance with the Secretary of the Interior's Standards for Rehabilitation.

Ralston Cider Mill, Mendham, Morris County, New Jersey: Architectural Historian and Principal Investigator. Project consisted of the preparation of an addendum to the Historic Preservation Plan conducted in anticipation of the reconstruction of the mill's early twentieth century cider distillery. The project also included an investigation of remnant mill equipment (pulley system) and comparative research to determine its previous function. Work consisted of primary and secondary research, comparative analysis, and documentation. The work was funded by the Trustees of the Ralston Cider Mill.

Springfield Avenue Bridge Replacement, Cranford Township, Union County, New Jersey: Architectural Historian. The work consisted of an Intensive-Level Architectural Survey and evaluation of historic architectural resources within the Area of Potential Effects for the proposed replacement of a historic bridge that was a contributor to three National Register-eligible historic districts. The work was completed in compliance with a NJDEP Freshwater Wetlands permit.

Woodford-Fishback-Venable Farm, Winchester, Clark County, Kentucky: Architectural Historian. Prepared the nomination of the early-nineteenth century Woodford-Fishback-Venable Farm to the National Register of Historic Places. Cultural resources on the property boundaries reflect how patterns of traditional diversified agriculture were adapted to natural features in the Inner Bluegrass region. Ms. Zeoli conducted primary and secondary research and prepared the nomination according to the National Register of Historic Places guidelines. The farm was listed on the National Register in July 2008.

Upper Reaches of Boone Creak Rural Historic District, National Register of Historic Places Nomination, Fayette and Clark Counties, KY: Architectural Historian. Project consisted of the preparation of a nomination of the Upper Reaches of Boone Creek Rural Historic District. The district is a 10,742 acre rural historic landscape in Central Kentucky that has been engaged in agricultural pursuits since the settlement period. Ms. Zeoli conducted primary and secondary research, surveyed and photographed the district, and published the nomination according to National Register of Historic Places guidelines. The district was listed in the National Register of Historic Places in July 2009.

Philadelphia Civic Center, HABS Level II Documentation, City of Philadelphia, Pennsylvania: Cultural Resource Specialist and Project Manager. Project consisted of a Level II HABS Documentation of the Philadelphia Civic Center before its demolition in 2005 and its replacement with the Perelman Center for

Advanced Medicine in 2008. Documentation included primary and secondary research, digital photography, recordation of historic features, and narrative description. Ms. Zeoli also assisted a professional photographer with large-format, HABS-quality photography of the building.

Adaptive Reuse of Memorial Hall, City of Philadelphia, Pennsylvania: Draftsman and Conservation Intern. Project consisted of the adaptive reuse of Memorial Hall for the Please Touch Museum. The museum was built in 1875 to serve as the art gallery for the Centennial International Exhibition in Fairmount Park in 1876. It is one of only two remaining buildings out of the over 200 buildings constructed for the Exposition fairgrounds. Ms. Zeoli worked with the preservation architect and architectural conservator to complete a detailed conditions assessment of historic features and prepare construction drawings in preparation for rehabilitation and adaptive reuse of Memorial Hall.

RE: Request for Project Review
New Hampshire Capitol Corridor Rail and Transit Study
Concord, Merrimack County; Manchester and Nashua, Hillsborough County, NH

Dear Ms. Dutton:

Enclosed, please find a Request for Project Review (RPR) and supplemental documentation for the proposed New Hampshire Capitol Corridor Rail and Transit Study. The New Hampshire Department of Transportation (NHDOT) is working to evaluate a diverse set of rail and bus options for improving connectivity and passenger service between the major population centers of New Hampshire and metropolitan Boston. The Project will evaluate approximately 60-miles of existing railroad in New Hampshire that passes through Concord in Merrimack County and Manchester and Nashua in Hillsborough County, paralleling the Merrimack River the majority of the route.

It is anticipated that the Project will receive funds from the Federal Transportation Administration (FTA) and the Federal Railroad Administration (FRA). Federal licenses, permits, or approvals may also be required as part of this project. As a federally funded/licensed project, the Project is subject to review under Section 106 of the National Historic Preservation Act of 1966, as amended (36 CFR Part 800). To satisfy requirements under Section 106, URS has prepared and attached a Phase IA Archaeological Survey and a Reconnaissance-Level Historic Architectural Survey for your review.

If you have questions, please do not hesitate to contact me at 609-386-5444 or via e-mail at joel.dworsky@urs.com .

Yours truly,

Joel G. Dworsky, RPA
Senior Archaeologist / Geospatial Analyst

This form is updated periodically. Please download the current form at http://www.nh.gov/nhdhr/review. *Please refer to the Request for Project Review for Transportation Projects Instructions for direction on completing this form.* Submit 2 copies of this project review form for each project for which review is requested. Include 1 self-addressed stamped envelope to expedite review response. Project submissions will not be accepted via facsimile or e-mail. This form is required. Review request form must be complete for review to begin. Incomplete forms will be sent back to the applicant without comment. Please be aware that

this form may only initiate consultation. For some projects, additional information will be needed to complete the Section 106 review. All items and supporting documentation submitted with a review request, including photographs and publications, will be retained by the DOT and the DHR as part of its review records. Items to be kept confidential should be clearly identified. For questions regarding the DHR review process and the DHR's role in it, please visit our website at: http://www.nh.gov/nhdhr/review or contact the R&C Specialist at christina.st.louis@dcr.nh.gov or 603.271.3558.

PROJECTS CANNOT BE PROCESSED WITHOUT THIS INFORMATION

Project Boundaries and Description

☒ Attach the relevant portion of a 7.5' USGS Map (photocopied or computer-generated) ***indicating the proposed area of potential effect (APE).*** *(See RPR for Transportation Projects Instructions and R&C FAQs for guidance. Note that the APE is subject to approval by lead federal agency and SHPO.)*

☒ Attach a detailed narrative description of the proposed project. *(see attached reports)*

☒ Attach current engineering plans with tax parcel, landscape, and building references, and areas of proposed excavation, if available.

☒ Attach photos of the project area/APE with photo key (overview of project location and area adjacent to project location, and specific areas of proposed impacts and disturbances.) *(Blank photo logs are available on the DHR website. Informative photo captions can be used in place of a photo log.)*

☒ A DHR file review must be conducted to identify properties within or adjacent to the APE. Provide file review results in **Table 1**. *(Blank table forms are available on the DHR website.)*
File review conducted on 03/06/2014.*

**The DHR recommends that all survey/National Register nomination forms and their Determination of Eligibility (green) sheets are copied for your use in project development.*

Architecture

Are there any buildings, structures (bridges, walls, culverts, etc.) objects, districts or landscapes within the APE? ☒ Yes ☐ No
If no, skip to Archaeology section. If yes, submit all of the following information:

☒ Attach completed **Table 2**. See Table 4-4, page 27

☒ Photographs of ***each*** resource or streetscape located within the APE. Add to the photo key and photo log noted above. (Digital photographs are accepted. All photographs must be clear, crisp and focused.)

☒ Copies of National Register boundary (listed *or* eligible) mapping, and add National Register boundaries for listed and eligible properties to the 7.5' USGS project map *(if applicable).*

Archaeology

Does the proposed undertaking involve ground-disturbing activity? ☐ Yes ☐ No
If yes, submit all of the following information:

☐ Description of current and previous land use and disturbances.

☐ Available information concerning known or suspected archaeological resources within the project area (such as cellar holes, wells, foundations, dams, etc.)

Please note that for many projects an architectural and/or archaeological survey or other additional information may be needed to complete the Section 106 process.

AGENCY COMMENT *This Space for DOT and Division of Historical Resources Use Only*

Sent to DHR; Authorized DOT Signature:_____ Date: _____

☐ Insufficient information to initiate review.

☐ Additional information is needed in order to complete review.

Comments:

If plans change or resources are discovered in the course of this project, you must contact the Division of Historical Resources as required by federal law and regulation.

Abstract

URS Corporation (URS) conducted a Phase IA background data collection and archaeological sensitivity assessment of the proposed construction APEs for the New Hampshire Department of Transportation's Capitol Corridor Rail Transit Study. This report presents the results of a Phase IA sensitivity assessment and field reconnaissance of a project area, spanning the existing rail corridor from Lowell, Massachusetts, to Concord, New Hampshire. This report focuses on the section of the project area located in New Hampshire, contained within Hillsborough and Merrimack Counties, with specific attention paid to the APEs of proposed station and layover locations. All of these proposed APEs were assessed to determine their archaeological sensitivity, accomplished by reviewing the known archaeological resources that occur within six separate study areas in a 1-x-5-kilometer radius surrounding the proposed construction APEs. This effort was combined with a review of the pre-contact and historic contexts of the region and synthesized into determinations of archaeological potential for each study area.

URS assessed the archaeological sensitivity for the six major study areas encompassing the entirety of the proposed project APEs within New Hampshire. Overall, the pre-contact archaeological potential for the study areas remained consistently high, owing in large part to the proximity of the construction APEs to the Merrimack River. Determination of historical archaeological sensitivity varied from low to high potential. Proximity to areas of intensive settlement tended to increase the potential of encountering historic archaeological resources. Historical archaeological sensitivity is subdivided into groups by site function. Of the site types surveyed, the most likely resources to be encountered are related to industry, specifically mills. These resources were frequently situated along the river and its tributaries, from which they derived operational power and transportation. As the extant rail bed follows the course of the Merrimack River, the likelihood of encountering industry-related resources is high. Residential and transportation-related resources have the next highest potential, but such resources were largely confined to study areas near city centers. Farmsteads, while frequently present, were spatially more diffuse and located farther from the river, reducing the likelihood of encountering resources of this type.

URS performed a Phase IA field reconnaissance of the proposed construction APEs in March 2014. This reconnaissance concentrated on documenting the current state of the APEs and identifying any cultural resources that might have been present. The only cultural resource encountered during this reconnaissance was a complex of foundations within the Crown Street APE, in the area slated to become a parking facility. Overall, the APEs were largely contained within the boundaries of the existing rail bed. During the field reconnaissance, the subsurface archaeological potential of the soils within each APE was not investigated. Therefore, Phase IB archaeological survey should be conducted in areas of high or moderate historical and pre-contact archaeological sensitivity where ground-disturbing construction activities are planned. Should the proposed project move forward, URS recommends the following actions:

Concord: Stickney Avenue	High pre-contact and post-contact archaeological potential. URS recommends Phase IB archaeological survey. No further survey recommended in areas currently covered by pavement.

	However, if pavement is removed, a Phase IB survey is recommended in these areas, as well.
Manchester: Spring Street	High pre-contact and post-contact archaeological potential. No further survey is recommended, as no ground-disturbing activities are planned. URS recommends a Phase IB survey for any areas where extant soil caps are removed in order to dig footings for the proposed rail platform.
Manchester: Granite Street	High pre-contact and post-contact archaeological potential. URS recommends a Phase IB survey for any areas where extant soil caps are removed in order to dig footings for the proposed rail platform.
Manchester: Granite Street South	High pre-contact and post-contact archaeological potential. No further survey is recommended, as no ground-disturbing activities are planned. If plans are altered to include ground disturbance, then a Phase IB survey is recommended.
Queen City Bridge Layover	High pre-contact and post-contact archaeological potential. No further survey is recommended, as no ground-disturbing activities are planned. If plans are altered to include ground disturbance, then a Phase IB survey is recommended.
Manchester: Cemetery	High pre-contact archaeological potential. Moderate to low post-contact archaeological potential. URS recommends Phase IB archaeological survey.
Manchester: Wastewater Treatment Facility	High pre-contact archaeological potential. Moderate to low post-contact archaeological potential. No further survey is recommended, as no ground-disturbing activities are planned. If plans are altered to include ground disturbance, then a Phase IB survey is necessary.
Manchester: MHT Airport-Ray Wieczorek Drive	High pre-contact archaeological potential. Low post-contact potential except for the high potential of encountering industrial historic resources. No further survey is recommended, as no ground-disturbing activities are planned and the construction APE has been previously surveyed during the construction of the Ray Wieczorek Bridge. If the APE is amended and the new plan calls for ground disturbance in areas not currently contained within the APE or the removal of existing soil caps within the APE, then URS recommends a Phase IB survey as the surrounding area has demonstrated pre-contact potential.

Nashua: Crown Street	High pre-contact and post-contact archaeological potential. URS recommends Phase IB archaeological survey in the area of the proposed parking facility. No further survey recommended in the area of the proposed station location, as it is currently covered by pavement or part of the extant rail bed.
Nashua: Spit Brook	High pre-contact and post-contact archaeological potential. The post-contact archaeological potential while generally low throughout the Nashua South Study Area is high at this location due to the documented presence of a former industrial facility in the proposed project area. 1. Station APE: No further survey recommended. 2. Layover APE: URS recommends Phase IB survey to assess the boundaries and significance of the identified Spit Brook Prehistoric Site. 3. Parking Area APE: Contingent on construction methodology and possibility of grading. If no ground-disturbing activities are planned, than no further survey is recommended. If ground disturbance is possible, than a Phase IB survey is recommended.
Nashua: Pheasant Lane Mall	High pre-contact archaeological potential and low post-contact archaeological potential. URS recommends Phase IB survey. Should construction call for the importation of fill instead of ground disturbance to construct the rail platform, survey will not be necessary. Phase IB is recommended prior to the construction of the proposed parking structure.

1.0 Introduction

The Federal Railroad Administration (FRA), as the lead federal agency, the Federal Transit Administration, as a cooperating agency, and the New Hampshire Department of Transportation (NHDOT), as project sponsor, are proposing to evaluate the feasibility of developing new rail and transit services in the 73-mile corridor between Boston, Massachusetts, and Concord, New Hampshire (Figure 1). To satisfy requirements under the National Environmental Policy Act (NEPA) of 1969, as amended, NHDOT is preparing an environmental assessment (EA). The New Hampshire Capitol Corridor Rail and Transit Study is a federal undertaking and, as such, is also subject to review under Section 106 of the National Historic Preservation Act of 1966 (NHPA), as amended, and the implementing regulations in 36 CFR Part 800. To initiate consultation under Section 106 among the FRA, FTA, NHDOT, and the New Hampshire Division of Historic Resources (NHDHR), URS has prepared this Phase IA archaeological assessment. The architectural and archaeological studies will also serve to supplement and inform the EA being completed as part of the NEPA process. The purpose of this reconnaissance-level archaeological survey is to record the presence or absence of previously identified and unidentified cultural resources within the area of potential effects (APE). The Phase IA archaeological assessment has been prepared in accordance with the guidelines set forth by the NHPA and the NHDHR.

1.1 Project Description

As noted above, New Hampshire Capitol Corridor Rail and Transit Study is defining and evaluating opportunities to address transportation needs and preferences that involve transit and rail options in the 73-mile corridor between Boston, Massachusetts, and Concord, New Hampshire. While Massachusetts Bay Transportation Authority (MBTA) commuter rail service currently operates between Boston and Lowell, there has not been passenger service north of Lowell since it was discontinued in 1967. A public-private partnership, supported by the state of New Hampshire, operates roughly 50 daily bus roundtrips within the corridor between New Hampshire and Boston; this service typically carries 1,800 passengers per day.

Increasing transportation demand and growing concerns about mobility, economic development, and quality of life have led the citizens and officials in New Hampshire and Massachusetts to explore options to improve transit service along the northern end of the Capitol Corridor. The NH Capitol Corridor Study is evaluating a diverse set of rail and bus options for improving connectivity in the Capitol Corridor by leveraging existing transportation infrastructure, including Pan Am Railway, Route 3, and I-93. The study, which will be completed in late 2014, will result in the recommendation of a preferred investment strategy that is responsive to local transportation need and the region's economic, social, financial, and environmental context, and that will be competitive for federal construction funding.

This report presents the results of a Phase IA reconnaissance of a project area spanning the existing rail corridor from Lowell, Massachusetts, to Concord, New Hampshire. This report focuses on the section of the project area located within New Hampshire contained within Hillsborough and Merrimack Counties. The project corridor is situated in the Merrimack River Valley and runs parallel to the aforesaid river for its entire course (see Figure 1). URS

Corporation (URS) conducted this Phase IA archaeological assessment under contract with NHDOT. Background research and field reconnaissance for the project was conducted throughout March and April 2014 by Joel Dworsky, Daniel Cassedy, and Andrew Wyatt, under the direction of Matthew Harris, Principal Investigator.

The Capitol Corridor project will ultimately involve the construction of 5 commuter rail stations and one layover location. Additionally, a total of total of 19.4 miles of railroad track modification (Table 1). Though only six sites will ultimately be selected for construction, this report considers 11 potential construction locations from which the final locations will be selected. While new track will be constructed during this project, all work will be limited to the confines of the existing railroad bed. This railroad bed originally was designed to accommodate a set of two parallel tracks, but in 1960, the secondary track was removed and the current rail line contains only one set of track. Given the ability of the existing rail bed to accommodate the additional rail, the bulk of the necessary rail modifications can be completed within the confines of the extant rail bed, so adjacent areas will not be impacted and need not be considered during this study. The proposed station/layover locations, on the other hand, will be new construction and, as such, are the principal focus for the Phase IA reconnaissance. These potential station/layover locations are situated in the towns of Concord, Manchester, and Nashua along the existing rail bed, which runs along the Merrimack River.

Table 1-1 Survey Locations: Potential Stations and Layovers

Site	Stations	Layovers
Concord: Stickney Avenue	X	X
Manchester: Spring Street	X	
Manchester: Granite Street	X	
Manchester: Granite Street South		X
Manchester: Queen City Bridge Layover		X
Manchester: Cemetery		X
Manchester: Wastewater Treatment Facility		X
Manchester: MHT Airport-Ray Wieczorek Drive	X	
Nashua: Crown Street	X	
Nashua: Spit Brook	X	X
Nashua: Pheasant Lane Mall	X	

The primary focus of this report is to present a synthesis of the prior research conducted near, along, and within the study corridor and from that analysis make recommendations on the necessity of further archaeological work. While the project corridor is linear and contained within the Merrimack Valley, it is not continuous. Track modifications and new station/layover locations are clustered near major town/cities and are separated by long expanses of unmodified track. In the areas between these proposed station and layover locations, the existing track will be replaced with modern rails to ensure the structural integrity and therefore safety of the rail line. The route of the track in these areas will not be altered, so there is no potential for adverse effect. For ease of discussion, the project corridor in New Hampshire has been divided into three principal study areas, each named for the largest town in proximity. The northernmost section, Concord, is located within the town of Concord in Merrimack County and centers on a single station location in the center of the city. The middle study area is the largest and falls within Hillsborough County. This study area bears the name of Manchester, which is the principal city

in the area. This area contains six of the new station/layover locations, although many of the aforesaid locations occur outside the city center. The southernmost study area, Nashua, is located near the town of Nashua in Hillsborough County and contains three new station locations. Where it is necessary for mapping clarity, these three sections are divided into subsections. While these subsection divisions are used for mapping, they are not used for written descriptions of study areas unless otherwise specified (for section locations see Figure 1).

2.0 Environmental Background

2.1 Physiography, Drainage, Bedrock Geology, and Soils

The study areas are located in the New England Upland Section of the New England physiographic province (Fenneman 1938) and are drained by the Merrimack River. Major tributaries of the Merrimack River within or near the study areas include the Turkey, Soucook, Piscataquog, and Nashua Rivers. All project components are located within the Merrimack River Valley. Glacial outwash terraces and plains, stream terraces, and floodplains of the Merrimack River are the principal landforms.

Late to Early Devonian Concord Granite, composed primarily of gray two-mica granite, underlies Concord and the surrounding area. The primary bedrock mapping unit for Manchester is the Late Proterozoic Massabesic Gneiss Complex. This unit consists of pink biotite grantite intruded into gneissic and granulose metasedimentary and metavolcanic rocks. The area surrounding Nashua is underlain by the two-mica granite of northern and southeastern New Hampshire, which is of a similar age and composition as the Concord Granite. Both the Concord and two-mica granites were formed during the Acadian Orogeny, between circa 465 to 400 million years before present (B.P.) (Bennett et al. 2006). These bedrock units were scoured by the advance of the Laurentide ice sheet during the Wisconsinan glacial cycle and are variably exposed on the surface in uplands (Goldthwait et al. 1951:21–22).

Soil data for the project area was derived from the online Web Soil Survey (2014) and is summarized in Table 2-1. Urban land is mapped at the Stickney Avenue Station (Concord), and at Spring Street Station, Granite Street Station, and the Wastewater Treatment Facility Layover (Manchester). The urban land mapping unit designates areas in which fill and/or impervious cover comprise more than 85% of the ground surface. In Nashua, Windsor-urban land complex soils are mapped at the Crown Street Station and in a portion of the Split Brook Station and Layover. This mapping unit includes both urban land and the potential for Windsor series soils, the latter of which formed in outwash deposits on glaciofluvial landforms or in aeolian deposits on dunes.

Soil mapping indicative of potentially less-disturbed conditions is present at the following facilities: Cemetery Layover (Manchester), Ray Wieczorek Drive Station (Manchester), Spit Brook Station and Layover (Nashua), and Pheasant Lane Mall Station (Nashua). The Cemetery Layover (Manchester) is predominantly mapped as Windsor loamy sands. This mapping unit is characterized as very deep and excessively well-drained soil formed in outwash deposits on glaciofluvial landforms or in aeolian deposits on dunes. A typical profile exhibits a loamy sand A or Ap horizon overlying a sequence of loamy sand to sand Bw horizons to a depth of approximately 0.64 meters. The lowermost Bw horizon overlies sand C horizon that can extend to 1.65 meters or more. The Cemetery Layover also contains a smaller area mapped as Rippowam fine sandy loam, a very deep, poorly drained soil developed in alluvium on floodplains. A typical profile includes a fine sandy loam Ap horizon overlying gleyed fine sandy loam to loamy sand B and C horizons. Depth to lateral accretion deposits is approximately 0.69 meters.

Table 2-1 - Principal Soil Types within the Proposed APEs

Project Facility	Mapping Unit Name	Depth and Drainage	Genesis and Location

Project Facility	Mapping Unit Name	Depth and Drainage	Genesis and Location
Stickney Avenue Station and Layover	Urban land (85% covered)	No data	No data
Spring Street Station and Platform (Disturbed by RR and other)	Urban land (85% covered)	No data	No data
Granite Street Station (Disturbed by RR and other)	Urban land (85% covered)	No data	No data
Cemetery Layover (Appears intact)	Windsor loamy sand	Very deep, excessively drained	Formed in outwash or aeolian deposits on Late Wisconsinan glaciofluvial landforms or dunes
	Rippowam fine sandy loam	Very deep, poorly drained	Formed in alluvium on floodplains (suggests that Windsor may be mis-mapped)
Wastewater Treatment Facility Layover (Strong potential for RR disturbance)	Urban land (85% covered)	No data	No data
MHT/Ray Wieczorek Drive Station (N. of bridge somewhat disturbed, S. of bridge looks intact w/ Pointer Club Brook confluence, But Dworsky says lots of Phase II work here)	Agawam fine sandy loam	Very deep, well drained	Formed in "water-deposited" materials on outwash plains and high stream terraces
	Ninigret very fine sandy loam	Very deep, moderately well drained	Formed in loamy over gravelly outwash on glaciofluvial landforms
Crown Street Station (Strong potential for factory-related disturbance)	Windsor-Urban land complex	Very deep, excessively drained	Formed in outwash or aeolian deposits on Late Wisconsinan glaciofluvial landforms or dunes
Spit Brook Station and Layover (poss. former Dow Chemical Site Site looks recently landscaped)	Windsor-Urban land complex	Very deep, excessively drained	Formed in outwash or aeolian deposits on Late Wisconsinan glaciofluvial landforms or dunes
	Occum fine sandy loam, high bottom	Very deep, well drained	Formed in recent alluvium on floodplains
	Pootatuck fine sandy loam	Very deep, moderately well drained	Formed in recent alluvium on floodplains
Pheasant Lane Mall Station (Strong potential for RR disturbance)	Suncook loamy fine sand	Very deep, excessively drained	Formed in recent alluvium on floodplains, subsoil consists of C horizons, may contain thin Ab horizons

The dominant soil mapping unit at the Ray Wieczorek Drive Station is Agawam fine sandy loam. This very deep, well-drained soil formed in water-deposited materials on outwash plains and high stream terraces. A typical profile displays a fine sandy loam Ap horizon overlying sandy loam Bw horizons to a depth of approximately 0.66 meters. The Bw horizons are underlain by structureless loamy fine sands to loamy sand C horizons that may include varying amounts of gravel. A smaller area of Ninigret very fine sandy loam is mapped in the southwestern corner of Ray Wieczorek Drive Station. This mapping unit is characterized as very deep, moderately well-drained, and formed in loamy deposits over gravelly outwash on glaciofluvial landforms. A

typical profile is similar in most respects to Agawam; however, the depth to the C horizon is shallower in Ningret soils.

The majority of the Spit Brook Station and Layover (Nashua) is mapped as Windsor-urban land complex, discussed above. Smaller areas of Occum fine sandy loam, high bottom, and Pootatuck fine sandy loam are mapped in the southern portion of the proposed facility. Both mapping units are classified as very deep and well drained to moderately well drained, and formed in recent alluvium on floodplains. Profiles for the two mapping units are similar; however, Pootatuck soils tend to displayed features indicative of impeded drainage (e.g., iron masses) and can contain thin Ab horizons.

Soils at Pheasant Lane Mall Station are mapped as Suncook loamy fine sand. This mapping unit is characterized as a very deep and excessively drained soil formed in recent soils on floodplains. A typical profile consists of a loamy fine sand Ap overlying stacked fine to coarse sand C horizons to depths exceeding 1.65 meters. The mapping unit can sometimes contain thin buried A horizons.

2.2 Paleoenvironment

As glacial ice ablated in New Hampshire between circa 14,600 and 12,600 B.P. (Ridge 2003), thick till was emplaced on uplands, and three successively higher proglacial lakes occupied what would become the Merrimack River Valley (Lakes Tyngsboro, Merrimack, and Hooksett from south to north). Koteff et al. (1984) suggests that these lakes drained sometime after 13,000 B.P., and the southern margin of the Laurentide ice sheet retreated from the upper Merrimack drainage by circa 12,000 B.P. (Ridge 2003: Figure 3.7). During this interval, the ancestral Merrimack River began eroding and reworking the glaciolacustrine sediments and constructing a series of lower stream terraces. Aeolian deposition capped stream terrace and proglacial lake deposits in places (Koteff et al. 1984:391–392), a process that continued into the late Holocene based on Dincauze's (1976:10–11) interpretation of soil parent material at the Neville Site.

Low-growing tundra vegetation consisting of mosses, ferns, sedges, and grasses—along with dwarf birch and alder—colonized newly deglaciated landscapes. Pollen-based vegetation reconstructions for northern New England vary regarding the earliest trees to colonize tundra. Davis and Jacobson (1985) indicate open poplar woodland was present near Concord by 13,000 B.P. Davis (1981), however, suggests that spruce dominated the first patchy, open woodlands in southeastern and central New Hampshire between circa 12,700 and 11,800 B.P. In both reconstructions, open woodlands bordered tundra to the west and north. At the same time, a mixed woodland composed of poplar, spruce, and jack pine/red pine existed in the vicinity of Nashua. After 12,000 B.P., the mixed woodland had moved north and west, replacing open woodland in the vicinity of Concord, while more closed forests dominated by spruce (together with fir, birches, and poplar) had developed in southeastern New Hampshire (Davis and Jacobson 1985). Newby et al. (2005) have linked a retraction of spruce/fir forests to southern Maine and southeastern New Hampshire and expansion of tundra between circa 11,000 and 10,000 B.P. to the Younger Dryas climate episode, coinciding with the arrival of Paleoindians in northern New England.

As in the case of flora, faunal communities of the Late Glacial had no modern analogs. These communities were characterized by the association of a number of Late Pleistocene species that are either extinct (e.g., mammoth, mastodon) or regionally extirpated (e.g., caribou) with other species (e.g., deer, moose, black bear) that have persisted in the area into the modern period (Lundelius et al. 1983). Although there is no archaeological evidence in New England for Paleoindian exploitation of mammoth or mastodon, radiocarbon dates for these and other extinct species indicate that they were available to at least the earliest Paleoindian groups. Small fragments of calcined caribou bone have been recovered from the Whipple and Bull Brook Paleoindian sites (Spiess et al. 1998:226).

Rapid warming after the Younger Dryas fostered the arrival of oak, white pine, and maple into northern New England between 10,000 and 9,000 B.P. These species quickly replaced spruce and fir, resulting in a new composition of the closed forests of southeastern New Hampshire and southern Maine that came to be dominated by pine. Hemlock, beech, and birch followed between 9,000 and 8,000 B.P. The growing numbers and density of mast-producing species in early Holocene forests would have increased the carrying capacity of the environment, resulting in higher terrestrial game populations and diversified subsistence opportunities for Native American groups. Between 9,000 and 6,000 B.P., the center of pine abundance moved northwest, and forests composed of pine, birch, maple, beech, and hemlock became dominant. Other mast-bearing trees, hickory and chestnut, arrived in northern New England at 5,000 and 2,000 B.P., respectively (Davis 1981; Gaudreau 1988).

Early historic period vegetation patterns in the Northeast include a conifer-hardwood forest region in the northern sections, and deciduous forests in the southern portions. This modern ecotone extended from southern Maine west along the Massachusetts-New Hampshire border. Pollen records indicate that the ecotone between the two major zones was established in the early Holocene and became more pronounced between 8,000 and 6,000 B.P. While the ecotone was stable from the early Holocene, the species composition of the two forest zones continued to change throughout the late Holocene (Gaudreau 1988).

3.0 General Cultural and Historical Background

3.1 Pre-Contact Background

3.1.1 Paleoindian Period (Circa 11,500–9400 B.P.)

Although several sites south of New England (i.e., Meadowcroft, Cactus Hill, Miles Point) may represent pre-Paleoindian habitation sites, the earliest documented occupation of New England and the Maritimes dates to the Paleoindian period, from approximately 11,500 to 9600 B.P. Paleoindian sites are most commonly identified by the presence of distinctive fluted and unfluted laceolate projectile points. Other parts of the toolkit included formal flake tool types and large, bifacial cores. In the greater Northeast, Paleoindian toolkits are marked by a conspicuous use of high-quality cryptocrystalline lithic materials that often originate at considerable distances from their point of discard. The former characteristic is inferred to result from a need for durability over numerous episodes of intensive use at locations distant from sources (Goodyear 1989; Spiess et al. 1998:239–242), while the distances from sites to sources have been used to estimate maximum travel distances.

In a recent synthesis of Paleoindian data for New England and the Maritimes, Spiess et al. (1998: 235–239) proposed a series of five chronological phases for the period based on stylistic changes in projectile forms. The earliest two phases, Bull Brook and Vail-Debert, are roughly coeval. Bull Brook phase fluted points are relatively straight-sided with moderately deep basal concavities and flutes that exceed half the length of the point. Vail-Debert fluted points are generally larger and exhibit the same outline as Bull Brook points, but have deep basal concavities and shorter flutes. Dates for these phases range from circa 11,500 to 10,500 B.P. Fluted points of the following Michaud-Neponset phase are generally narrower and thinner than earlier fluted point styles, display flaring basal ears, and are often fluted to within 10 millimeters of the tip. Crowfield phase fluted points expand markedly from the base, reach maximum width near midpoint, and display long, often multiple flutes. Michaud-Neponset and Crowfield points both display shallow basal concavities compared to Bull Brook and Vail Debert points. Spiess et al. suggested that the Michaud-Neponset phase ranged from 10,310 to 10,070 B.P. The Nicholas phase is the final proposed Paleoindian phase. The Nicholas point is unfluted, small, thin, and expands at the base, similar to Crowfield points. Dates for this phase are few and range from circa 10,120 to 9400 B.P.

In terms of general settlement patterns for the region, Spiess et al. (1998:229–230) have noted that the majority of larger Paleoindian sites contain at least one discrete locus of stone tools and debitage measuring 4 to 8 meters in diameter that are separated by sterile space. The Bull Brook site exhibited 42 such loci, followed by Debert (11 loci), Vail and Michaud (eight loci each), Bull Brook II (six loci). The non-overlapping character of loci suggests that each represent short-term single occupations at each site. Subsistence data is sparse; however, faunal remains from several sites are limited to calcined medium to large mammal bone. Calcined caribou bone has been identified at the Whipple Site, calcined caribou and beaver bone are present at Bull Brook, and calcined caribou, Arctic fox and hare have been identified at the Udora Site in Ontario. Extremely small numbers of carbonized fruit and berry seeds have been recovered from the Michaud and Hedden Sites in Maine. Spiess et al. (1998:223–227) suggested that these data

support a model of Paleoindian subsistence that is similar in its broad outlines to ethnographic examples from the subarctic region, featuring specialized caribou hunting in some seasons combined with general foraging at other times.

The Whipple Site, located on an outwash terrace above the Ashuelot River in the southwestern corner of the state, is the most extensively excavated Paleoindian site in New Hampshire (Curran 1984, 1994). The site was comprised of three small, spatially separated loci, all of which produced a wide variety of stone tools types, and two of which contained datable features. Curran assigned the site to the Bull Brook phase of Grimes et al. (1984) based on formal similarities between the Whipple fluted points and those from the Bull Brook Site. Conventional radiocarbon dates from Locus C ranged from 9820 ± 420 B.P. to 11, 430 ± 395 B.P. (Curran 1984:13); however, a weighted mean of three assays yields a date of 10,680±400 B.P. The site contained a large number of calcined cervid bones, three of which were identified as caribou. Speiss et al. (1998:241–242) suggested that the Whipple assemblage is dominated by Champlain Valley chert and appreciable amounts of Munsungun chert from northern Maine, with much lower utilization of more locally available Cheshire quartzite. Curran interpreted the loci as short-term occupations by small family or task groups, and suggests that the loci may not have been coeval based on differing patterns of raw material discard (1984:14–15).

Isolated fluted points and small Paleoindian components have been identified in the Merrimack River Valley. Dincauze (1976:118) reported a fluted point tip from a later context at the Neville Site, and Curran (1994:41–45) described a complete fluted point from potentially intact subsurface contexts at the nearby Smyth Site. Curran (1994:41–43) also discussed the Thornton's Ferry Sites (27-HB-1, 27-HB-2), both of which are located on sandy glaciofulvial landforms within the former bed of glacial Lake Merrimack. Site 27-HB-2 yielded a single felsite fluted point base, jasper flake tools, and rhyolite debitage in subsoil deposits. At the time of Curran's reporting, no clearly diagnostic Paleoindian artifacts had been recovered from 27-HB-1; however, chert flake tools and debitage on non-local material were recovered at depth in the subsoil below Middle Archaic types, which were deemed to be possibly Paleoindian. Additional excavation and analysis in 2001 allowed Boisvert and Bennett (2004) to make a convincing case based on stratigraphy, raw material types, and debitage attributes that the site's lower component is Late Paleoindian in age.

3.1.2 ARCHAIC PERIOD (CIRCA 9400–2500 B.P.)

The Archaic period exhibits an increase in the density and horizontal dispersal of archaeological remains. It is characterized by a reliance on both animals and wild plant resources, which became increasingly stabilized and broad based over time. Group organization was presumed to still be fairly mobile, making use of seasonally available resources in different areas of the Southeast. Caldwell (1958) has termed the maximizing adaptation (scheduled hunter-forager) to the environment in the Eastern woodlands during the Archaic period "primary forest efficiency." Group size gradually increased during this period, culminating in a fairly complex society in the Late Archaic.

The Early Archaic period (circa 9400–7000 B.P.) is marked by the end of the Pleistocene glacial climate and extinction of megafauna. To date, evidence of Early Archaic occupations is much

more common in southeastern North America than in the Northeast. In addition, the southeastern sequence suggests a transition from Paleoindian to Early Archaic assemblages, which has not yet been demonstrated for the Northeast. Prior to 1970, there was virtually no evidence of any northeastern sites dating to the Early or Middle Archaic periods. In the last three decades, considerable information has been obtained to fill in that gap, but the picture is still incomplete. The period is characterized by greater diversity in projectile point forms and increasing reliance on diverse species of Holocene fauna, including white-tailed deer, anadromous fish, birds, and turtle (Petersen et al. 1986:9).

George Nicholas has been a frequent and vocal proponent of the idea that early Holocene occupations in the Northeast were much more abundant than was previously thought, and that they operated within an environment that was much more productive than originally described. He has identified former glacial lake basins as locations that are likely to have been established as resource-rich mosaics within a changing and somewhat unpredictable early Holocene landscape (Nicholas 1983, 1988).

Early Archaic projectile points have been found in relatively isolated contexts from the Lakes Region of New Hampshire to the lower coastal tributaries of northeastern Massachusetts (Bunker 1988:6). At least three Early Archaic components referable to Robinson's (1992) Gulf of Maine Archaic tradition are known for the Merrimack River Valley. The first to be excavated was the Weirs Beach Site, located at the outlet of Lake Winnipesauke (Bolian 1980; Maymon and Bolian 1992). The stratified Early Archaic component featured large amounts of quartz debitage, cores, steep-bite quartz endscrapers, and groundstone rods. Radiocarbon dates of 9155 ± 395 B.P. and 8985 ± 120 B.P. on wood charcoal from features placed the site in the Early Archaic subperiod. The Eddy Site (27-HB-0078), located on a stream terrace of the Merrimack River, was subjected to test excavations in 1985 in advance of topsoil mining (Bunker 1992). The site yielded a stratified sequence of Middle Archaic through Woodland occupations in the upper meter of alluvial deposits. Between approximately 1 meter and 1.77 meters below surface, four strata were encountered, each of which produced small quartz-dominated assemblages at the upper contacts of each stratum. Tools included unifaces, other flake tools, hammerstones, and one adze fragment. Quartz was the primary lithic material for cores and debitage. Radiocarbon dates on charcoal from 1.29 to 1.62 meters below surface range from 7830 ± 100 B.P. to 7595 ± 120 B.P. In 1993, excavations in the town of Merrimack by Louis Berger & Associates recovered an Early Archaic campsite at Site 27-HB-160 radiocarbon-dated at 8690 +80 B.P. (Carini 1994:IX-1). The site produced an assemblage of early-stage quartz debitage, chert bifacial reduction debris, unifacial tools, nuts, berries, and mammal bones. Neither site yielded projectile points; a minor role for bifaces and stone projectile points appears to be characteristic of pre-Neville complex Middle and Early Archaic occupations of the Gulf of Maine Archaic tradition (Robinson 1992:69).

The Middle Archaic, circa 7000–5000 B.P., is associated with warmer and drier climatic conditions. By this period, modern floral communities were established, characterized by mast-producing hardwoods. Rivers stabilized during this time and wetland and lake areas were reduced in size. Hunting continued to be important, and fish may have become a more predictable resource. There is evidence for shellfish exploitation during this period. Excavations at the Neville Site in Manchester documented the Neville stemmed point type dating to between

7800 and 7000 B.P., and the Stark stemmed point type dating between about 7600 and 6400 B.P. (Dincauze 1976). In addition, the Merrimack point type was identified as dating to the end of the Middle Archaic period, close to 6000 B.P. The Neville and Stark point types are similar in style and age to the Stanly and Morrow Mountain types that Coe (1964) defined earlier in the Southeast, but the Merrimack type appears to be more spatially restricted.

After publication of the Neville Site research, sites and isolated finds associated with these Middle Archaic complexes were increasingly recognized and reported throughout the Northeast. The Neville and Stark types have proved to be relatively common throughout New England. In the lower Merrimack River Valley, excavations at the Eddy Site revealed another substantial Middle Archaic occupation focused on riverine exploitation, and evidence for upland mast forest exploitation is documented at the Smolt Site (Kenyon 1983, 1992). Abundant evidence for lithic reduction activities comes from assemblages recovered from several Middle Archaic sites in the Lakes Region of central New Hampshire (Cassedy 1984; Starbuck 1983).

The accumulated data for the Middle Archaic period in the Northeast suggest that, during this period, the pre-contact inhabitants were forming themselves into distinct bands and settling into defined territories. These bands were establishing base camps and occupying a greater variety of special-purpose sites in a carefully planned seasonal round (Snow 1980:183). Evidence for the first use of coastal resources, such as shellfish beds, appeared during this period. Several new tool types were developed during this period, including woodworking tools, such as gouges and axes, and large groundstone semi-lunar knives, commonly known by the Eskimo name, “ulu.”

The Late Archaic period is generally dated circa 5000–2500 B.P. Prior to the 1960s, Late Archaic sites were virtually the only Archaic period sites recognized in the Northeast. William Ritchie’s work at sites like Lamoka Lake in New York had produced his seminal definition of an “Archaic” stage of culture in North American prehistory (Ritchie 1932, 1936), but no earlier complexes were known.

Throughout the Northeast, archaeologists now recognize the Late Archaic period as one in which the numbers and types of sites increased dramatically—what Snow (1980:187) described as the Late Archaic “florescence.” Unlike earlier time periods, anyone interpreting Late Archaic assemblages must contend with a sometimes confusing and complex array of data. Based on his work in New York, Ritchie (1994) recognized two major Late Archaic trajectories, the Lamoka and the Laurentian, which overlap in both time and space. Both trajectories are also represented in New England.

Although Ritchie believed Lamoka to be the oldest Late Archaic tradition, more recent research has documented that Laurentian manifestations appeared as early as the last centuries of the sixth millennium B.P. Initially, the Laurentian was subdivided into three phases—Vergennes, Brewerton, and Vosburg—based on projectile point morphology and, to some degree, chronology. These phases extend from about 5500 to 4300 B.P. (Funk 1988:36). Subsequently, the discovery of Otter Creek and Brewerton Side Notched projectile points dating to the fifth and early sixth millennia B.P. led Funk to posit a “Proto-Laurentian” assemblage composed of “broad side notched points with ground bases and notches generally resembling Otter Creek and Brewerton side notched points” (Funk 1988:29), along with “biface knives, a variety of unifacial

end and side scrapers, and common forms of 'rough stone' tools such as hammerstones and pitted stones"(Funk 1991:9). Funk and others (Tuck 1977:37) suggested that the Proto-Laurentian assemblages are "closely allied with Middle Archaic complexes of the Southeast and Midwest, chiefly identified by Raddatz, Modoc Side Notched, Big Sandy, and other large, notched points similar to the Otter Creek type" (Funk 1991:9).

What Ritchie first defined as the Lamoka culture in the Finger Lakes region has been shown to be associated with a horizon of small, narrow-stemmed projectile points that extends across southern New England, and includes such types as the Sylvan and Wading River forms from the Hudson Valley and southeastern New York, as well as the Squibnocket complex from southern New England.

Following Tuck's (1978) definition of the Lamoka/Sylvan/Squibnocket complexes of central and southern New York and New England as the "Mast Forest Archaic," Snow (1980:226) proposed that we designate the Laurentian complex and related assemblages in northern New England and the St. Lawrence drainage as the "Lake Forest Archaic." As Snow described them, these two complexes coexisted, but each was more common within a particular geographic region. This scheme supposes that there was a "marginal belt of tension between the two coeval zones that persisted throughout the Late Archaic" (Snow 1980:227).

Site density increased relative to the preceding Middle Archaic, although there is no substantial shift in site location (Bunker 1988:11). The subsistence base of the Mast Forest tradition probably consisted of a generalized or diffuse adaptation (Dincauze 1974, 1975). Although white-tailed deer were a major source of food during the Mast Forest Archaic, these were supplemented by a broad range of vegetal foods, particularly nuts, and a broad range of finfish and shellfish resources. Evidence of technological innovations, such as weirs and nets, first appeared in the Late Archaic. Extensive salt marshes developed along the coast and at river mouths, providing a stable environment for increased exploitation of shellfish. Population of coastal areas appears to have increased dramatically at this time, particularly near the end of the Late Archaic period. Sites dating to the Late Archaic have been found throughout the Lakes Region and the Merrimack River drainage, as well as in the lower Androscoggin Valley. Carini (1994:IX-9) categorized these into "large base camps, small seasonal camps, and both large and small specialized resource procurement stations."

The end of the Archaic has also been commonly called the "Transitional," in reference to its presumed transitional status between the Archaic and Woodland periods. Since research continues to indicate that there is actually a great deal of cultural and biological continuity between the Archaic and the Woodland periods, Snow (1980:235) has suggested that the label "Terminal Archaic" is more appropriate.

As Snow defined it, the hallmark of the early part of the Terminal Archaic is the Susquehanna tradition of broad-stemmed projectile points and their associated assemblages. These points include several regional varieties, including the Genesee, Perkiomen, Snook Kill, and Susquehanna Broad types in New York. This Susquehanna tradition of broad-stemmed projectile points is analogous to Coe's (1964) Savannah River type from the southeastern United States. Characteristics of the Susquehanna tradition include a marked preference for a riverine

adaptation and a predilection for the fine-grained lithic resources of the Piedmont province, including rhyolite, felsite, argillite, and slate (Dincauze 1975:27; Turnbaugh 1975:54).

The latter portion of the Terminal Archaic period is marked by the appearance of narrow, tapered Orient Fishtail projectile points. Named for the type locations at Orient Point on eastern Long Island, Orient Fishtail points tend to be found on Long Island, in the Hudson Valley, and in southern New England (Ritchie 1971).

A marked increase in ritualistic behavior is also a feature of the Terminal Archaic cultures. Red ochre cremation burials with an assortment of grave goods are common from sites of this period in northern Massachusetts, and a cremation burial containing a broad-bladed point was excavated from the Litchfield Site, southeast of the current project (Bunker 1988).

Another hallmark of the Terminal Archaic is the appearance of steatite (soapstone) cooking vessels toward the end of the Susquehanna tradition (which continued throughout the Orient tradition). The presence of these large steatite vessels suggests that "the people who made, traded, and used [them] had reached a point in the evolution of their settlement and subsistence systems where the use of heavy cooking vessels was advantageous" (Snow 1980:240). This implies that these people lived in more sedentary settlements, utilizing foodstuffs that required long processing with heat.

3.1.3 WOODLAND PERIOD (CIRCA 2500–300 B.P.)

The Early Woodland period in much of the Northeast is represented by the Meadowood phase, with its distinctive, thin, side-notched projectile points and the first widespread appearance of ceramic vessels. This pottery, which has been given the type name Vinette I, appears on some Terminal Archaic sites, but did not become common until the Meadowood phase. The presence of pottery has long been one of the key defining attributes to separate sites of the Woodland period from those of the Archaic, in the absence of radiocarbon dates or chronologically distinctive stone artifacts. In addition to Meadowood projectile points, Adena, Rossville, and Lagoon points are also associated with this time period. Rossville and Lagoon points are particularly common on Early Woodland sites in the coastal areas of southern New England and Long Island Sound.

Early Woodland cultures in New England show considerable variation from the patterns seen in central and western New York. Sites in the latter regions show much greater participation in widespread trade networks that extended from the Gulf of Mexico to the Great Lakes. Exotic seashells, distinctive types of stone, and native metals like copper and lead moved between the far-flung reaches of the network. This trade network was also associated with an elaborate mortuary ceremonialism that included burying many of the exotic traded items in graves with the dead. The presumed core of this system was the Adena tradition of the Ohio River drainage, to which numerous elaborate sites with well-stocked graves have been attributed.

Adena/Middlesex-related burial sites have been found as far east as New England and the Maritime provinces, where they appear to be most common in the St. Lawrence and Connecticut River drainages. Cemetery sites near Lake Champlain and in New Brunswick have yielded a

wide variety of objects associated with this complex, such as blocked-end smoking pipes, copper and shell ornaments, as well as stone tools from distant sources, such as Indiana, Ohio, Ontario, and Quebec.

Throughout the Northeast, Early Woodland habitation sites are generally less common than the cemetery site, which has skewed the picture of the pre-contact lifestyles for this period. Many Northeastern Early Woodland burial sites actually predate classic Adena in Ohio, and it is likely that the Early Woodland manifestations in this region represent a complex interplay of traditions. Early ceramic vessels tend to be thin and grit tempered. Settlement patterns, at least in the earliest portion of the Woodland period, exhibit little variation from preceding Archaic patterns (Kenyon and McDowell 1983:21).

By the time of the Middle Woodland period, significant changes in subsistence practices began to appear in much of eastern North America. The use of plant foods started to intensify, and the cultivation of domesticated plants spread into the region between 1500 and 1000 B.P. This was often accompanied by increased sedentism in the settlement pattern, as people began to live in larger congregations for longer periods of time. Northern New England appears to have been situated on the climatic and cultural margins of plant cultivation, and it is still not clear how extensive a role domesticated plants played in the late pre-contact subsistence strategy. Seasonal shifts in settlement and subsistence may have characterized much of eastern New England. Inhabitants may have alternated between coastal resources in the fall, winter, and spring, and interior resources during the summer months (Bourque 1973; Snow 1980:301). Settlements in the later Woodland appear to have been localized, and there is no evidence for long-distance trade until the arrival of Europeans (Snow 1980:319), with the possible exception of lithic raw material. A slow trend toward population nucleation and increased sedentism characterizes the Woodland period, especially near the coast and along estuary heads (Lavin 1988:110, 114).

Local quartz was commonly utilized for stone tools throughout the Woodland period, but non-local materials, such as jasper and chalcedony, were also used. The earliest Middle Woodland point types include Fox Creek and Jack's Reef, and triangular Levanna points began to be used circa A.D. 800–1000. Near the end of the Late Woodland period, smaller Madison triangular points became common. At approximately the same time, the ceramic technology shifted from elongated, thick-walled vessels to globular, thin-walled vessels. The shoulders and collars of these vessels were often incised and appliquéd with elaborate decorations.

The late pre-contact and early contact period native inhabitants of northern New Hampshire belonged to the Algonkian culture, which encompassed much of the Northeast beyond the Iroquoian tribes of New York and the St. Lawrence River. European explorers made contact with the natives in the New Hampshire coastal region in the early seventeenth century. In the first few decades of the seventeenth century, European settlement of the coastal region began, and the diseases they brought with them decimated much of the native population. Most of the survivors of the waves of epidemics moved west and north, and were combined and absorbed with other refugee groups in Canada, western Massachusetts, and eastern New York.

3.2 Historic Background

3.2.1 CONCORD

King Charles I initially granted the territory that would become Concord, New Hampshire, to the Massachusetts Bay Colony in 1629 (Lyford 1903:95). However, the first settlement in the region did not occur until 1695, when Judge Samuel Sewell established a farm in the region under a grant from Governor John Endicott of Massachusetts. Unfortunately, the validity of the grant came into question as New Hampshire had become an independent colony in 1679 and also laid claim to the territory (Lyford 1903:99). Competing claims for the territory between Massachusetts and New Hampshire plagued the region though the end of the century. Additionally, a series of bloody wars with the Native American inhabitants of the region had raged along the frontier for much of the latter portion of the seventeenth century and well into the eighteenth century, which further frustrated settlement (Lyford 1903:101). Therefore, European settlers were not successful at establishing a foothold in the region that would become Concord until near the end of the first quarter of the eighteenth century.

In January 1725, the colony of Massachusetts Bay granted the parcel of land upon which Concord now stands as the Penacook Plantation (named after the Native American tribe that inhabited the region or had prior to the aforementioned wars), despite continuing conflicting claims from New Hampshire (Lyford 1903:96–106). Captain Ebenezer Eastman and his cohorts settled this new land grant; the resulting settlement grew quickly, establishing a small sawmill and gristmill along Mill Brook, which provided the materials and food the growing settlement needed (Lyford 1903:121, 125–126). Over the next decade, the settlement known as the Penacook Plantation grew substantially, and in January 1734, it was incorporated as a town to be known thereafter as Rumford (Lyford 1903: 136–137; Moore 1824:15). During the years to follow, the issue of the location of the boundary between New Hampshire and Massachusetts became hotly debated (Lyford 1903:152). Unable to come to an agreement among themselves, the two colonies set the dispute before the king, who redrew the boundary in 1740 (Lyford 1903:156). This new boundary line found the newly established Massachusetts township of Rumford cut off from Massachusetts and completely contained within the colony of New Hampshire (Lyford 1903:156–157). Boundary disputes soon arose between the town of Rumford and the New Hampshire town of Bow, located just to the south, whose charter from New Hampshire contained the same land given to Rumford by Massachusetts (Lyford 1903:156, 188–189). These bitter debates continued from 1749 all the way to 1771, when Rumford came to an agreement with the propitiators of Bow, in which they essentially repurchased the land they were living on (Lyford 1903:193, 215–216; Moore 1824:30). Despite the legal conflicts, in May 1765, Concord was created as a parish within Bow, though it was not until 1784 that the parish of Concord officially became a town (Lyford 1903:192, 222–223, 239; Bacon 1890:5; Moore 1824:44, 31–34).

The mid-eighteenth century saw a renewal of conflicts with the Native Americans and the French. Kings George's War, 1742–1749, pitted New England against the French colonies in nearby Canada (Lyford 1903:168). Men from the town of Rumford found themselves a part of the New Hampshire militia and engaged in numerous campaigns, including the siege at Louisburg (Lyford 1903:168–169). During this period, the town of Rumford established a

Garrison and erected fortifications to defend against attacks from the French and their native allies (Moore 1824:21). In 1746, a small force of Native Americans from St. Francis, Canada, attacked the town, resulting in the deaths of five citizens of Rumford (Lyford 1903:175–177; Moore 1824:23–25). Over the following years of the conflict, citizens of Rumford were constantly anxious about attack and had to be ever vigilant of assault, even while pursuing the most mundane agricultural chore, as enemies of the Crown were constantly moving through the region raiding or laying in ambush (Lyford 1903:182; Moore 1824:20, 27). Mercifully, peace came in 1748 with the Peace of Aix-la-Chapelle, and life in Rumford resumed a more normal pace (Lyford 1903:183). The peace in the colonies was short lived, however. In 1754, aggression between Britain and France renewed in the colonies, leading to the conflict that would become known as the French and Indian War (Lyford 1903:222). Once again, the people of Rumford had to look over their shoulders for fear of attack (Lyford 1903: 226). Throughout the ensuing conflict, armies and raiders from both sides roamed across Pennsylvania, New York, New England, and Canada; Rumford, being situated on the frontier, was always under threat (Lyford 1903:222–237).

In the latter half of the eighteenth century, Concord became a prosperous agrarian town. In 1790, the General Court removed to Concord because it was centrally located within the state. Some 18 years later, in 1808, it was officially selected to be the new capital of the state (Bacon 1890:6; Heald 2007:32). The moving of the capital to Concord brought new people, money and opportunities to the community. In order to better connect the new capital to the rest of the state, a plethora of new roads were devised. In 1794, the first stage line was established, with connections down to Boston (Lyford 1903:833). Six new turnpikes chartered between 1796 and 1809 conveyed people directly to Concord (Lyford 1903:833). However, the situation of the town above a series of large waterfalls in the Merrimack River prevented it from shipping large amounts of freight downstream to profitable markets like Boston. These navigational impediments isolated Concord and stifled the growth of industry. However, in 1807, Samuel Blodgett completed a canal lock around Amoskeag Falls to the south; he opened up the Merrimack River for Concord, eventually connecting them to the newly established Middlesex Canal (Mower 1991; Lyford 1903:834). Blodgett's lock around Amoskeag Falls opened Concord up to river commerce with towns all the way down to Boston. When the first regular freight ship made its way up through the newly completed Middlesex Canal to Concord in June 1815, everything changed, as there were suddenly more economic opportunities and markets available (Bacon 1890:6; Mower 1991; Lyford 1903:836). The growing city of Boston required raw material that the frontier towns along the Merrimack, including Concord, could provide. Timber, foodstuffs, and building materials like granite were shipped downstream from Concord through the canals to Boston. In return, finished goods and exotic foodstuffs flowed back up river to Concord (Lyford 1903:836–837).

With the arrival of the Boston-Concord Railroad in the region in 1842, the future of Concord was again altered (Bacon 1890:6; Bouton 1875:17; Lyford 1903:838). The town was now just a two-hour ride away from Boston (Bacon 1890:27). This advance meant that people and goods could be moved even faster than they could by boat through the canals, which could at the time take up to a week to get to Boston (Bouton 1875:9). This eventually spelled the end of the Middlesex Canal, which ceased operation in 1851 (Mower 1991). As an increasing number of rail connections were made to Concord with the additions of the Concord and Montréal (1869) and

Northern Railroads, its importance as a transportation hub grew and the markets for its economic output drastically expanded (Heald 2007:25). As Concord became a major railroad hub, the various rail lines that passed through the towns set up rail yards, depots, and maintenance facilities, adding yet another type of commercial activity to the Concord economy (Bacon 1890:27). These rail facilities hastened the growth of local foundries, casting houses, and machine shops that produced parts and tools for the railroad (Bacon 1890:68). All of this growth caused the citizens of Concord to incorporate themselves as a city in 1853 (Bouton 1875:17). In the late nineteenth century, Concord—already a major railroad depot—became a stopover on the way to the summer getaways in the White Mountains, which the newly consolidated rail lines of the Boston-Maine had made even more accessible to earnest vacationers (Heald 2007: 25, 32).

In the first half of the nineteenth century, dozens of hotels and taverns emerged in downtown Concord, catering to the throngs of businessmen, travelers, diplomats, and politicians that now frequented the town. These establishments first emerged with the coming of the stage lines, but continued to service patrons throughout the nineteenth century (Lyford 1903:853–865). One such hotel was the Eagle Hotel, which began life in 1827 as the Eagle Coffee House, but was subsequently enlarged in 1832. This site was the scene of many balls and social events, and often plays were preformed within its halls for the entertainment of the community (Lyford 1903:861). Sadly, the Eagle Coffee House burned in 1851 (Lyford 1903:862). The Eagle Hotel rose from its ashes and was completed in 1852. This new hotel successfully catered to visitors to Concord throughout the nineteenth century and was expanded in 1890 (Eagle Investment Trust 1970; Lyford 1903:862). The Eagle Hotel continued to operate as a lodging house for travelers to Concord until 1961, when it closed for good (Eagle Investment Trust 1970).

During the course of the nineteenth century, Concord established a wide variety of industries. Several large cotton mill complexes were erected, including the Haley Manufacturing Company, Holden Manufacturing Company, and the Concord Manufacturing Company (Bacon 1890: 27; Bouton 1875:11–12). However, Concord's economy was not centered on cotton production. During this century, Concord was best known as the producers of fine coaches and wagons, starting with Abbot & Downing Company. Abbot & Downing Company produced all manner of coaches and wagons that were utilized on the east coast, but also produced the stage coaches operated by Wells Fargo on the western frontier. Additional companies—like Concord Coach, Concord Carriage Company, Concord Harness, and Concord Axle—all soon followed and flourished in Concord, making it a key location in the horse-drawn transportation industry (Bacon 1890: 27). Leather work became important to the economy, and in 1872, the Page Belting Company moved its operations to Concord (Bacon 1890:26; Bouton 1875:13). The New England Granite Company found its home in Concord and from there distributed its stone throughout the northeast, where it has found its way into countless buildings across the country (Bacon 1890:27; Bouton 1875:13). Furniture making became a large portion of the economy in the nineteenth century (Bacon 1890: 27). Even the production of musical instruments became important to the economy when the Prescott Organ Company established itself in Concord (Bacon 1890:27; Bouton 1875:13). While other industrial towns in New Hampshire were focusing on cotton, Concord took a more diversified approach, and while cotton played a role, it was far from the dominant industry.

At the start of the twentieth century, Concord's economy began to change once more. The cotton production industry—a facet of Concord's economy—failed after World War I as the cotton industry moved to the South, eliminating the transportation cost for raw materials. The cost of importing raw material to the mills for northern manufactures was exorbitant compared to its ready availability in the South. Southern mills could therefore produce the same product for considerably less than their northern counterparts. Confronted with the new economic reality, northern mills could no longer compete (Singleton 1997:132). Many of the cotton mills in Concord closed during this first quarter of the twentieth century. As the automobile came to replace the horse-drawn wagon and stage coach, those industries too faltered and passed into history.

During this time, Concord began to lean more heavily upon the railroad as the cornerstone of their economy, a dependence that had begun in earnest near the close of the nineteenth century. Industries like granite quarrying remained unaffected and persist to this day. The twentieth century also saw the introduction of the insurance industry to Concord, which remains a major part of its modern economy (New Hampshire Employment Security 2013). As the automobile came to prominence, replacing the rail lines as the dominant method of personal transportation, those industries associated with the railroads atrophied and disappeared. This could have been detrimental to Concord's economy, but even as these railroad-associated manufacturing industries were vanishing, new industrial manufacturing concerns began moving in to take their place. In the 1960s, the Sprague Electric Company began creating semi-conductors for use in electronics in Concord, creating a new industrial opportunity and establishing a foothold for Concord in the newly developing electronics industry (Lojek 2007:205). While the insurance and electronics industry remain important to Concord today, they have been eclipsed by economic opportunities in the government, education, retail, and healthcare industries that have become the driving force of the Concord economy in the twenty-first century (New Hampshire Employment Security 2013).

3.2.2 MANCHESTER

The initial influx of European settlers into the region that would become Manchester came via settlers following the extant Native American trails north through the Merrimack Valley from Massachusetts, traveling as far north as Amoskeag Falls, the site of well-known and long-used native fishing grounds. During the late seventeenth century, the first wave of Euro-American settlers were drawn to the area around Amoskeag Falls by the promise of rich fishing grounds. They soon discovered that the Merrimack River's plentiful floodplains and upland terraces offered further agricultural opportunities. The resulting settlement of the region occurred as the area was divided into farmsteads, resulting in the first real permanent settlements in the area around the dawn of the eighteenth century (Willey 1895). As settlement of the area grew, entrepreneuring settlers also availed themselves of the numerous streams and creeks feeding into the Merrimack River to power small mills. In fact, the region was so rich in resources, it became the subject of numerous land disputes between settlers and the Crown, the local Penacook Native Americans, as well as other colonies, like Massachusetts—all of whom debated ownership though much of the later portion of the seventeenth century and throughout the first half of the eighteenth century (Anonymous 1875; Blood 1948:35; Browne 1901:7).

The area that became Manchester was initially dubbed Nutfield because of the great forests of chestnut trees that blanket the eastern bank of the Merrimack River (Hazlett 1915; Willey 1896). It was not until 1722, however, that the area received an official land grant from the provincial governor of New Hampshire, who renamed the region Londonderry. This grant was secured by a collective of 16 Scottish families who had arrived in the region as early as 1719 (Anonymous 1961; Browne 1901; Hazlett 1915; Bunker 1997:7). This same year, John Goffe, Jr., and members of his extended family established a settlement near the place where the Cohas Brook joins the Merrimack (Clarke 1875; Potter 1856). An additional wave of English settlers populated the area to the north near Amoskeag Falls (Clarke 1875). The expanse of land between the Cohas Brook and Amoskeag Falls was principally used for grazing cattle and was known as Derry's Field. In 1751, a new town charter was established in this location, and this former pasture land became the town of Derryfield, the forerunner of Manchester City.

During this early period of settlement, the economy of the area was firmly settled around agriculture. However, as settlement increased in the early part of the eighteenth century, the demand for timber and grain processing grew. This new need triggered the creation of a string of saw and gristmills along the Cohas Brook, the fast-flowing waters of which provided ample waterpower for the mill operations. These milling ventures were spearheaded by settlers like Ephraim Hildreth (circa 1735) and John Goffe (circa 1749) (Potter 1856:657–658; Bunker 1997:9). As these mills grew in importance, roads along the Merrimack River and Cohas Brook were established to help facilitate the flow of finished goods to the community. Additionally, a ferry was established near the mouth of the Cohas Brook, enabling the speedy transfer of goods and people across the Merrimac to the neighboring community of Bedford. This increased mobility opened up larger markets for the mill goods and inspired others to invest in industry. At the dawn of the nineteenth century, the fledgling Middlesex Canal was beginning to provide cheap, efficient river traffic down the Merrimack River to Boston, but the great Amoskeag Falls remained an impediment. In 1807, as discussed above, the visionary Samuel Blodgett removed this final hurdle when he opened the Amoskeag Canal, the first canal lock around Amoskeag Falls (Mower 1991). These infrastructure improvements led to the creation of large industrial mills in Derryfield. In 1809, Benjamin Pritchard, Robert Stevens, and Ephraim David established a cotton spinning mill along the western bank of the Merrimack, near Amoskeag Falls (Potter 1856:545). Additional mills soon followed along the eastern bank. After a rocky start, the Amoskeag Cotton Woolen Manufacturing Company (the company started by Pritchard and his associates) changed hands in 1831 and became known as the Amoskeag Manufacturing Company, which quickly improved, diversified, and modernized operations.

In 1810, around the same time as the first mills were being established along the Merrimack, Derryfield was rechristened Manchester after the first industrial town in England, whose model of industrial prosperity the residents of Derryfield (like Samuel Blodgett) hoped to emulate (Potter 1856:543). As the mills grew, they attracted more people to work in them, mostly from French Canada to the north, and the need for housing boomed. In a few short years following the chartering of the new Amoskeag Manufacturing Company, the town of Manchester had been utterly transformed. The company had created a new wing dam around the falls, increasing its power output, and after purchasing most of the eastern shore near the falls, had built two new canals capable of handling increased river traffic (Potter 1856:551–552). In 1838, a new mill corporation, the Stark Mills, established the first cotton mill building on the east bank of the

Merrimack (Potter 1856:565). The mill was a success and its initial building, Stark Mill No. 1, was expanded in 1843. Eventually a second building was added, Stark Mill No. 2, in 1847.

This rapid expansion of Manchester's industry drew even more people to work in the mills, so in 1839, the Amoskeag Manufacturing Company took it upon themselves to create a company town surrounding the mills and centered on the newly created Elm Street, which was to serve as the new main road for the town (Potter 1856:593). This town was situated on the eastern bank of the Merrimack to the east of the canals. Its placement necessitated a means across the river for the workers to access the mills. Thus, in 1840, the Granite Street Bridge was built. It remained a toll bridge until 1847, when Granite Street was laid out as a public highway (Potter 1856:711). As industry and settlement in the area continued to grow, so too did Manchester. By 1846, the town of Manchester had grown into a city and was incorporated as such in June of that year (Potter 1856:629).

In 1815, the completion of the Middlesex Canal system opened the river for barge traffic between Concord and Lowell, Massachusetts. Until its abandonment in 1851, the canal linked the Derryfield area with commercial centers, such as Nashua and the industrial towns of northern Massachusetts, greatly increasing its export capacity and expanding the regional market (Mower 1991). While the canals were increasing the mobility of freight, newly constructed roads were enhancing the mobility of people. The 1805 charter of the Middlesex Turnpike, which largely paralleled the canal system along the Merrimack, provided road access all the way down to Boston. After a contentious debate over its creation, the people of Manchester finally agreed to the establishment of the Mammoth Road, a stage line that ran daily stages between Concord and Boston (Willey 1896: 66–67). However, with the establishment of the Concord and Montreal Railroad in 1842, these roads lost all importance and quickly vanished into obscurity (Willey 1896; Mower 1991). This initial railway was so successful that additional railways like the Manchester and Lawrence Railroad (now known as Boston and Maine Railroad) were established just seven years later. The coming of the railway provided fast and efficient transportation of goods and people to metropolitan cities like Boston. These railways proved too efficient for many of the other forms of transportation, completely overshadowing the established roads and canals (Mower 1991).

The combination of efficient transportation and a strong manufacturing base saw the city of Manchester flourish throughout the nineteenth century and into the first quarter of the twentieth century. In the latter half of the nineteenth century, the Amoskeag Manufacturing Company diversified from textiles to railroad engines, fire trucks, and weapons manufacture with the addition of the Amoskeag Foundry. The 1920s saw the beginning of an economic downturn in response to the end of World War I. During this period, the cotton industry had begun moving to the South. The cost of importing raw material to the mills for northern manufactures was exorbitant compared to those in the South, who had a ready supply on their doorsteps. Southern mills could therefore produce the same product for considerably less than their northern counterparts; as a result, they flooded the market, driving down prices (Hareven and Langenbach 1995:302). Demand for fabric and linens plummeted and the northern mills began to suffer (Singleton 1997:132; Hareven and Langenbach 1995:302). Confronted with the new economic reality, many northern mills could no longer compete and folded (Hareven and Langenbach 1995:336). To combat the falling profits, the owners of the Amoskeag Manufacturing Company

cut the wages and increased the hours of their employees, an action which led to massive labor strikes (Hareven and Langenbach 1995:336). These events undermined not just management-labor relations, but also alienated customers, further exacerbating the problem. With the stock market crash in 1929, the labor tensions were further enflamed, leading to violent strikes in 1933 and 1934. In the wake of these difficulties, the mills began a gradual decline, and in 1935–1936, the Amoskeag Manufacturing Company, once the heart of the city, went bankrupt and was shuttered.

After the demise of the mills in Manchester, their industrial buildings were carved up and occupied by smaller manufacturing concerns throughout much of the twentieth century. In the second part of the twentieth century, the abandoned mills became the home of electronics manufactures, metal-working facilities, plastics manufacturers, and machine builders, helping to restore the industrial base of Manchester. Today, old mill buildings still remain a key feature of the landscape, but are now home to small businesses, hospitals, universities, and restaurants that provide economic opportunity for the residents of Manchester City.

3.2.3 NASHUA

The story of Nashua, New Hampshire, is weirdly also partly the story of Dunstable, Massachusetts. This may seem like an odd assertion, until it is acknowledged that during the earliest period of European settlement in the region, the section of New Hampshire in question was at the time considered to be Massachusetts, as the colony of New Hampshire had yet to be conceived. Early forays into the region were largely limited to ventures designed to carry on trade with the native populations of the Merrimack Valley. One such venture occurred in 1665 and was executed by John Cromwell, a fur trader who established a trading post along the Merrimac near a small falls. This experiment did not endure and was subsequently abandoned (Fox 1846:21). In 1673, the land where Nashua now lies was part of a 200-square-mile land grant made to Edward Tyng (Fox 1846:16–17). Tyng established the town of Dunstable (named after his native town of Dunstable, England) near the confluence of the Merrimack and Nashua Rivers (the site of modern-day Nashua City).

Starting in 1675, the region was the scene of a bloody conflict between the native peoples of New England and European settlers (Fox 1846:28). This conflict, which would become known as King Philips War (King Philip was the European name given to Metacomet, the Grand Sachem of the Wampanoag), raged for three years. During the conflict, Metacomet and his allies destroyed neighboring settlements, including the towns of Chelmsford and Groton, which were contained within the same 200-square-mile grant (Fox 1846:28; Peters 2006:8). The Penacook tribe of the Merrimack Valley had sided with Metacomet initially, but made a separate peace with the colonists. By this point, the conflict had greatly reduced their numbers and lost them a great deal of territory, and many fled to Canada (Fox 1846:21). While the discord had caused many of the Dunstable colonists to flee, the cessation of fighting in 1678 prompted many to return, and the town grew once more (Fox 1846:37). This resurgence was short lived. Due to competing land claims between the colonial powers in Europe—namely Britain and France—and native populations in the Americas, the region was the stage for an additional two wars: King William's War and Queen Anne's War. (In the Americas, both groups had their native allies, though the French garnered more support from native populations in New England). During the

late seventeenth and early eighteenth centuries, Dunstable was a frontier town on the frontlines of these conflicts and was frequently garrisoned (Fox 1846:65–68, 82, 103). While the citizens of Dunstable occasionally fell victim to the ravages of such conflicts, the town itself miraculously survived, unlike other similar settlements that were continually attacked and destroyed (Fox 1846:65). Still, the constant fighting and fear of Indian attack caused the settlement of the area to stagnate until the beginning of the eighteenth century (Fox 1846:68).

During the latter portion of the seventeenth century and into the early part of the eighteenth century, many land disputes between competing charters and land grants occurred between the established colony of Massachusetts and the newly formed colony of New Hampshire. For much of this time, both colonies laid claim to the town of Dunstable and its surrounding territory, part of the original Tyng grant. This debate continued for well over 50 years—until 1741, when the boundary between the two rival colonies was settled (Stearns 1986:v; Fox 1846:147; Peters 2006:8). This decision split the original Tyng grant in half, with the northern portion and town of Dunstable going to New Hampshire, and the southern portion of Dunstable going to Massachusetts (Fox 1846:147; Peters 2006:8). It was during this time that Massachusetts created the municipality of Tyngsborough out of part of the southern portion of their new territory. Thus, this boundary settlement led to the creation of Dunstable and Tyngsborough in Massachusetts and the town of Dunstable in New Hampshire, which was formally incorporated in 1746 (Fox 1846:150).

The second half of the eighteenth century saw two additional wars: the French and Indian War and the American Revolution. Men from New Hampshire participated in these conflicts, but the fighting occurred elsewhere (Fox 1846:159–168). The first quarter of the nineteenth century saw the continued growth of Dunstable; the population had rapidly expanded throughout the eighteenth century and was now close to 900 people (Fox 1846: 193). It was during this period that Dunstable established its first post office, got its first stage line (Amherst-Boston), and established several taverns (Fox 1846: 193). By 1804, the town had been connected to Boston via the newly opened Middlesex Canal. This new connection stimulated the fledgling economy of Dustable (Fox 1846:196). The variety of industries in the town expanded; new saw and gristmills were built, as well as additional stores and taverns to handle the new flow of goods and travelers brought to the area via the canal (Fox 1846:198).

The dawn of the nineteenth century, however, brought big changes to the area. In 1802, the Middlesex Canal came through the area, connecting Dunstable to Boston via river and enabling the bulk exchange of goods. Suddenly, subsistence agriculture was not the only way to make a living. The growing city of Boston required raw material that the frontier towns along the Merrimack, including Dunstable, could provide. Timber, foodstuffs, and building materials flowed down to Boston from Dunstable, and finished goods flowed back up river to Dunstable. The local economy diversified rapidly, as new business ventures emerged to fill the demand for new goods. The town grew and the economy expanded from a local to regional scale. Then, in 1821, in Lowell, Massachusetts, a large cotton mill was established and brought great prosperity to the town. Seeing the success of the operations at Lowell, an environmental setting similar to that of Dunstable, investors began to plan a similar enterprise (Fox 1846:198). The result of this planning was the Nashua Manufacturing Company, established in 1823 by Daniel Abbot and other investors from Dunstable (Steinberg 2004:80; Fox 1846:199; Peters 2006:13; Charlton

1856:309). Though not an instant success, the Nashua Manufacturing Company persevered and undertook to harness as much waterpower as they could to provide for the future operations of their mills. The result was the Nashua Power Canal, essentially a giant mill race, which carried high-velocity water three miles downstream from Mine Falls, providing the torrent of waterpower needed to operate the ever-expanding mills (Steinberg 2004:78, 81; Fox 1846:200).

The Indian Head Company, another milling operation, opened downstream in 1826, taking full advantage of the improved waterpower from the Nashua Manufacturing Company (Steinberg 2004:81; Fox 1846:200; Charlton 1856:309). This corporation was short-lived and was bought out by investors from Boston just two years later. These investors, known as the Boston Associates, poured capital into the Indian Head Mill, revitalizing and modernizing it. The result was a new company known as the Jackson Manufacturing Company (Steinberg 2004:82, Fox 1846:205).

After a rocky start, the Nashua Manufacturing Company found its feet, and by 1836 had built and was operating three large cotton mills (Peters 2006:12; Steinberg 2004:80). These new mills created employment opportunities that drew people to Dunstable. This influx of workers drastically increased the population of the town, which by 1830 numbered 2,417 persons (Fox 1846:206). The draw of the mills was strong; as they expanded, so did the town. In the seven years between 1830 and 1837, the population nearly tripled (Fox 1846:207). To meet the needs of their workforce, the companies set about planning a town for their workers surrounding the mills, complete with housing, schools, and churches (Peters 2006:59). This neighborhood became known as Nashua Village (Fox 1846:202–203). Having developed a new identity as an industrial town, the citizens of Dunstable elected on the eve of 1837 to rename the town Nashua, a name that has persisted ever since (Fox 1846:209; Peters 2006:8).

By the 1830s, Nashua was a booming industrial town where new advances were readily embraced. In 1836, the town embraced a new advance in transportation technology, the railroad; by 1838, it had completed its first line connecting it to Lowell, Massachusetts (Fox 1846:207; Wallace and Mausolf 2001:19). The success of this rail line prompted the establishment of five more rail connections, making Nashua an important transportation hub (Fox 1846:208; Peters 2006:75; Charlton 1856:311-312). The coming of the rail lines had signed the death warrant of the Middlesex Canal, which could not compete with the speed of the railroads (Mower 1991; Wallace and Mausolf 2001:19). By the mid-1850s, the canals had been abandoned (Mower 1991). The success of the railroads opened up even more markets to the already bustling industries in Nashua and created new industrial opportunities. The industries of Nashua diversified again, and while still largely dependent on cotton mills, the city also began to work in iron, paper, leather, and machinery (Fox 1846:210–212, 214; Charlton 1856:309). Nashua also developed industries that serviced the railroads, including foundries and repair yards (Wallace and Mausolf 2001:26).

Nashua became not only an industrial powerhouse, but a crucial economic hub. Despite its growth and prosperity, the town of Nashua continued to have boundary problems. In 1842, the north section of the town, situated above the Nashua River, broke away and formed a new town called Nashville as a result of a disagreement over the placement of the town hall (Fox 1846:213; Peters 2006:8; Charlton 1856:309). The hurt feelings and division persisted for 11 years, until

the two "towns" buried the hatchet and joined together to form the city of Nashua. The charter for the city was created in 1853 (Steinberg 2004:216; Peters 2006:8).

The growth of Nashua had prompted many waves of immigration throughout the nineteenth century. The initial immigrants were Irish and French-Canadians (Québécois) who flooded to the area in search of work prior to the Civil War (Trustees of the Hunt Memorial Building 1999; Federal Writers Project of the Works Progress Administration for the State of New Hampshire 1938:75–76). Wars and social upheaval in Europe during the second half of the nineteenth century prompted a second wave of immigration. During this time, the established Irish and French-Canadian ethnic communities were joined by waves of mass immigration from the Mediterranean and Eastern Europe (Trustees of the Hunt Memorial Building 1999; Federal Writers Project of the Works Progress Administration for the State of New Hampshire 1938:76). Mill towns like Nashua became much more ethnically diverse, as the waves of immigration enriched the local cultural/ethnic tapestry and new ethnic neighborhoods were established. These new communities included people from Greece, Lithuania, Italy, Poland, Hungary, Austria, Germany, Bohemia, and Russia (Federal Writers Project of the Works Progress Administration for the State of New Hampshire 1938:76). These immigrants brought with them their traditions, customs, and food.

During the nineteenth century, other mills had established themselves along the Merrimack in Nashua. However, the Nashua Manufacturing Company outperformed them all, and eventually came to purchase some of its smaller rivals, like the Jackson Company, Indian Head Mills, Tremont Mills, and Suffolk Mills. These acquisitions further expanded the company colossus, firmly ensconcing it as the core of the economy in Nashua. The 1920s saw the beginning of an economic downturn in response to the end of World War I. As discussed in the above section on Manchester's history, the cotton industry had begun moving to the South during this period. The South's ready supply of cotton eliminated the costs of shipping raw material to the north. While producing the same product for considerably less, Southern mills could flood the market and drive down prices (Hareven and Langenbach 1995:302). Confronted with a significant drop in the demand for fabric and linens, and the new economic reality that went with it, many northern mills closed (Singleton 1997:132; Hareven and Langenbach 1995:302, 336). Remarkably, the Nashua Manufacturing Company persisted through World War II, likely due to its more diversified business model. However, the company was purchased by Textron, Inc., in 1945, and only two years later, the mills of the Nashua Manufacturing Company were shuttered (Chomsky 2008:104).

The period following the closing of the mills in Nashua was dark, but mercifully short lived. With one of the primary employers in the city suddenly gone, unemployment was rampant for a few years. The Nashua New Hampshire Foundation purchased the abandoned mills from Textron in 1953 and attempted to attract new industries to the area (Chomsky 2008:104). Luckily for the city of Nashua, their existing infrastructure and available workforce was attractive to burgeoning new industries, including electronics, plastic manufacture, paper production, as well as electric and steel industries (O'Connell 2013:218). Perhaps the most important new industry, however, arrived in 1952. In that year, Sanders Associates moved into the vacant Jackson mill complex (Trustees of the Hunt Memorial Building 1999). This circuit board manufacturer emerged as an important player in the Cold War defense economy and

became integral to the development of the defense industry, space program, and early computer industry (O'Connell 2013:218). Eventually, the Sanders Associates became part of Lockheed Martin, and eventually part of BAE Systems Electronics & Integrated Solutions. As these new industries renewed the city's economy and provided more economics opportunities, the city continued to grow. With the popularization of the automobile in the postwar era, a number of suburbs emerged around Nashua. These new settlements in turn provided new economic opportunities in the form of retail outlets to and shopping centers that further diversified and bolstered the city's economy (Trustees of the Hunt Memorial Building 1999; O'Connell 2013:218). Additionally, the construction of major highways over the second half of the twentieth century once again provided economic opportunities that were just a short commute away, and drew Nashua closer to other neighboring cities like Lowell and Boston once more (O'Connell 2013:217–218). These areas had also been undergoing similar transitions and had developed similar electronics and computer-based industries. Today, Nashua is a powerful player in the nation's northeast electronics industry, as part of the greater Boston high-tech corridor.

5.0 Phase IA Field Reconnaissance

5.1 Concord

5.1.1 STICKNEY AVE

URS conducted the Phase IA field reconnaissance for the proposed Stickney Avenue train station and parking area in Concord on March 24, 2014. Stickney Avenue is a small street that parallels I-293 and dead ends at a bus depot opposite a small neighborhood. The proposed work at this location consists of the creation of an at-grade train platform and an adjacent parking area, largely situated within an extant NHDOT office facility and its associated support buildings and garages. The entire proposed APE was pedestrian surveyed and photo-documented. The remainder of the APE is situated along an extant railroad line and its associated bed, located immediately to the west of the NHDOT parking lot (Figure 24). Field reconnaissance revealed that the majority of the proposed parking facility exists within an area that is already paved and used for parking, but is currently gated and not open to the public. Within this gated parking area are several maintenance buildings associated with the main NHDOT office complex, situated along the western edge of Stickney Avenue, facing I-293 (Figure 25, Figure 26, Figure 27, Figure 28, Figure 29, and Figure 30). As macadam capped the soil in this area, it was impossible to visually inspect the area for signs of cultural material. The area of the proposed train station, along the western edge of the extant parking lot, poses a similar impediment to visual reconnaissance. The proposed APE for the train station is situated within an extant railroad bed and, as such, is capped by a thick layer of bluestone gravel that has raised the ground surface in the area by several feet. As the bluestone railroad bed blankets the majority of the APE, it was impossible to see any soils and ascertain the condition of the subsurface stratigraphy (Figure 31, Figure 32, and Figure 33). However, in a narrow corridor between the fence to the parking lot and the railroad bed, there is a narrow strip of exposed soil that also functions as a power line right of way (ROW) (Figure 34and Figure 35). Examination of this soil demonstrated that it is riddled with debris and appears to be fill soil. This soil was likely imported or moved to the site during the construction/grading for the adjacent railroad bed or during the construction of the power line ROW.

5.2 Manchester

5.2.1 SPRING STREET STATION

URS conducted the Phase IA field reconnaissance for the proposed Spring Street train station in Manchester on March 24, 2014. The proposed station is oriented parallel to Canal Street in downtown Manchester and is bounded to the south by Spring Street and to the north by Dow Street (Figure 36). The proposed APE is located in the former industrial heart of Manchester, which in recent years has been adaptively reused and transformed into a college campus and a network of commercial outlets and dining establishments. Field reconnaissance revealed that within the APE, immediately to the west of the extant rail bed, is situated a large parking area built to service the University of New Hampshire, which has taken up residence in the plethora of nineteenth-century mill buildings that line the Merrimack in downtown Manchester. Opposite the proposed platform on the eastern side of Canal Street is a large public parking garage, and to

the southeast of the Spring Street rail crossing is another large public parking facility (Figure 37 and Figure 38). The APE of the proposed rail platform in this area is situated between the extant university parking area to the west and Canal Street to the east. The bulk of the APE is situated inside an existing rail bed comprised of several feet of highly compacted crushed stone ballast that has raised the ground level by several feet. The rail bed runs underneath the Bridge Street overpass, which towers nearly 50 feet above the location (Figure 39 and Figure 40). To the east of the rail bed is an overgrown gravel-lined drainage ditch, which is the only unpaved surface within the APE or its adjacent area (Figure 41). Attempts to illicit information about the soil profile of the APE through examination of the soil in the drainage ditch was hindered by a layer of gravel and fill, which prevented the collection of any deep samples.

5.2.2 GRANITE STREET STATION

URS conducted the Phase IA field reconnaissance for the proposed Granite Street train station in Manchester on March 24, 2014. This proposed station area is bounded to the north by Granite Street, to the east by Canal Street, to the west by Bedford Street, and to the south by a large industrial complex; it consists of a small at-grade platform and an associated parking area (Figure 42). Field reconnaissance failed to reveal any evidence of archaeological resources in this area. The APE is divided east-west by the existing rail line. To the northeast of the Granite Street and Canal Street intersection, there is an extant parking garage that is hoped to provide parking for the proposed station (Figure 43). The existing rail line and its railroad bed spans the entire distance between Bedford Street to the west and the existing parking lots and structures situated to the east of the tracks (Figure 44, Figure 45, Figure 46, and Figure 47). The proposed station platform is to be situated within the existing railroad bed, butting up against existing structures like the adjacent bank, and making use of existing public parking areas (Figure 44, Figure 45, and Figure 46). The APE in this area is comprised of several paved parking lots and the existing railroad bed, all of which have capped the buried soils and prevented examination of them for evidence of cultural material. As a result, it was not possible to ascertain the nature of the buried substrata in this location and assess the archaeological sensitivity of those soils.

5.2.3 GRANITE STREET LAYOVER

URS conducted the Phase IA field reconnaissance for the proposed Granite Street rail siding in Manchester on March 24, 2014. The Granite Street Layover is a proposed location for overnight train storage and maintenance. It is located to the south of Granite Street, along South Commercial Street and Riverwalk Way, which define the western edge of the APE (Figure 48). Field reconnaissance failed to reveal any evidence of archaeological resources in this area. Field reconnaissance revealed that a steep change in elevation marks the eastern edge of the APE (Figure 49 and Figure 50). In most cases, this change in elevation corresponds with the start of back parking lots belonging to businesses located along Elm Street. A minor league baseball stadium is situated to the northwest of the northern extent of the proposed APE (Figure 51). The entire APE for this siding is covered in a thick layer of crushed stone ballast, which creates a long level rail bed (Figure 52, Figure 53, Figure 54, Figure 55, Figure 56, Figure 57, and Figure 58). This rail bed extends all the way to the eastern edge of the APE. The surface of the APE is marked by rail lines, both used and disused. This area was once a large railroad siding and is still used for that purpose on occasion (Figure 59). Although overgrown in some areas, the entire

ground surface of the APE is comprised of crushed stone ballast, which renders the soils of the APE inaccessible and prevented the assessment of its archaeological integrity and sensitivity (Figure 54).

5.2.4 CEMETERY LAYOVER

URS conducted the Phase IA field reconnaissance for the proposed Cemetery Layover in Manchester on March 24, 2014. The Cemetery Layover is a proposed location for overnight train storage and maintenance located along the eastern bank of Merrimack River, opposite Carthagina Island (Figure 60 and Figure 61). Field reconnaissance was conducted along the proposed layover, which has been designed to parallel the existing run of track within the existing rail bed. While at present only one track exists on the rail bed, there is evidence in the form of old rail ties that indicates that the rail bed once supported a secondary rail line. The terrain that comprises the APE in this area is long and flat, bounded to the east by forested floodplain that a quarter mile to the east climbs sharply up toward Pine Grove Cemetery. The western edge of the APE is bounded by a small access road that runs along the edge of the Merrimack River. Vestiges of the history of the railroad lined the extant rail bed in the form of telegraph poles, some of which remain standing. The ground within the APE is almost entirely comprised of extant railroad bed that is a raised and graded run of compacted crushed stone ballast (Figure 62, Figure 63, Figure 64, and Figure 65). The crushed stone ballast of the rail bed prevents the examination of the soil directly within the APE, but some inferences can be drawn from the surrounding areas. The soils to the east toward the cemetery are heavily waterlogged and are predominantly a wetland habitat (Figure 66). While outside the APE, the soil to the west of the rail line between the access road and the river does appear to have integrity and is consistent with the silty loam expected in a river floodplain (Figure 67). It should be noted that the presence of Carthagina Island near this location has increased the flow of the river and carved steep banks to the eastern edge of the Merrimack. As a result, there is a substantial drop between the edge of the bank and the surface of the river. What the effect of this erosion has had on buried cultural resources in the floodplain is unknown.

5.2.5 QUEEN CITY BRIDGE LAYOVER

URS conducted the Phase IA field reconnaissance for the proposed Granite Street rail siding in Manchester between March and July of 2014. The Queen City Bridge Layover is a proposed location for overnight train storage and maintenance. It is located immediately to the North of the Brown Ave. Wastewater Treatment Plant and to the south of the proposed Granite Street Layover (Figure 68). The southern portion of the APE runs beneath the Queen City Bridge and the APE is bounded to the north by the remains of a former rail yard to the west by the Merrimack River, and to the east by the current main line railroad. Field reconnaissance revealed evidence of a former structure, recently demolished, within the proposed APE along the eastern edge of the APE paralleling the railroad tracks. The demolition debris however appears to be modern in origin dating to the latter half of the 20th century. The ground surface in the area is largely flat having been graded in the past in association with the former structure (Figure 69). The majority of the APE is comprised of pavement, concrete and crushed stone ballast. In the area where the former structure was located lays a debris and fill-dirt pile which is somewhat grown over. To the west a thin ribbon of trees separates the APE from the Merrimack River. As

the soil in the area is all covered by extant caps it was not possible to examine the soils in this area.

5.2.6 WASTEWATER TREATMENT PLANT LAYOVER

URS conducted the Phase IA field reconnaissance for the proposed Wastewater Treatment Plant Layover in Manchester on March 24, 2014. The Wastewater Treatment Plant Layover is designed to be used for overnight train storage and maintenance, and is located near its namesake, the Manchester Wastewater Treatment Plant at 300 Winston Street. The plan is to construct four rail sidings to be used as layovers and a small maintenance building (Figure 70 and Figure 71). Field reconnaissance failed to reveal any evidence of archaeological resources in this area. The proposed construction area was pedestrian surveyed and photographed. This effort demonstrated that, with the exception of the proposed maintenance building, the APE is largely confined to the extant railroad corridor and railroad bed that exists between the wastewater treatment plant, which defines the western edge of the APE, and the series of modern industrial warehouses that define the eastern edge (Figure 72 and Figure 73). The APE is bounded to the north by the NH 101 overpass and is split into a northern and southern section by the Winston Road rail crossing, which enables emergency access to the wastewater treatment plant (Figure 74, Figure 75, and Figure 76). The entire APE, therefore, is comprised of a long, straight gravel rail bed defined by high security fences along its eastern and western edge. The entirety of the APE is blanketed in a thick layer of compacted crushed stone ballast and thus the soil within the APE was unavailable for examination (Figure 72, Figure 73, Figure 74, Figure 75, Figure 76, and Figure 77). The edge of the railroad bed was lined along its western flank by a series of disused telegraph poles that once serviced the rail line (Figure 77). These telegraph poles are the only visible cultural resource extant within the APE.

5.2.7 MHT AIRPORT-RAY WIECZOREK DRIVE STATION

URS conducted the Phase IA field reconnaissance for the proposed MHT Airport-Ray Wieczorek Drive station in Manchester on March 24, 2014. This station location is situated to provide commuter rail access to the Manchester-Boston Regional Airport, located to the northwest on the eastern bank of the Merrimack River. The proposed APE for this station is situated along the western bank of the Merrimack, adjacent to and underneath the Ray Wieczorek Drive Bridge across the Merrimack. The central portion of the station platform is slated to be placed underneath the newly constructed bridge, with a parking area along its northern flank (Figure 78). The majority of the proposed station falls within the existing railroad bed that extends more than 2 meters on either side of the existing track. This railroad bed is made of a raised berm of compacted crushed stone ballast several feet thick (Figure 79 and Figure 80). Due to the substantial nature of the railroad bed, it proved impossible to examine the soils that lay beneath, so its archaeological sensitivity and integrity remain undetermined. The area close to the bridge, which was constructed in 2013, is highly disturbed and the visible soils are a mix of fills and gravel (Figure 80). The area to the east of the track, which separates the railroad corridor from the Merrimack River, appears to be undisturbed floodplain that may retain integrity, but this area falls outside the project APE, so it was not examined.

5.3 Nashua

5.3.1 CROWN STREET

URS conducted the Phase IA field reconnaissance for the proposed Crown Street station in Nashua on March 24, 2014. This station location is situated to provide rail access to downtown Nashua. It is located along the western bank of the Merrimack River, just to the south of where the Nashua River joins the Merrimack. The construction plan calls for the construction of an at-grade platform and an expansive parking lot to the southwest of the existing track (Figure 81). The proposed platform location occupies a strip of railroad bed that sits in front of a disused warehouse building that lies just to the northwest of the Pan America rail yard. The APE for the platform location is oriented northwest to southeast, following the existing railroad bed. While wide and substantial within the APE, the rail bed fans out opposite the southern half of the abandoned warehouse and becomes even wider as it merges into the rail yard located immediately to the south (Figure 82 and Figure 83).

The portion of the APE designated as potential parking appears at first glance to be flat and level, although lower in elevation than the railroad bed. In some places, the ground surface appears to have been graded and paved already; upon closer examination, the reason for this becomes clear. The area has been leveled in the past because the entirety of the proposed parking facility is the basement/ground floor of a large industrial structure/s no longer standing here. Standing in the grassy field to the southwest of the train track, it becomes clear that the western section of the proposed parking area is a full story deeper in elevation relative to the eastern section, which indicates that the eastern section (the grassy area nearest the tracks) was likely a basement. This impression is reinforced by the vestiges of the walls remaining around the perimeter (Figure 84). The western portion of the APE, which comprises the upper section of the foundation complex, shows evidence of structural subdivisions for rooms that appear as concrete curbs or lines in the paved surface (Figure 85, Figure 86, and Figure 87). In addition to the structural subdivisions visible via examination of the exposed concrete floor, the ghost marks of the demolished structures can be seen on the extant wall of the adjacent building, which at one time they abutted (Figure 88, Figure 89, Figure 90, Figure 91, and Figure 92). Much of the lower eastern area has been overgrown with grass and weeds, but the accumulation of plant life appears to be quite shallow, as attempts to probe the soil were met with concrete or other solid surfaces less than 3 inches below current ground surface. Through the center of this lower foundation, there appears to be a long linear depression that in some locations is revealed to be a concrete channel of unknown usage (Figure 93). The area covered by the lower foundation depression is nearly a football field's length and the upper section perhaps three quarters of that dimension.

Included within the APE are three buildings, two of which appear historic in nature and to have been contemporaneous with the observed foundations. The southernmost structure is a large warehouse that is longer than the aforementioned foundation. This structure was originally two stories made of brick, but at some point it was expanded and a third cinder block story added (Figure 92); this can be seen in the profile of its south wall, which is clearly visible from the lower portion of the foundation complex. The northernmost building is a three-story brick building that currently serves as an office for Armstrong Kitchen Cabinets (Figure 94 and Figure 88). The building appears to have been contemporaneous with the now-demolished structure and

the warehouse to the south, and its southern façade once formed part of the wall of the now-demolished building (Figure 89). The third building, which adjoins the aforementioned Armstrong headquarters, is of more modern construction and functions as a showroom for the kitchen cabinet retailer.

While foundations were plentiful at this location, observable soil was not. All of the surveyed area was both inside and outside of the foundations, with either paved with macadam or comprised of concrete. As a result of the preponderance of paved surfaces, it was not possible to successfully probe the soil and gain understanding in regard to the subsurface archaeological potential of the APE.

5.3.2 SPIT BROOK STATION AND SIDING

URS conducted the Phase IA field reconnaissance for the proposed Spit Brook Station and railroad siding in Nashua on March 24, 2014. This station location is situated to provide commuter rail access to the residents of South Nashua. There are three components to this proposed construction within the APE: a platform, an expansive parking area, and a rail siding for overnight train storage (Figure 95 and Figure 96). The platform has been designed to fit within the confines of the existing railroad bed; however, the parking area and rail layover locations utilize the large swath of flat land that until recently was home to a Dow Chemical plant. Part of this area is still undergoing mitigation and remediation. The project APE at Spit Brook is situated along the western bank of the Merrimack River, opposite the Green Meadow Golf Club, which occupies the river's eastern bank.

The proposed station platform is situated within the confines of the existing rail bed, which at this location is quite wide, as it once supported several spurs that serviced the Dow Chemical facility (Figure 97). The railroad bed is comprised of highly compacted crushed stone ballast that sits atop a raised berm. The rail bed extends several meters on either side of the extant track. Due to the presence of the crushed stone ballast rail bed, it was not possible to observe the soils in the area of the proposed platform. Similarly, the area slated to function as a rail siding was inaccessible because it fell within the hazmat exclusion zone for the remediation site (Figure 98 and Figure 99).

The proposed parking area for the Spit Brook Station encompasses a large open field that was once part of the Dow Chemical facility. The area was highly overgrown, but was pedestrian surveyed. While no walls or structures were encountered, there was evidence of the previous use in the form of debris piles. The area is exceedingly flat and traversed by a well-worn gravel road that leads to the exclusion zone located in the northern portion of the property (Figure 100). This northern area is surrounded by a large security fence and was unavailable for visual inspection, due to safety concerns about contamination from the site's previous use (see Figure 99). Because of the potential for soil contamination throughout the area, the soil was not probed, so its subsurface archaeological potential and integrity remain unknown.

5.3.3 PHEASANT LANE MALL

URS conducted the Phase IA field reconnaissance for the proposed Pheasant Lane Mall Station and Parking Area in Nashua on March 24, 2014. This station location is situated to provide commuter rail access to the residents of South Nashua. The project APE in this location is comprised of the footprint of the station platform, within the existing rail bed, and a multi-story parking facility at a location that is currently an overflow parking lot (Figure 101). The station platform location is situated within the railroad bed of the existing rail line, which is bordered to the east by the Merrimack River and to the west by the parking lot for the Pheasant Lane Mall, specifically the lots for Sears and Macy's (Figure 102). The southern boundary of the APE is the Massachusetts/New Hampshire border. The area of the proposed platform is contained within the extant railroad bed, which at this location is a wide corridor of highly compacted crushed stone ballast that at present is separated from the mall parking lot by a chain-link fence (Figure 103 and Figure 104). While a meter or so of green space exists between the edge of the rail bed and the fence, this area was inaccessible, and so archaeological potential of the soil was not ascertained. A meter of green space also exists between the parking lot and the railroad ROW fence, is lined with stands of recently planted trees, and serves as a power line corridor with transmission poles located at 100-foot intervals paralleling the railroad bed (Figure 103 and Figure 104). The soil in this narrow available area appears to be imported fill soil contemporaneous with the construction of the mall parking lot.

The proposed parking structure for the rail station is located within the center of a raised parking area along the eastern side of the Sears department store (Figure 105). This southern boundary of the APE—and thus the southern extent of the structure—is the Massachusetts/New Hampshire border. As this area is already paved, it was impossible to examine the soil in this location. The elevated parking area for the Sears store appears to have been created by importing fill and grading the area into a raised parking lot. This conclusion is supported through observation of fill soils along the slope that formed the eastern edge of the parking lot. This eastern edge area was examined because it was the only location not capped by pavement.

6.0 Conclusions and Recommendations

6.1 Concord

6.1.1 Stickney Ave

The literature review conducted for the Concord-North Study Area did not indicate any identified archaeological sites within the proposed Stickney Avenue APE. Similarly, the visual reconnaissance of the proposed APE for the train station and parking facility revealed no direct evidence of archaeological deposits. The majority of the APE was buried beneath extant caps. The proposed parking area is already covered by macadam and functions as a parking area, so the soil in this area is not visible. This pavement does not exclude the possibility that there may be buried cultural materials within the APE, but their presence or absence cannot be readily verified without removing pavement. Beneath the macadam cap, this paved area has the potential to contain culturally sensitive soils, as historic maps have demonstrated this area was once host to several railroad-associated structures. The area immediately along the existing tracks, the extant railroad bed, also has the potential to contain intact cultural resources, provided such resources escaped destruction during the grading for the construction of the railroad bed. If such resources exist, they too are now relatively protected from disturbance beneath a thick layer of compacted crushed stone ballast.

The proposed rail platform and track locations (as detailed in Figure 24) deviate substantially from the existing rail bed, continuing more or less straight across the back of the NHDOT property on a north-south axis. This area is at present quite overgrown and functions as a power line corridor. While initial inspection of the soils indicates that the soils in this area are comprised of fill, the depth of that fill soil was not determined. URS recommends that any grading or major ground-disturbing activities—such as rail bed construction, platform construction, power line pole installation, etc.—taking place outside the current rail bed be preceded by a Phase IB archaeological survey. This survey will illuminate the archaeological potential of the impacted soil and determine if the construction activity will constitute an adverse effect to significant buried cultural resources. Within the already paved ground surface of the APE, URS sees no need for further testing, as the potentially cultural soil lies beneath a protective cap. However, if ground-disturbing activities (like the construction of new buildings) occur within an already paved area, URS recommends a Phase IB survey to assess the potential for intact and buried soils below the existing paving.

6.2 Manchester

6.2.1 Spring Street Station

The literature review conducted for the Manchester-Downtown Study Area did not indicate any previously identified archaeological sites within the bounds of the Spring Street Station APE. Visual reconnaissance of the proposed APE for the Spring Street Station also failed to reveal any direct evidence of buried cultural materials. The majority of the soil within the APE was buried beneath extant caps of crushed stone ballast that comprise the extant railroad bed. The project area is confined to a straight run of railroad bed that parallels Canal Street and is bounded to the

south by Spring Street and to the north by Dow Street. While it is possible that cultural resources may exist beneath the rail bed, the construction plan calls for adding additional fill and pouring a concrete platform on top of the existing rail bed. This approach would eliminate subsurface ground disturbance, and any cultural resources existing underneath a protective railroad bed cap will remain protected by additional caps. In this case, construction of additional soil caps will further shield any cultural materials existing beneath the rail bed at this location, protecting them from disturbance and erosion. The area between the rail bed and Canal Street that is at present a drainage ditch is of some concern. If subsurface work requires moving this drainage channel to (or recreating it in) a new location, URS recommends that a qualified archaeologist monitor this ground-disturbing activity to ensure that no buried cultural materials are adversely affected during the work. The current plan, however, does not appear to impact this existing drainage channel, and visual inspection of this area showed it to be comprised of fill soils and gravel. If construction does not necessitate the creation of a new drainage system for this location, then no further survey is recommended. If future construction plans propose ground-disturbing activities—such as the excavation of platform footings or utility trenches that would remove or go below existing soil caps, like the crushed stone ballast of the extant rail bed—URS recommends a Phase IB survey to identify the presence or absence of significant archaeological material in these areas.

6.2.2 GRANITE STREET STATION

The literature review conducted for the Manchester-Downtown Study Area did not indicate any previously identified archaeological sites within the bounds of the Granite Street Station APE. Visual reconnaissance of the proposed APE for the Granite Street Station did not yield any indication of buried cultural materials. The majority of the APE was buried beneath extant caps comprised of either pavement or compacted crushed stone ballast. The proposed platform location is situated within an extant rail bed that is a thick layer of compacted crushed stone ballast, which in this case is at or slightly below grade. While it is possible that cultural resources may exist beneath the rail bed, the construction plan calls for adding additional fill and pouring a concrete platform on top of the existing rail bed to form a platform. This approach would eliminate subsurface ground disturbance and any cultural resources existing underneath a protective railroad bed cap will remain undisturbed. The platform location is surrounded on all sides by paved surfaces and buildings, so there is no exposed soil to test. The construction of a rail platform at this location would require the removal of extant soil caps and the digging of a footing for the rail platform. As this proposed construction involves the removal of extant soil caps, URS recommends that qualified archaeologists perform a Phase IB survey prior to the commencement of construction. However, if construction can be altered so that the existing soil caps remain in place, then URS recommends no additional survey.

6.2.3 GRANITE STREET LAYOVER

The literature review conducted for the Manchester-Downtown Study Area did not indicate any previously identified archaeological sites within the bounds of the Granite Street Layover APE. The visual reconnaissance of the proposed APE for the Granite Street Layover also revealed no direct evidence of buried cultural materials. The entirety of the APE was buried beneath extant caps comprised of either macadam or compacted crushed stone ballast. The rail sidings at this

location are in some cases already in place, as remnants of a former rail yard at this location that still receives occasional use. No subsurface work at this location should be necessary, as the area has already been graded and modified for the proposed used. The APE is under a blanket of thick and compacted crushed stone ballast lined with in-use and disused rail sidings. Construction in this area should consist of little more than the clearing of scrub brush, the removal of debris, and track repair. None of the aforesaid activities have subsurface impacts. If construction proceeds as planned, URS recommends no additional survey. However, should the construction plan be modified to include sound barriers along the boundary of Riverwalk Drive to lessen noise disturbance to the condominiums situated down slope from the siding, then URS would recommend that a Phase IB testing of the barrier wall locations be undertaken, given the archaeological sensitivity of the Merrimack River floodplain.

6.2.4 QUEEN CITY BRIDGE LAYOVER

The literature review conducted for the Manchester-Downtown Study Area did not indicate any previously identified archaeological sites within the bounds of the Queen City Bridge Layover APE. The visual reconnaissance of the proposed APE for the Queen City Bridge Layover revealed some evidence of modern cultural materials. The majority of the APE was buried beneath extant caps comprised of either Macadam, concrete or compacted crushed stone ballast. The rail layover proposed at this location intrudes upon the remains of a former rail yard which comprises much of the northern end of this project APE. The southern ¾ of the APE is comprised of macadam parking area and the slab concrete remains of a former industrial building. There is a large pile of construction/demolition debris and fill soil sitting atop of the former building location. Debris in the area appears to date the former structure to the later portion of the 20th century, rendering it NRHP ineligible and exempting it from the need for additional archaeological survey. An aerial photograph palimpsest analysis of that area shows that a between 1947 and 1952 a cluster of small buildings occupied the central portion of the APE (Nationwide Environmental Title Research 2014). These structures may be remnants of the Swifts Slaughter Works which is depicted in that location on the D.H. Hurd and Co. Map of 1892. However, a 1965 aerial photograph of the project APE shows that the same area has been cleared and graded, leaving no evidence of these earlier structures (Nationwide Environmental Title Research 2014). However, by 2003 the area has once more been built upon and is the site of a small building which parallels the tracks to the east and is connected to another larger building structure on the opposite side of the tracks via a raised causeway (Nationwide Environmental Title Research 2014). The entire area surrounding the structure back to the existing rail yard area has been by this time covered in macadam. At present there is no trace of this building present on the 2003 aerial photograph except for overgrown dirt pile and scatter of modern demolition debris. This aerial photograph palimpsest analysis reveals that both the macadam and the visible traces of a historic building date to between 1965 and 2003 rendering them too modern to be NRHP eligible and are therefore they need not be considered as cultural resources. The aerial photograph palimpsest analysis of the area at no point shows evidence of the W. Smith house depicted on the Hurd map of 1892, a structure which clips the northwest corner of the APE. A similar palimpsest analysis of historic USGS quad maps from 1905-1985 shows a structure in the location of the W. Smith House up until the grading episode shown in the aerial photographs (Nationwide Environmental Title Research 2014). The last topographic map to show any indication of a structure at this location is dated 1950 (Nationwide

Environmental Title Research 2014). The USGS maps show nothing on the site between 1950 and 1985 indicating that once graded, between the years 1950-1965, the area containing the APE remained vacant until the mid-1980's when the large structure, shown to be associated with the structure on the opposite side of the tracks in the 2003 aerial photograph, was constructed. The now demolished building within the APE was built sometime between 1985 and 2003. It was subsequently demolished between 2003 and 2014. The grading episode of the 1950-1960's appears to have eliminated the archaeological evidence of the earlier structures depicted on the D.H. Hurd map of 1892, and subsequent introduction of soil caps like pavement, concrete and crushed stone ballast have covered the area making investigation of any potential surviving evidence of these earlier structures impractical. Whether or not evidence of these earlier late-19th and early-20th century structures remain beneath the extant soil caps is largely irrelevant. To proceed with construction there is no need for subsurface work because it has already been graded during its previous occupation which has more or less prepared the area for its proposed use as a layover. As no grading is necessary there is no reason that the existing soil caps (i.e. macadam, concrete and crushed stone ballast) will not remain in place, capping any potentially undisturbed soils that might lie beneath. Importation of new crushed stone ballast material to create a bed for the proposed rail layovers at this location can be accomplished without removal of the soil caps and disruption of the soil beneath. This additional cap of crushed stone ballast should further protect any potential resources that might exist at this location. If construction proceeds in this manner, then URS recommends no additional survey. However, should the construction plan be modified to include substantial grading that would necessitated the removal of existing soil caps, then URS would recommend that a Phase IB testing of be undertaken, given the archaeological sensitivity of the Merrimack River floodplain.

6.2.5 CEMETERY LAYOVER

The literature review conducted for the Manchester-South Study Area did not indicate any previously identified archaeological sites within the bounds of the Cemetery Layover APE. Visual reconnaissance of the proposed APE for the Cemetery Layover revealed no direct evidence of archaeological deposits. The majority of the APE is buried beneath an extant cap of crushed stone ballast that comprises the railroad bed. The current construction plan for this layover calls for the realignment of the main line, the reestablishing of a secondary set of tracks along the main line, and the construction of an additional rail siding. There is sufficient space for this within the extant rail bed to move the main line and establish two sidings, but the additional two new rail sidings along the eastern side of the track will require an expansion of the rail bed. While few subsurface impacts are anticipated within the majority of the APE footprint that falls within the extant rail bed, the expansion of the rail bed and construction of an access road and maintenance station could have an adverse effect. The terrain to the east of the extant rail bed is a sprawling wetland at a foot of a large hill. The construction of additional rail bed for sidings at this location has the potential for environmental and cultural impacts. The proposed location of an access road from Crescent Road also passes through a sensitive area, as it crosses a small stream. If the existing access road running along the riverbank between the tracks and the water were to be altered or widened to accommodate construction on the rail line, this too could have an adverse effect. Should plans to construct the layover at this location move forward, URS recommends a Phase IB survey of the APE to determine the impact that any construction activity might have on potential buried archaeological resources. The potential for pre-contact materials

here is high, given the location in a floodplain of the Merrimack, its proximity to the rich resources offered by the adjacent wetland, and the opportunities for riverine exploitation afforded by the presence of Carthagina Island, which creates a narrow channel along the bank paralleling the track and may have attracted pre-contact peoples. As a result of these factors, the area along the bank and to the west of the track must be considered archaeologically sensitive, and any construction activities that would impact this area would require testing to determine if there is an adverse effect to cultural resources.

6.2.6 WASTEWATER TREATMENT PLANT LAYOVER

The literature review conducted for the Manchester-South Study Area did not indicate any previously identified archaeological sites within the bounds of the Wastewater Treatment Plant Layover APE. Visual reconnaissance of the proposed APE for the Water Treatment Plant Siding revealed no direct evidence of buried cultural materials, largely due to the fact that the entirety of the APE is contained within an extant rail bed and, as a result, all of the soils lie beneath a thick layer of compacted crushed stone ballast. The proposed construction of the rail siding at this location will not entail any subsurface impacts, and the existing crushed stone ballast caps will remain intact. As there is no threat of soil disturbance, there is no potential for adverse impact on buried archaeological resources posed by the construction of the rail layovers. However, the construction of the small maintenance shed near the rail crossing at this location has the potential to entail subsurface impacts. If this proves to be the case, then a Phase IB survey limited to the area of the maintenance building should be undertaken. If construction of the maintenance shed does not entail subsurface disturbance, then URS recommends that no further survey is necessary at this location.

6.2.7 MHT AIRPORT-RAY WIECZOREK DRIVE STATION

Visual reconnaissance of the proposed APE for the MHT Airport-Ray Wieczorek Drive Station revealed no surface indication of archaeological sites. While no surface evidence of archaeological deposits was visible, it is important to note that Site 27-HB-211 is mapped within the MHT Airport-Ray Wieczorek Drive APE, and was identified and evaluated through subsurface testing during the cultural resource survey for the recently constructed Raymond Wieczorek Drive Bridge (Goodby 2000, 2001, 2005). The site was characterized as a low-density artifact scatter representing ephemeral occupations during the Late Archaic, Middle Woodland, and Late Woodland periods. Based on Phase II studies, the investigated portion of the site was recommended to be not eligible for listing in the NRHP (Goodby 2005). Nevertheless, the presence of such a resource in such close proximity to the proposed APE for this project demonstrates the subsurface pre-contact archaeological potential of the area. The visual reconnaissance of the APE that was conducted found that the majority of the APE is contained within an extant rail bed and, as a result, its soils are capped by a thick layer of compacted crushed stone ballast. The proposed construction at this location calls for the addition of an at-grade rail platform that would be confined to the existing rail bed. As no soil outside of the rail bed would be disturbed during the construction of the platform, there is no potential for effects to archaeological sites. The proposed parking area and shuttle turnaround are to be placed within the footprint of the Ray Wieczorek Drive Bridge, recently constructed in 2013. As previously described, the area to the east of the APE was the subject of Phase I and II

archaeological investigations prior to bridge construction; Site 27-HB-211 was identified and investigated during this work. As the MHT Airport-Ray Wieczorek Drive Station APE lies just to the west of this surveyed area, it is possible that portions of Site 27-HB-211 may extend into the current APE (Figure 106). Because current plans involve construction of an at-grade rail crossing with no associated excavation, URS recommends that no further archaeological investigations are necessary within the APE. However, if detailed project plans include the excavation of footings and trenches for utilities that extend beyond the existing rail bed crushed stone ballast or require its removal, exposing potentially undisturbed soils, a Phase IB survey should be undertaken to determine whether a portion of Site 27-HB-211 is present in the APE.

6.3 Nashua

6.3.1 Crown Street

The literature review conducted for the Crown Street Study Area did not indicate any previously identified archaeological sites within the bounds of the Crown Street Station and Parking Area APE. The visual reconnaissance for the proposed rail platform at the Crown Street station in downtown Nashua revealed that the location of the proposed station is situated within an extant railroad bed comprised of crushed stone ballast. The soil in this area was capped by this crushed stone ballast rail bed and, thus, no evidence of buried cultural resources was evident within the footprint of the proposed rail platform. The proposed construction of an at-grade rail platform at this location will not disturb any buried soils that are capped by the rail bed. Since no soil will be disturbed during the construction of the platform, URS recommends that no further cultural survey is necessary within the footprint of the proposed platform.

While no previously identified sites exist within the Crown Street APE, visual reconnaissance of the APE for the Crown Street Station parking facility in downtown Nashua revealed direct evidence of cultural resources. Two-thirds of the area slated for parking is comprised of the archaeological remains of former industrial buildings, the foundations and floors of which were clearly visible during visual reconnaissance. The proposed construction for the parking area calls for the grading of the area. At present, the APE is comprised of a complex of foundations and two historic buildings that appear to be contemporaneous with the archaeological foundations. The proposed construction in this area has the potential to adversely affect this historic foundation complex. In order to determine significance of the observable archaeological resources, URS recommends that a Phase IB survey be completed at this location. Such a survey would provide the necessary data to assess the significance of the site. Historic research described in a previous section demonstrates that this area has a long industrial history spanning much of the nineteenth and twentieth centuries. The recommended Phase IB cultural resource survey will assess the potential of this site to contribute to the understanding of the industrial development of Nashua.

6.3.2 Spit Brook Station and Layover

The literature review conducted for the South Nashua Study Area revealed the presence of Site 27-HB-354, the Spit Brook Site, within the bounds of the Spit Brook Station and Layover APE. Visual reconnaissance of the proposed APE for the Spit Brook Station and Layover in South

Nashua, however, revealed no evidence of archaeological materials within the footprint of the proposed rail platform. The proposed rail platform is entirely situated within the extent of an existing railroad bed. No soils were visible in this area, and any potentially significant cultural deposits that might exist beneath the rail bed have been capped by a thick layer of highly compacted crushed stone ballast. The rail bed within the footprint of the proposed platform is quite wide, having previously included sidings that serviced the now-demolished Dow Chemical facility that once stood to the west of the rail line. There is no adverse effect posed by the construction of the station platform, as construction activities will not disturb any soils. URS recommends that no further archaeological survey is necessary in this portion of the Spit Brook APE.
